white iodide of potassium may be immediately obtained. The deposit of calcareous carbonate when well washed does not contain any iodine, as may be seen on adding nitric acid, and exposing paper imbued with starch to the effervescence produced. The precipitate of peroxide of iron of the first operation shows, by means of the same reaction, that it does not contain any iodine. By the process which is now pointed out, a pure and white iodide of potassium is immediately obtained, whilst the operations are much diminished, and more easily performed.

The iron is added to prevent the production of iodate of lime.—*Pharmaceutical Times.*

IODIZED OIL.

This preparation has superseded the other forms of iodine at the Val-de-Grace. M. Marchal, (De Calvi,) reasoning from the fact of the virtues of cod-liver oil being due to the small portion of iodine it contains, concluded that a far more useful preparation of this substance than the iodide of potassium is found to be might be made by combining it with an organic body. In this way a more complete assimilation of the substance, or, at all events, its longer retention in the economy, might be secured. He chose an oily body, because this, forming an emulsion with the bile, would allow of the substance being digested in the small intestines, and enable the stomach to become relieved of its presence. In this way far larger doses can be administered, if requisite, without irritating the latter organ; while the iodine is eliminated by the urine much more slowly and in far less quantities than is the case with the iodide. The trials which have been made are very satisfactory in their results, the progress of the cure of buboes and other glandular enlargements being much expedited. The iodide is dissolved in fresh almond oil as wanted, in the proportion of one part to fifteen; and this is afterwards worked up into an almond emulsion. The minimum dose is one grain.—*Gazette des Hôp.*, 1848, No. 13.—*Pharm. Times.*

LIFE-ASSURANCE CERTIFICATES.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I beg to forward to you the accompanying copy of a correspondence between the Secretary of the Temperance Provident Institution, 39, Moorgate Street, London, and myself, and likewise a copy of an agreement entered into some years ago by the medical men of this town. I am inclined to think, that if a similar agreement were adopted *and adhered to* by the profession generally, we should not so frequently have to complain of being placed by Assurance Societies in collision with our patients, and that, too, without receiving any remuneration for the valuable information which they obtain from us.

Temperance Provident Institution,
39, Moorgate Street, London.

SIR,—A proposal having been made to this Institution for the admission of Mr. Gilbert Dallison as a member, and reference having been made to you for information respecting his present and general state of health, I have to request on his behalf that you will favour the Directors with answers to the enclosed queries. [16 queries.] Permit me to add that it is important to the party himself, that every question should be answered in as full and as correct a manner as possible.

As communications of this nature are considered to be strictly confidential, and a reason for rejection is never assigned, a perfect reliance may be felt, that should the tendency of your answers be such as to induce the Directors not to accept the proposed candidate, the purport of them will never be suffered to transpire, or to become in any way the subject of observation.

I have further to solicit that you will have the kindness to return the accompanying certificate, addressed as above, at your earliest convenience.

I am, &c.,
THEODORE COMPTON, Secretary.

May 23, 1848.

Derby, May 24, 1848.

SIR,—I have just received the form of certificate of health which you request me to fill up for Mr. Gilbert Dallison.

In consequence of the frequent applications made to medical men by Life Assurance Societies, for information respecting the health of persons desirous of having their lives insured, the medical men of this town have entered into an agreement that they *will not* answer the list of queries sent to them on such occasions unless they are accompanied with the fee usually given to the appointed referree of such societies.

Waiting your reply, I remain, Sir, &c.,
JOHN JONES.

Theodore Compton, Esq.

London, May 25th, 1848.

SIR,—In reply to your letter I beg to state that we require every person to give us satisfactory evidence of his health, I can, therefore, only refer you to your patient, if you will not give your answers without a fee. Should we require any special advice, or any examination, we shall be quite ready to pay you, but we cannot think your demand tenable for merely giving such *information* as you have at hand.

I am, Sir,
Your obedient servant,
THEODORE COMPTON.

J. Jones, Esq.

Derby, May 27, 1848.

SIR,—In accordance with your suggestion, I have applied to Mr. Dallison for a fee before I answer the queries contained in the form of certificate of his health forwarded by you to me, which he declines paying, I am, therefore, under the necessity of refusing to fill up the certificate as requested. In doing so I beg to state that I consider Assurance Societies ought not to object to pay the remunerating fee to the medical attendant of the applicant for assurance to whom they apply for information, for the following reasons:—

1st. The information is of the utmost importance to the interests of such societies.

2. The usual medical attendant can generally afford such information as cannot be obtained from any other source.

3. "As communications of this nature are considered to be strictly confidential," the transaction is, in my opinion, entirely and exclusively between the society and the medical man to whom application is made.

I have received from you a similar certificate for Mr. John Hendley, which, for the reasons stated as referring to Mr. Dallison, I must also decline filling up till I receive a fee to the same amount as you are in the habit of paying to your regularly-appointed medical referree.

I am, Sir,

Your most obedient servant,

Theodore Compton, Esq. JOHN JONES.

Copy of Agreement.

It being a common practice for agents of Life Insurance Companies to apply for information respecting the health of the applicant for insurance to his usual medical attendant, and in so doing present a formula of queries to be filled up by him, with an assurance that if an unfavourable report should be made, the applicant shall not be acquainted with the source from whence the Company have derived their information, thus constituting the transaction a private one between the Company and the medical man; and as in many instances the Company refuse to give a compensating fee for information thus obtained, we, the undersigned medical practitioners, of Derby, agree for the future, never to respond to such applications, without receiving from the Company's agents the same remunerating fee as is given to their regularly appointed medical referree:—

W. E. Forrester, M.D.; Thomas Bent, M.D.; Wm. Baker, M.D.; James Heygate, M.D.; Douglas Fox, surgeon; William Bennet, surgeon; Edward Charles Rudkin, surgeon; John Wright, surgeon; John Hill, surgeon; S. W. Fearn, surgeon; Charles Borough, surgeon; John Lindley, surgeon; John Johnson, surgeon; J. Whitaker Johnson, surgeon; John Jones, surgeon; Augustus G. Greaves, surgeon; Henry F. Gisborne, surgeon; Robert Hamilton, surgeon; John Webster, surgeon; Thomas Harwood, surgeon; Allen Borman, surgeon; Thomas Buxton, surgeon; Edward Hoskins, surgeon; Joseph Butler, surgeon; Wm. Moore Wooler, surgeon.

If you agree with me in thinking that the publication of the above might be useful, I shall feel obliged by its insertion in the *Provincial Journal*; and, perhaps, you will not think it too much trouble to cause it to be forwarded for insertion also in the *Lancet*.

I remain, Sir,

Your obedient Servant,

Derby, June 5, 1848. JOHN JONES.

Medical Intelligence.

THE EPIDEMIC CHOLERA.

Accounts from Vienna mention that the cholera has appeared at Galatz, and that 23 persons had been almost simultaneously attacked by the disease in that town.

REPUBLICAN LIBERTY.

M. Foville has been dismisssed from his appointment of first physician to the Charenton. These proceedings of the French government in depriving men of the highest reputation and talent of their offices, on account of political opinions, are but little consonant to English ideas of liberty. Our Continental neighbours would seem to have yet to learn, that freedom of thought and opinion, without being subjected to pains and penalties, is quite as essential to true liberty, as the extension of the elective franchise to all the subjects of the state, or the admission of all to the deliberative council of the nation, without regard to qualification and fitness.

DR. BERNCASTLE'S TESTIMONIAL.

The following additional subscriptions have been received to the fund for this object:—

Dr. Elliotson, F.R.S.	£2	2	0
W. Clark, Esq., Sutton, ...	1	1	0
R. Espie, Esq., R.N.	0	10	6

APPOINTMENTS.

Henry Taylor, Esq., has been elected Surgeon to the Nottingham Dispensary, in the room of Mr. Robert Davison, deceased.

Dr. Cursham and Dr. Theophilus Thompson have been elected Physicians to the Hospital for Consumption, at Brompton; and Dr. Quain, Dr. Cotton, and Dr. Bower, Assistant-physicians to the same Institution.

M. Trousseau is appointed Physician to the Hôpital des Enfans Malades, in the room of M. Guersant, deceased.

ROYAL COLLEGE OF SURGEONS OF IRELAND.

The following gentlemen have been elected officers for the ensuing season:—

PRESIDENT—Robert Harrison; VICE-PRESIDENT—Andrew Ellis; SECRETARY — Alexander Read; COUNCIL — Richard Carmichael, Samuel Wilmot, Alexander Read, William Auchinleck, James W. Cusack, Arthur Jacob, W. H. Porter, William Tagert, R. C. Williams, L. Armstrong, Leonard Trant, Francis Rynd, Robert Adams, James Barker, William Colles, John H. Power, Lewis E. Lipsett, John Macdonnell, Maurice Corr.

ROYAL COLLEGE OF PHYSICIANS.

HARVEIAN ORATION.

The Harveian Oration is appointed to be read on Saturday, June 24th, by Dr. Francis Hawkins.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, June 2nd, 1848:—J. W. Dew; W. A. Gillow; J. Adams; W. Gilbee; H. T. Parke; J. Gunson.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, May 25th:—George Francis Cooper; George Manning, Canada; Peter Hinckes Bird, Birmingham; Robert Abercrombie, Manchester.

OBITUARY.

Died, in January last, Matthew Hall, Esq., M.R.C.S., of Wortley, near Leeds, a Member of the Provincial Medical and Surgical Association.

May 18th, at Scariff, in the county of Clare, aged 44, of fever, Thomas Smith, M.D.

May 24th, at Tunbridge, aged 53, William James West, Esq., Surgeon.

May 24th, aged 52, of fever, John Boast, Esq., M.R.C.S., of Southwark.

Lately, M. Alphonse Dupasquier, Professor of Chemistry at the Medical School of Lyons.

Hospital Elections and Medical Reform, addressed to the Governors of St. George's Hospital, and to the Profession. By Edwin Lee, Fellow of the Royal Medical and Chirurgical Society, &c. &c. London: Churchill. 1848. 8vo. pp. 32 and 12.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNIVERSARY MEETING.

The Anniversary Meeting of the Provincial Medical and Surgical Association is appointed to be held at Bath, on Wednesday, August 9th, and Thursday, August 10th, when George Norman, Esq., F.R.C.S., of Bath, will be proposed as President for the ensuing year, in the room of Dr. MacMullen, the President-Elect, who is compelled from ill health to resign the appointment.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscription for the current year, or who are in arrears, are requested immediately to forward the amount due, either to the Secretary of the District in which they reside, or to the Treasurer or Secretary of the Association, as the accounts are now about to be made up for the Annual Meeting.

ROBERT J. N. STREETEN, Secretary.

TAUNTON AND SOMERSET BRANCH.

ANNUAL MEETING.

At the Annual Meeting of the Taunton and Somerset Branch of the Provincial Medical and Surgical Association, held at Taunton on Wednesday, May 7th, 1848, Dr. Brock, President, in the chair, A. F. Edwards, Esq., of Wiveliscombe, was appointed President-Elect. Messrs. Alford, Edwards, Gillett, Kelly, Kidgell, Ling, Randolph, with the President and the Secretary, form the Council for the ensuing year. Dr. Woodforde was appointed Honorary Secretary and Treasurer. Wiveliscombe was fixed on as the place of meeting for the year 1849.

SUFFOLK BRANCH.

ANNUAL MEETING.

The Annual Meeting of the Suffolk Branch of the Provincial Medical and Surgical Association will be held at the Guildhall, Bury St. Edmunds, on Friday, June 16th, T. G. Hake, M.D., President, in the chair.

C. R. BREE, Hon. Sec.

Stowmarket, May 27, 1848.

BATH AND BRISTOL BRANCH.

ANNUAL MEETING.

The Annual Meeting of the Bath and Bristol Branch of the Provincial Medical and Surgical Association will be held at the Royal Literary and Philosophical Institution, Bath, on Thursday, June 22nd, at 2, p.m., Farnham Flower, Esq., President, in the chair.

JOHN S. BARTRUM, Secretary.

SOUTH-EASTERN BRANCH.

ANNUAL MEETING.

The Annual Meeting of the South-Eastern Branch of the Provincial Medical and Surgical Association will be held at Tunbridge Wells, on Wednesday, June 28th.

As Tunbridge Wells in itself may be supposed to have an especial interest for gentlemen from a distance, for those who can arrive over night, or early in the morning of the 28th, there will be a breakfast party at nine o'clock, at the Sussex Hotel.

I. HARGRAVES, President,
THOMAS MARTIN, Reigate,
Secretary.

TO CORRESPONDENTS.

Communications have been received from Dr. Wardell; Mr. Crompton; Dr. Oke; Dr. H. T. Castle; M.R.C.S.; Mr. F. S. Garlick; Mr. J. Jones; Mr. Daniell; Dr. Blackmore; Mr. W. Bush.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

CLINICAL LECTURE ON DIABETES.

Delivered at King's College Hospital,

By R. B. Todd, M.D., F.R.S., Fellow of the Royal College of Physicians, &c.

(Reported by S. J. A. Salter, Esq., M.R.C.S., A.K.C.,)

Gentlemen,—To-day I have to trouble you with the remaining particulars and termination of the cases of our two diabetic patients, Hardy and Bowles, both of which have come to a conclusion, as far as our clinical study is concerned; the one patient having left the hospital, is consequently removed from our observation, and, to a great degree, from our treatment also, though we still occasionally see him as an out-patient; the other having terminated fatally, in consequence of inflammatory disease of the kidneys, having been produced by the patient's violation of the rules of diet laid down for him, and his too liberal use of spirituous liquors. I shall, therefore, in addition to the clinical remarks, be able to communicate to you some interesting points on the morbid anatomy of diabetes.

You are aware that these men have been subjected to the most rigid dietetic treatment, and that the plan which I proposed has been carried out to the fullest extent that was possible. I will explain to you what this mode of treatment was. The patients were both put into a separate ward; it was sufficiently large, airy, and light, and in this room they were locked up; they went into this ward on the morning of the 22nd of November, and remained there until the 18th of January, a period, both days being included, amounting to about two months, being fifty-eight days. The door was kept constantly locked, and no one was allowed access to the patients, except the house-physician, the clinical clerks, and the nurse; and I chose the nurse to attend on these men, whom I believe to be a thoroughly efficient and trust-worthy person,—indeed, the most so of those in the hospital. Occasionally they took exercise, at first in a cab, and afterwards, when they were strong enough, on foot; but on these occasions they were always accompanied either by the nurse, who was sent with them to prevent them from taking any improper food or drink, for had they done so, it would have upset all our calculations, and we could not have arrived at any definite conclusion, as to the effect of the dietetic mode of treatment we had been pursuing. By this, I believe we precluded every means of imposition; and I think there certainly can be no doubt, but that we knew everything our patients were taking. It is quite necessary to observe all these precautions, for the appetites of diabetic patients are so enormous, and their craving for just those kinds of food which are most improper for them, is so great, that if any possible opportunity of getting such diet be given, they are sure to take advantage of it; their cravings for saccharine and amylaceous food are so great, that they almost deceive themselves, and though they may wish to obey the injunctions of their doctor, their impulses are so strong, that, have they a chance, they will in this particular, disobey him.

I am quite sure that my friends, the house-physician and my clinical clerks, have been too anxious to further my wishes, in the treatment of these patients, not to have exercised due vigilance over them, to prevent them from procuring any food, that I had not ordered them; and if the nurses under whose surveillance they took their exercise, have done their duty, as indeed, I believe they have, then, any inferences to which we may come, relative to the effect and value of the mode of treatment we have adopted, that suggest themselves, will be without fallacy on that score. I am, myself, quite satisfied with our security.

On the morning of the 22nd of November, 1847, they were removed into their solitary ward; but it was not till the next day, that the strictly animal diet was adopted.

I will first, gentlemen, call your attention to Hardy's case. On the day of his admission into the new ward his diet was the following:—

For *Breakfast*—Milk, 1½ pint
Tea, 1 pint,
Bread, 8 ounces.
Dinner—Meat, 14 ounces
Eggs, 2
Porter, 2 pints.
Supper—Meat, 8 ounces
Tea, *ad libitum*.

At this time Hardy was in extremely low condition; he was much emaciated, he suffered greatly from thirst, and was often disturbed in the night by the urgency of his thirst, and the necessity for frequent micturition; he was excessively weak and languid, and could hardly walk up stairs. Three days previous (the 19th,) he was weighed, and it was found that his weight was only 128 pounds, it having been 127 on the 14th, and 129 on the 6th. On this day he drank nine pints of fluid, and passed eleven pints of urine, the specific gravity of

which was 1.034, and which, to all the ordinary tests, yielded unequivocal evidence of holding a large quantity of sugar in solution.

Being anxious to ascertain what amount of sugar might be found in the matters ejected from his stomach, I ordered him an emetic, consisting of twenty-five grains of sulphate of zinc, to be taken on this evening, (the 22nd.) This emetic, however, did not make him vomit, (the same was the case with Bowles,) but made him feel slight nausea for about one hour.

On the 23rd the report states that he was rather weaker; he had had no sickness from the emetic, but it had occasioned profuse diaphoresis in the night, which had materially interfered with his rest. During this day he had no sweet taste in the mouth, less thirst, the saliva not so acid, the tongue cleaner, and the mouth more moist. The quantity of liquid drunk was nine pints, and that voided was eight pints, of specific gravity 1.038. His diet for this day was—

At *Breakfast*—Eggs, 2
Beef tea, 1½ pint.
Dinner—Meat, 14 ounces
Beef tea, 1 pint.
Tea—Meat, 6 ounces
Eggs, 2
Beef tea, 1½ pint.
Supper—Meat, 8 ounces
Beef tea, ½ pint.

On the 24th he had passed a good night, having been disturbed only twice to make water,—this was a great and rapid change in this particular symptom. Very early in the morning he was attacked with a violent itching of the skin, accompanied by an eruption resembling urticaria, which was probably produced by the very different diet he was then taking, from what he had previously. The patient stated that he felt unusually well, and differently from what he had at any time previously, during his residence in the hospital. The skin was slightly moist; the saliva abundant; tongue clean; pulse 90; urine six pints and a half, eight pints of liquid having been drunk; it was acid, and the specific gravity ranged, during the day, from 1.030 to 1.032; one specimen was passed of 1.021.

The following diet was fixed for him—

Breakfast—Meat, 1 pound
Water, *ad libitum.*
Dinner—Meat, 1 pound
Water, *ad libitum*
Greens.
Tea—Meat, 6 ounces
Eggs, 2
Water, *ad libitum.*
Supper—Meat, ½ pound.

He was also to have two bottles of Carrara water during the day.

On the morning of this day he also took an emetic, (Zinci Sulphatis, gr. xxv.;) it did not make him vomit, but produced slight nausea. About 9 o'clock, p.m., he had another attack of cutaneous itching, but it was less intense than the previous one, and only lasted half an hour.

On the 25th the patient felt still better, he had passed a comfortable night, the sulphate of zinc having caused only very slight diaphoresis; he had been disturbed but twice to pass water; the tongue clean and moist; skin damp; thirst less. The urine, which was in quantity eight pints and a quarter, had totally changed, it now contained *no trace* of sugar, and this was the first instance of a specimen of this man's water being destitute of that substance; its specific gravity was 1.028.

From this time his general symptoms underwent a decided change, constantly and steadily improving. The urine became much less abundant; and I would here draw your attention to some of the most striking instances of its diminution in this table, and in showing you this I would also remind you, that on the 19th of October he drank* ten pints ten ounces of liquid, and passed seventeen pints eight ounces of urine; and on the 22nd of November nine pints were drunk, and eleven pints passed; and three days before twelve were passed, while nine were drunk; and I say, remembering how large was the quantity of fluid drunk and passed just previous to this patient entering the new ward, and how fixedly it kept at that high amount, the immediate diminution, and steady decrease, which it subsequently underwent, are very striking:—

Date,	Quantity drunk.	Quantity voided.
Nov. 10	144 ounces	192 ounces.
„ 22	144 „	176 „
„ 24	128 „	104 „
„ 26	120 „	92 „
„ 29	104 „	92 „
Dec. 5	80 „	68 „
„ 9	48 „	80 „
„ 10	48 „	64 „

During the whole of his sojourn in this ward, the quantity of urine passed kept very steadily to about five pints, (80 ounces,) the thirst also became much less, and, as you see in the above table, he did not drink half the quantity of fluid he had at one time; three or four pints would often satisfy him. The saliva was much more abundant, and was less acid; the pulse too had greatly lessened in frequency, and the diminution in its rapidity seemed to keep pace with the improvement in his other symptoms: thus, on November 24th, the pulse was 90; on the 30th, 80; on the 3rd of December, 84; on the 5th, 70; on the 6th, 72; and on the 8th it was 72 likewise. I shall presently show you that a retrograde course in his health, and a partial return to his former mode of life, had the effect of rendering his pulse more frequent and permanently so. The patient at this time (that is, during December,) was much less often troubled to pass his water; he was obliged to get out of bed, during the night, once—more rarely twice, sometimes not at all. Occasionlly he suffered from a violent itching sensation of the skin; this occurred chiefly at night, when warm in bed, and generally when he perspired freely; it was unattended by any cutaneous eruption, and did not appear to be connected with any obvious cause.

Early in December, Hardy took walking exercise along the corridor in the hospital, under the surveillance of the nurse; subsequently his exercise consisted in a ride in a cab, on which occasions he was

* The pint spoken of in these lectures is sixteen ounces.

also accompanied by the nurse. He gained strength so rapidly, that by the 18th or 19th of the month he could take walks of two miles daily, and accompanied by comparatively little fatigue. This change is truly remarkable; for when first he went into the separate ward, he could hardly walk up stairs.

Another very important improvement which occurred in this patient was, that he gained flesh and consequently increased much in weight. I have already told you, that when he went into the new ward, or, what amounts to pretty much the same, three days previous to that, he was weighed, and his weight was 128 pounds; fourteen days after that he was again weighed, and he had then increased half a stone in weight. The following table shows the progress he made in this particular:—

Date.	Weight.
Nov. 19	128 pounds.
Dec. 7	135 „
„ 23	136 „
Jan. 6	138 „
„ 13	140 „
„ 25	144 „

Thus, you see, in about two months he gained a stone and two pounds in weight.

From the 24th of November up to the 25th of December, his diet was very nearly what was fixed for him on the former of those dates, with these exceptions, that he has occasionally had a small quantity of water cresses, and, at other times, he has had no vegetable at all for several days together, not even greens. His meat consisted of roast beef, roast mutton, mutton chops, beef steaks, veal, and occasionally fish. This was the case from the 15th to the 24th of December.

On the 25th of December, (Christmas day,) Hardy pleaded very hard for me to allow him some pudding, and I could not refuse him any longer, so he accordingly had one slice of pudding. This change in diet produced some alteration in his general symptoms; the pulse became quicker, and he was more thirsty, but there was no increase, either in the quantity or specific gravity of the urine. The most remarkable of these changes was the greater frequency of the pulse; it rose from that time, and never, on any subsequent day, while he remained with us, did it fall as low as it had been for many days before. On the 25th of December, the pulse was 76; on the 28th, 90; on the 29th it was 92; on the 30th, 94; on the 1st of January it rose to 96; and on the 4th to 100. During this time (from Christmas-day to the 4th of January,) he had daily a slice of pudding; but I then interdicted it, and substituted for it a little arrow-root, which he did not like, and he ate very little of it; the result was, that on the 5th of January the pulse fell to 90, on the 7th to 86, and on the 8th to 80. On the evening of this day, being very hungry, he ate all his arrow-root; and not only his own, but also that of his companion; and the next day (the 9th,) his pulse rose to 98, on the 10th it was 96, and it ranged, ever afterwards, between that number and 104, never sinking below 96, and generally much above it, averaging 99 or 100.

During the time our patient was subjected to this mode of treatment, the specific gravity of his urine fell very considerably, (you will bear in mind that its healthy range is from 1.015 to 1.025;) it once reached as low as 1.018. The following are some of the records which have been kept by my clinical clerk:—

Date.	Specific Gravity. Night.	Morning.
Nov. 10	1.036	1.037
„ 23	1.038	1.025
Dec. 2	1.029	1.032
„ 13	1.026	1.028
„ 23	1.026	1.026
Jan. 2	1.019	1.024
„ 3	1.026	1.026
„ 14	1.021	1.023
„ 15	1.018	1.025
„ 18	1.019	1.028
„ 19	1.023	1.028
„ 23	1.026	1.026

On the 18th of January, as the room in which my patients had been confined was wanted for other purposes, Hardy and his companion were removed into Rose Ward. For a few days previous to his entering the common ward I had allowed him a little bread, which he had taken without any alteration of his symptoms, but he now took it in larger quantity, and this produced an increase in the amount of his water, from five pints, which it had been previously, to seven pints; there was scarcely any increase in its specific gravity; the pulse was quicker.

I was anxious to ascertain what was the amount of sugar existing in the urine, relatively to its other constituents, and the quantity of liquid that kept it in solution; and whether it underwent any variation in proportion to the quantity of the urine, or the severity of the other symptoms. This could only be known by a careful *quantitative* analysis, made from time to time. The process, by which the sugar is separated from the other principles in the urine, especially from urea, is tedious and difficult, and the task has been kindly undertaken for me by Mr. John Bowman, and was prosecuted in the laboratory at King's College. I will now read the quantities of sugar, *per cent.*, which he found in the several specimens of urine he examined.

Date.	Amount of sugar in the urine, *per cent.**	Date.	Amount of sugar in the urine, *per cent.**
1847.		1848.	
Nov. 30	3.50	Jan. 10	3.60
Dec. 1	4.53	„ 13†	2.85
„ 6	4.07	„ 18	3.40
„ 8	4.60	„ 19	3.39
„ 15	3.80	„ 24	3.39
„ 17	3.10	„ 21	3.41
„ 21	4.00	„ 31	3.36
„ 24	3.91	Feb. 10	3.35

* The urea was never more than 0.1 to 0.2 per cent.

† For the analysis on the 13th of January I am indebted to Mr. Beale; he further examined the urine quantitatively, as to the amount of its other matters. The following is the result:—

Diabetic Urine—(Hardy.)

Reaction, acid.	Specific Gravity, 1.021.
Water	94.600
Urea, Uric Acid, Extractives	2.154
Sugar	2.850
Fixed Salts	.376
Loss	.020
	100.000

You must observe that, for the most part, there was but slight difference in the per-centage amount of sugar, which the urine contained, and what little difference did occur appeared quite irrespective of the quantity of urine passed, or liquid drunk, or of his condition and symptoms generally. Remember, I am speaking of the *per-centage*, and not of the absolute amount of sugar voided.

And now, gentlemen, that I have troubled you with such lengthened and elaborate details, I will make some general deductions from them. I have come to the following conclusions:—

1st. That the change to an exclusively animal diet was very well borne. It produced no fever, as from common prejudice we might have been led to anticipate, and especially taking into consideration the large quantity taken,—about 3lbs. a-day; but, instead of fever, the pulse steadily and regularly lessened in frequency, and did not again rise till he had violated the strict law as to his diet which I had laid down for him, and partially returned to his former mode of feeding. Primary digestion was very well performed—wonderfully so, when we consider the large quantity of food taken in, and the peculiar character of that food.

2ndly. That the most marked effect upon the secretions, and upon the symptoms generally, was produced *immediately* after the change of diet. If you compare his condition at two or three days after we commenced our new mode of treatment, with what he was at a fortnight, (excepting his increased weight and strength, which of course must be gradual,) you will see little difference. Three days after his admission into the separate ward, the urine diminished from 176 to 92 ounces; his skin, which had previously been dry and harsh, was moist and soft, and at night he had abundant perspiration; his mouth, before dry and clammy, was now moistened by plentiful saliva, and this, too, was of a more natural character, for it was less acid. All this occurred in the first two or three days. The increase of weight which the patient underwent must necessarily occupy some time; but still, it is to be remembered, that in the first fourteen days he gained 7 pounds, while he only gained 9 pounds in forty-eight days afterwards. This shows what a marked effect this mode of treatment had upon the disease immediately upon its establishment.

3rdly. The next deduction that I would make from the details of this case, is relative to the quantity of sugar which Hardy voided in his urine. Now, while the *per-centage* amount of that substance underwent but a trivial alteration, so that any given quantity of his water may be said to have contained nearly as much sugar on any one day as the same measure did on any other day; still, it must be remembered that the urine diminished greatly in the amount daily passed, and consequently the aggregate mass of sugar eliminated, and probably, also, generated, must have diminished in the same direct proportion. Take, for instance, these examples:—On the 22nd of November, 11 pints (176 ounces,) of urine were passed, and they contained 6.07 ounces of sugar; on the 30th of the same month, 6 pints and 12 ounces (108 ounces in all,) of urine were voided, containing about 2.60 ounces of sugar; and on the 15th of December, 4 pints 8 ounces (which equal 72 ounces,) of urine were evacuated, containing little more than 2 ounces of sugar. We conclude, then, that while the urinous solution of sugar has been of pretty much the same strength, and with little variation, still, the amount of that solution has greatly varied.

4thly. And lastly, I would say, that the addition of a *little* amylaceous food to Hardy's diet appeared to produce but little unfavourale effect; there was, however, a slight increase of urine, and the pulse was more rapid; but the extreme comfort he derived from a small quantity of vegetable food more than counterbalanced the trivial consequences it produced.

I will now call your attention to Bowles's case, which, unfortunately, is not so favourable as Hardy's; it was always more confirmed, and the remedies which we used had not so marked an effect upon him; his case, moreover, was complicated with a phthisical tendency, which caused a rapid development of tubercles, of which he at last died. But though this case does not show as distinctly all the points which we have observed in the other, still, as far as it goes, it does not in any degree militate against the inferences deducible from the results of the treatment in Hardy's case.

Bowles entered the separate ward at the same time with Hardy, (Nov. 22nd,) and was subjected to nearly the same treatment, and always had the same diet.

When Bowles entered this ward he was very weak indeed; it fatigued him to walk about the room; all his symptoms, thirst, dryness of mouth, sweet taste, craving appetite, parched skin, great diuresis and constipated bowels, were urgent. Two days before his admission he weighed 111 pounds. He was ordered the same diet as Hardy, and, like him, took twenty-five grains of sulphate of zinc on the evening of this day. This emetic produced not the slightest effect upon the stomach; he did not vomit, neither was he nauseated in the least, but it occasioned a profuse diaphoresis during the night, and for the whole of the next day the skin was moister.

On the evening of the 24th he took another emetic, similar to the first; this, however, caused a good deal of nausea, but not vomiting; afterwards he passed a good night, but without sweating; the next day his skin was very slightly moist. The difficulty of exciting vomiting in diabetic subjects has been previously noticed by other observers; it is, perhaps, due to a diminished sensibility of the mucous membrane of the stomach.

On the 30th of this month he had a third emetic, consisting of Zinci Sulphatis, gr. xxx.; Pulveris Ipecacuanhæ, gr. xv. Soon after taking this he felt nausea, and in ten minutes he vomited about an ounce of mucus and water; after this he took some tea, and the nausea immediately left him; he sweated more during the subsequent night than on any previous occasion; he slept well, and was only disturbed once to pass water. The next day the skin was moister.

These matters which were vomited afforded us the only opportunity we had of ascertaining whether sugar might be found in the contents of the stomach; Mr. John Bowman analysed them for me, and he found them to contain diabetic sugar.

The change of treatment which Bowles underwent in this ward produced the same immediate effect upon his symptoms as we have noticed in Hardy. Take, for instance, the quantity of the urine:—

On November	22	192 ounces	were voided.
„	23	92	„ „
„	24	96	„ „
„	25	84	„ „
„	26	80	„ „
„	27	76	„ „

His other symptoms likewise improved; the skin was soft, and often moist; the mouth was also moist; the thirst less; the sweet taste vanished from the palate; the urine lost its diabetic odour; the saliva was abundant, and less acid; he was now seldom disturbed more than once during the night, and on the 29th not once, to micturate.

On the 1st of December, in compliance with his urgent request, I allowed him five ounces of bread, to be continued daily; the result was, that his urine, which amounted to ninety-six ounces on that day, rose to 116 ounces on the 2nd, 112 on the 3rd, 118 on the 4th, 124 on the 5th, and continued thus high till the 11th, on which day the bread was ordered to be discontinued. This produced a diminution to 88 ounces on the 11th, the same on the 12th, and 80 on the 13th of December. His pulse, which was 88 on the 1st, when he began to take bread, rose to 94 on the 2nd, and kept high for some days; his thirst also became greater; the saliva, however, was now alkaline. All the unfavourable symptoms improved when the bread was left off.

I would here point out to you a feature in this case, which was less manifest in Hardy's,—namely, that the per-centage of sugar in the urine seemed to bear somewhat of a direct relation to the other symptoms; that when they increased in severity, it increased in quantity; and, moreover, that the diet appeared to exercise a distinct influence on the amount of sugar.

These are some of Mr. Bowman's analyses of Bowles's urine:—

Date. 1848.	Amount of sugar* in the urine, *per cent.*
November 30	4.46
December 1	4.60
„ 6	6.46
„ 8	6.06
„ 14	3.00
„ 15	4.70
„ 17	3.50
„ 21	4.10
„ 24	4.10

Now you will observe in this table, that while our patient was in an improved state of health, which includes the dates of the 30th of November, and the 1st of December, on which the urine was analysed, then the per-centage of sugar was comparatively low; but after he took the five ounces of bread daily, the sugar increased to 6.46 on one day, and to 6.06 on another, thus rising two per cent. Again, the bread being discontinued on the 11th of December, and from that time forward, (as far as I have yet given you the analyses,) the quantity of sugar again diminished as low as before. Thus, you see the per-centage of sugar increased and decreased, *pari passu*, with the general symptoms, and the farinaceous character of the diet.

From the 11th to the 25th of December, the patient continued to progress very favourably. I will read to you the report from the case-book of the 20th, which describes his condition pretty much as it was during the whole of that interval.

"Feels stronger; can now walk some distance without feeling tired; has no sweet taste in the mouth; tongue clean and moist; bowels regular; the urine is still rendered of a dark colour by heat and Liquor Potassæ; sleeps well at night, but is generally disturbed *once* to make water; says he formerly had to pass water as many as eight or ten times during the night; skin moist; does not complain of thirst; pulse 80; urine 76 ounces; specific gravity, 1.031."

The urine varied, during this period, from 72 to 92 ounces *per diem*, its specific gravity averaging about 1.033.

On the 25th of December, I was obliged to allow Bowles some pudding, and he always had pudding, or something equivalent to it, every day afterwards. The result of this was, that the subsequent reports were unfavourable; I will read you that of the 28th as an example.

"Has passed a bad night, owing to severe headache and nausea; perspired very profusely; he did not take his tea last night, but his appetite is better this morning; tongue furred; skin hot and dry; does not feel thirsty; bowels not open; saliva acid; pulse 120."

I was obliged to allow Bowles some farinaceous food every day; he would no longer submit to the exclusive diet of animal food; so, on the 1st of January, I fixed the following for his daily diet, distributed through the day, as might best suit his own inclination.

Meat, 4 pounds.
Brown bread, 5 ounces.
Light pudding.
Carrara water, two bottles.
Water, 4 or 5 pints.

After this the general symptoms continued not so well; the pulse was never again below 90, and it was only once as low as that; 98 was its general frequency, and it once or twice reached 120.

The specific gravity of the urine now rose to 1.037, 1.040, and 1.042, and kept high always afterwards.

The per-centage quantity of the sugar also underwent a great increase. You will remember that on the 24th of December, when the patient was so much better, and whilst he was taking no bread or pudding, the sugar was 4.1 per cent. The following table shows how it had augmented during the month of January, when a different diet was being taken:—

* The amount of urea was the same as in Hardy's urine.

Date. 1848.	Amount of sugar in the urine, *per cent.*
Jan. 10	6.20
„ 18	6.12
„ 19	6.10
„ 24	6.31
„ 28	5.90
„ 31	5.86

It is remarkable that there does not appear to have been any increase in the amount of water passed by Bowles, notwithstanding the augmentation of his other symptoms, and the larger quantity of sugar which he generated. I am inclined to believe, however, (at least, after the 18th of January, when he was admitted into the common ward,) that he made away with some of his urine, after passing it when he went to the water closet.

There is one more item that I wish to notice, which I have not yet referred to, and that is, the patient's weight at different periods. The following are the records which have been kept on that subject:—

Date.	Weight.
Nov. 19th	111 pounds.
Dec. 23rd	112 „
„ 30th	115 „
Jan. 6th	112 „
„ 13th	109 „

These figures show that, at the early part of the treatment, when Bowles was getting so much better and stronger, and whilst he was using a diet almost destitute of vegetable matter, he gained in weight; but that after these measures had been laid aside he again lost weight. The only peculiar circumstance is, that the increase of weight went on after the 25th of December for a few days; but that soon changed, for a fortnight after, we find he had lost six pounds.

I had all along noticed that Bowles appeared more gravely affected than Hardy; but it was not till the 11th of January that the phthisical symptoms made their first appearance. On that day we noticed *cough*; this was at first slight, but the next day it was more severe, and troubled him greatly. He was then ordered some Vin. Ipecacuanhæ and Tinct. Hyoscyami; this appeared to benefit the cough, for the next day he was rather better; however, it soon became a good deal worse, and disturbed his rest at night; it was unaccompanied by expectoration.

On the 18th of January he was removed from the private ward into the Rose Ward; and from that time the cough and diabetic symptoms grew more severe. He now became very feverish; the pulse was 112 on the 18th, 116 on the 19th, and 120 on the 20th. Upon examination of the chest we were unable to discover any particular dulness on percussion, or deficiency of respiratory murmur, but we noticed a prolonged expiratory murmur on both sides.

During the last few days of January, Bowles got rapidly worse; he became much thinner and very weak; the tongue was furred, and the appetite much diminished; his cough became still more troublesome, especially at night, and his pulse kept up at 116 or 118; the thirst was greater than before.

On the 5th of February the report states, that, added to the prolonged expiratory murmur, there were observed slight dulness under both clavicles and the supra-spinal fossæ of both sides, roughness of breathing, and increased resonance of voice; the pulse this day was 122. He was ordered ammonia and wine.

From the 5th he rapidly sank. On the 6th he was very low and weak, felt a total disregard for all food and was more feverish; the pulse was 132; he lay in bed in a dozing state, groaning and muttering to himself in a sort of low delirium. He remained in the same condition during the 7th, but on the 8th he became still worse; he was then almost comatose; the breathing was hurried, respirations 48 in the minute; pulse 134, thready and very compressible; he passed his water unconsciously in bed; he could not be got to swallow any nourishment. On the morning of the 9th of February he died. The urine, during the last two days, contained fibrinous casts of the tubes of the kidney, a trace of albumen, and also a considerable quantity of fat. The comatose state which appeared just before Bowles died, arose, in all probability, from a poisoned state of the blood, the kidneys failing to some extent to remove the sugar or the urea, or perhaps both.

You will observe that it was about the middle of January that Bowles got so much worse; and I am informed that about that time, having been allowed one day to go out for a walk with Hardy, unacccompanied by the nurse or porter, he went to visit one of his relatives, and had what, to them, was a sumptuous repast of bread and butter, gin, beer, and apples. It would have been difficult for them to have chosen anything which could have been more improper for them; and I believe that this must have hastened Bowles's death, by producing an inflammatory state of the kidneys, which materially impaired their eliminative power.

We had a *post-mortem* examination of the body about twenty-four hours after death, and I will now give you the particulars of it, for it was one of unusual interest.

Post-mortem.—The body was much emaciated, and on cutting through the skin, very little subcutaneous adipose tissue was seen.

Head.—The brain appeared shrunk; there was an unusual quantity of cerebro-spinal fluid in the sub-arachnoid space, and there was much serum in the ventricles.

Thorax.—The serous cavities of the chest were dry; there were no pleuritic adhesions.

The *lungs* partially collapsed when the chest was opened; they were of a brighter red than natural, and were dotted all over with very numerous white spots. On cutting into the substance of the organ, they were found studded throughout with thousands of minute tubercles, about the size of a pin's head, and remarkably uniform in size; they were scarcely more plentiful in the upper than in the lower lobes of the lungs. These tubercles were white, opaque, and soft. When the lungs were cut into, they exhaled very powerfully the peculiar sweet odour so characteristic of the breath of diabetic patients, and some portions which were kept for three or four days out of spirit, exhaled this smell to the last. The lungs were everywhere pervious to air; crepitated under pressure, and floated in water. At the anterior part of the root of the right lung was a cyst, containing

about two drachms of pus, apparently formed by the suppuration of a lymphatic gland in this locality.

Abdomen.—The *stomach* was unnaturally large; it contained about two ounces of thick fluid, consisting principally of mucus. The mucous membrane had an unusual quantity of rugæ. Upon a microscopical examination of the membrane, I found the stomach tubes wonderfully well marked; the same was the case with the cells, and they contained an abundance of epithelium—in fact they were stuffed with epithelium. This highly developed state of the mucous membrane no doubt was connected with the activity of the digestive functions in the stomach.

I may here mention that I subjected some starch to artificial digestion, with the mucous membrane of the stomach, and found that it was converted into sugar. You are aware that the healthy gastric mucous membrane does not possess this power.

In the *duodenum* the tubes of Lieberkühn, and Brunner's glands were also found largely developed, and containing a similar abundance of epithelium.

The *colon*, throughout its entire length, was full of hardened fæces.

The *pancreas* was large, and exhibited the same exuberance of epithelium that I noticed in Brunner's glands and the tubes of the mucous membrane.

The *liver*, from the hosts of miliary tubercles with which it was studded, exhibited a more speckled aspect than the lungs; the tubercles were, some of them, smaller and some larger than those of the lungs, (they were all very small,) but they had the same physical characters, and their white colour contrasted remarkably with the dark parenchyma of the liver: their presence had caused no inflammation of the hepatic peritoneum. Under the microscope the cells of the liver were found to contain scarcely any fat or biliary matter. The *bile* which was found in the gall-bladder was analysed for me by Mr. Beale, and he found that it contained diabetic sugar.

The *spleen* contained a large number of minute tubercles, but presented no other peculiarity.

Being unable, from various engagements, to give my immediate attention to the *kidneys*, I requested Dr. Johnson to examine them carefully for me, and I have since seen portions of them with him. Dr. Johnson has kindly drawn up an account of the appearances, which I shall read to you.

"The kidneys were slightly above the natural size, vascular; in the cortical portion there were numerous small tubercles. On a microscopic examination the uriniferous tubes were found of a yellowish colour, from an abundance of granular matter and oil in the epithelial cells. The appearance of the renal cells contrasted remarkably with that of the liver cells, the latter being very transparent and colourless, and containing scarcely any biliary particles or oil; they had the appearance of being starved and emaciated, while the kidney cells were over-fed and plethoric.

"The urine passed about two days before death contained a small quantity of albumen, and some fine granular cylindrical moulds of the tubes. The albumen and the casts were probably connected with the tubercular deposit. The tubercles in the kidney had the same microscopic characters as those in the lung."

The existence of an unusual quantity of fat in the kidney has not only been shown microscopically, but also chemically, for Mr. Beale has made for me the following analysis:—

Kidney—(Bowles.)

Water - - -	76.800
Animal matter - -	18.792
Fatty matter - -	3.016
Fixed salts - -	1.392
	100.000

The amount of fat here found is triple that of a healthy kidney, for in health one per cent. is about the quantity it contains.

Not a trace of sugar could be discovered in the substance of the kidney.

I may here remark, that this is not the first case of diabetes in which I have found fat in the tubes of the kidney. The kidneys of a woman who died here last year of diabetes, contained fat in considerable quantity.

And now, in conclusion, I will call your attention to some inferences which the cases we have been considering suggest.

1. The first of these is, that the azotized dietetic plan of treatment is efficacious; that the patients were more benefited by it than by any other means; and that the admixture of a small quantity of vegetable food did not very materially interfere with its favourable operation.

2. The evidence furnished by these cases is opposed to Bouchardat's theory, that the sugar is wholly derived from amylaceous food, and is little, if anything, short of a refutation of it. Take, for instance, Hardy's case: when he was put into the solitary ward he was deprived of all amylaceous food, and yet he still continued passing from two to three ounces of sugar daily. But it may be said that this was furnished by the greens, which he then took; this, however, could not be the case, for they would hardly weigh as much as the sugar that was evacuated; but there was one period in which he did not even take greens; he took no vegetable food whatever, but lived entirely on meat, and that deprived of fat as much as possible. This period was from the 15th to the 24th of December; notwithstanding, however, this total exclusion of all vegetable matters from his diet for nine days, he evacuated in that time from twenty-five to thirty ounces of sugar, and his own bodily weight was all the while increasing. Whence, I would ask, could all this sugar have been obtained? The same circumstances occurred in Bowles's case, though not, perhaps, to so striking a degree.

3. The great increase of the power of the stomach is truly remarkable; these men found no difficulty in digesting four pounds of meat, besides several eggs, in one day, a task twice as great as any ordinary stomach could perform. The highly developed condition of the mucous membrane of the stomach was, no doubt, associated with this exalted power of digestion, and probably exists in all these cases.

4. The fact, that sugar could not be detected in the substance of the kidney, goes to show that it is not

there secreted, that it does not enter into any organic connection with the elements of the kidney, but merely percolates in solution through it; hence the disease of the kidney must be secondary. The sugar doubtless reaches the kidney in solution in the blood, and there acts upon that organ as a diuretic, passing possibly dissolved in the water that filters through the Malpighian bodies, and not being attracted from the blood through the walls of the tubes.

5. The comparative conditions of the epithelium of the liver and kidneys are very singular, and I am not aware that a similar observation has been previously made; it would tend to shew with what avidity all carbonaceous matters, fat as well as sugar, are directed to the kidney, in this disease. Most probably, to some extent, the fat of the liver goes, in common with fat from other parts of the body, to the formation of sugar; but this does not account for the deposition of fat in the epithelium of the kidneys.

Lastly, these cases justify the conclusion that this disease is essentially one of the primary organs of digestion, whereby all substances readily convertible into sugar are quickly so converted; and that sugar is not digested, but passes into the blood unchanged, whence it is rapidly eliminated by the kidneys. We must not forget that this was, in fact, the view taken of this disease by Dr. Rollo, an English physician, who was the first to suggest the plan of treatment, which all experience proves to be the most beneficial.

SHORT NOTES ON THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Phlegmone Testis.—This term implies inflammation of the testis, connected with gonorrhœa; but as the appearance of the swelling in this case does not differ from the swelling of the testis from any other cause, it is necessary to obtain a correct history of the disease. It is preceded by darting pains in one or both testicles; the scrotum is red and projecting, and pain is felt also in the loins; and sometimes before the local symptoms are developed, the constitutional disturbance is severe; the patient feels ill and faints, perhaps vomits, and has a frequent pulse, with general uneasiness.

Cases occur in which the constitution is remarkably low—in a state similar to that which precedes typhus fever—for a day or two prior to the accession of the inflammation, after which there are frequently the general symptoms of inflammation present, with pain in the lower intestines, and even delirium, particularly if the spermatic cord be involved as high as the abdominal ring.

The disease is situated in the body of the testicle, and extends to the tunica vaginalis and cord, producing, perhaps, a little hardness in the pubic region, but it does not primarily proceed down the cord to the testis.

When the disease proceeds unchecked by appropriate treatment, the tunica vaginalis testis contracts adhesions to the scrotum, and these often become the seat of abscess.

The testis seldom suppurates, but when it does, great attention is necessary lest the tubular portion protrude, or be pushed out in mistake for pus. This has occurred. These cases are tedious and difficult of cure.

It seldom happens that both testicles are simultaneously inflamed from gonorrhœal causes, although each may be affected in succession; and the left testicle, perhaps, is more frequently inflamed than the right.

A patient subject to rheumatism, who has had phlegmone testis, may, by exposure to cold, be severely attacked by rheumatic inflammation of the testicle, producing violent pain in the gland, extending down the thigh, and attended with spasmodic action of the external muscles of the thigh and leg.

Inflammation of the testicle most frequently attacks those who are recovering from gonorrhœa, where the discharge is very trifling, and where the symptoms are apparently favourable. It may be the result of taking cold, or may come on even without any evident cause.

It scarcely ever arises when the inflammatory symptoms are running high, and the discharge is profuse; but at the conclusion of these very cases, it is likely to take place, especially when they have been of long standing.

It has been said that phlegmone testis is frequently produced by the long use of irritating injections. This does not appear to be the fact; but it is to be admitted, that injudicous applications to the urethra, in the early stage of the disease, to check the discharge suddenly, will often produce inflammation of the testis.

The opinions of writers as to the *rationale* of phlegmone testis are various; some think that the inflammation is propagated down one of the vasa deferentia to the testicle, whilst others think the disease is caused by metastasis. Neither of these opinions is correct; the simple explanation is, that it is an inflammation of one part communicated to another, in close and natural relation to it.

Hence inflammation of the testis may be produced when the discharge from the urethra has ceased; and on the other hand, the return of the discharge may carry off the inflammation of the testicle.

The suppression of an accustomed discharge in one part of the body may produce a disease in another part. This is exemplfied in certain affections of the head, from the healing of an ulcer, or the suppression of an hæmorrhoidal flux.

Phlegmone testis is not the cure of gonorrhœa; it causes only a cessation or diminution of its symptoms,

* Continued from page 260.

which frequently return when the supervenient disease is removed.

Previously to the coming on of this affection of the testicle, there often appears to be a morbid sensibility of the gland, indicated by shooting pains and uneasiness; in this state, if proper means be used, the disease may probably be prevented.

This morbid sensibility of the testicle may, perhaps, be the remote cause of the inflammation; it will sometimes remain when the latter has been removed; indeed, the epididymis, or even the whole gland, may continue for a long time in this state, and is with much difficulty cured. In some instances the tenderness is so great, that the person cannot bear his clothes on, and is obliged to wear a bag truss to suspend the testis, and prevent the return of the inflammation.

In some of these cases the testicle may be examined by manipulation, without giving any pain at the time; but some time afterwards the uneasiness comes on.

Inflammation may be communicated to other parts as well as to the testicle—to Cooper's glands, the neck of the bladder, and to the perinæum, inducing a febrile disturbance of the system very much resembling low fever.

Dysuria Venerea sicca.—This is a morbid state of some part of the urethra, from impure intercourse, in which all the symptoms of urethral inflammation are present, except the discharge.

The patient is affected with ardor urinæ, expels the last drops of urine with great pain and spasmodic action; the orifice of the meatus urinarius externus is red, and the redness extends as far up the canal as usual. There is sometimes also chordee.

This form of the disease may exist in two states—1st, as an original complaint; and 2ndly, as the consequence of a common gonorrhœa. It comes on ten or fourteen days after infection when derived from that cause, and it is questionable whether it admits of a natural cure. When it is the result of gonorrhœa and has been produced by astringent injections, there will be great irritability and spasm; and when the discharge has been suppressed without any assignable cause, the uneasiness will often remain for a protracted period, probably by the irritation having been transferred to the corpus spongiosum.

Dysuria sicca may run through its whole course without the least discharge or even any particular redness of the meatus; but certainly a far greater number of cases will occur as merely preceding obstinate gonorrhœa.

Gonorrhœa in Females.—This disease in females is by no means so troublesome to manage, nor so severe in its symptoms, as in males; the inconveniences attending it are not more than would be felt for a slight inflammation of the nymphæ, or inner membrane of the vagina.

There is usually difficulty and pain in passing the urine, a redness and sense of fulness in the parts, and sometimes uneasiness in walking, or in sitting down on a hard seat.

In some cases there will be tumefaction of the prolabia, with pains of the groins, inside of the thighs, or lower parts of the abdomen; and in delicate women the stomach now and then becomes affected with flatulence and sickness; but these symptoms may very probably be produced by mental uneasiness, rather than from the disease.

When the parts are generally inflamed, all these symptoms are proportionately increased; the discharge becomes more profuse, and is often of a brownish or greenish colour, and sometimes tinged with blood; the urethra is involved, and the bladder becomes extremely irritable.

Anomalous Symptoms.—If the inflammation runs high, it will sometimes proceed to suppuration, and the abscess commonly bursts on the internal part of one of the labia, or into the vestibulum; abscess, however, is not a frequent occurrence in these cases, nor is it attended with any serious results.

An absorbent in the groin will sometimes enlarge, but it seldom suppurates; when it does take place, the formation of matter is attended with great pain.

There are two large laminæ situated on each side of the vagina, near the carunculæ myrtiformes, and leading to glands analagous to Cooper's glands in the male. These may inflame and discharge matter, or the inflammation may be extended to the glands themselves.

When this takes place, the tumour may increase to the size of an egg, filling up the os externum, and irritating the bladder and rectum; the tumefaction often extends to the labium pudendi, forming a red, shining, and transparent tumour.

The abscess will sometimes burst into the narrow ducts of these glands, producing a discharge from them as if it came from the vagina, and causing the patient to suppose that it came only from that membrane; when the abscess bursts through the parietes, the opening is generally small, and, if not enlarged, will become fistulous.

Inflammation of these glands may likewise proceed from various other sources; and it is extremely difficult to distinguish the discharge of gonorrhœa from the discharge from other causes of vaginal inflammation.

In leucorrhœa the colour of the discharge may be yellow, or green, or tinged with blood. Ardor urinæ is sometimes wanting in gonorrhœa, but it may occur in the more acrid discharge of fluor albus; this symptom, therefore, is no sure criterion. Inflammation or abscess of the labia or of the mucous glands may arise from other diseases as well as from gonorrhœa; and enlargement of the inguinal glands may also be produced by a very acrid discharge in leucorrhœa.

In this kind of inguinal swelling, it will always be better to form a judgment from the character the disease assumes, and from the history of the case, rather than from the character of the discharge.

In this place the question may be put:—Is gonorrhœa a local disease, or is it capable of infecting the system with lues venerea?

This question may be answered in the following manner:—A purulent discharge from the urethra may occur under various circumstances.

1st. A urethral puriform discharge may arise from excess of venery, intemperance, and hard riding; this species is not capable of communicating infection.

2nd. There is a purulent discharge from the urethra which arises from a morbiferous cause; this species will produce infection, but it will communicate a disease of its own kind, and nothing more. The system will not be contaminated, and no mercury will be required.

3rd. There is a form of gonorrhœa which will sometimes communicate lues, and many instances may be adduced to establish the fact; but certainly the far greater number of urethral purulent discharges must be considered as incapable of producing lues venerea.

[If this doctrine be correct, there is every reason to conclude that those cases of gonorrhœa which communicate lues arise from, or are complicated with, urethral chancre. But M. Ricord has established this as a fact, from extensive experience and close observation, in his important and valuable lectures now in the course of publication in the *Lancet*. He asserts, that in the course of sixteen years' practice he has discovered two urethral chancres on dissecting the canal after death; and that since January last he "has had no less than ten cases of blennorrhagia symptomatic of urethral chancre." It were vain to bring Hunter's two cases of gonorrhœa in criminals, whose urethræ he dissected after their execution, and in which he could find no breach of surface whatsoever, against the overwhelming testimony of M. Ricord. Urethral chancre, whether common gonorrhœa and lues be or be not derived from the same morbiferous cause, satisfactorily accounts for the production of lues from *some cases* of urethral purulent discharge.

There is nothing more extraordinary in the fact of an ulcer occuring on the mucous surface of the urethra, than that of an ulcer occurring on any other mucous surface.]

Gonorrhœa symptomatica.—This species of gonorrhœa takes its origin from gout, rheumatism, affections of the viscera, and also from stricture of the urethra. Gonorrhœa from gout is not at all uncommon; and when the discharge is suddenly checked, the pains of the joints will be greatly aggravated, and sometimes accompanied with erysipelatous inflammation of the superjacent integuments.

[At this time I have a case of rheumatic gonorrhœa in a middle-aged man in the Royal South Hants Infirmary. He had been under treatment a considerable time for chronic rheumatism, and the disease had nearly subsided under the use of the iodide of potassium, with alterative doses of blue pill, when the sclerotic membrane of the right eye became slightly inflamed, and soon afterwards a purulent discharge from the urethra began, which could not be traced to any other cause. It was treated with the balsam of copaiba, and it soon subsided. Purulent discharge from the vagina in children is not an unfrequent occurrence, and which, in a great majority of cases, cannot be traced to any contagious cause, and is, therefore, probably derived from some disorder of the functions of the viscera.]

Treatment of the first species of Gonorrhœa.—Gonorrhœa is considered as capable of natural cure, and this doctrine is not without foundation, as many instances of the disease, both in males and females, do become milder, and at length disappear, where no medicines are employed. A strict regimen is all that is required in most cases; many cases, however, will remain a long time, and retain the power of infection.

Notwithstanding this fact it cannot be known *a priori* which cases will admit of a natural cure, and which will proceed to aggravated symptoms and serious results.

By an appropriate mode of treatment this complaint may be mitigated, its duration shortened, and its consequences prevented; indeed there are cases of gonorrhœa which would never be cured by the unassisted efforts of the constitution, especially if they be of that species capable of communicating lues venerea.

In the cure of gonorrhœa there are two indications:—

1st. To destroy or correct the morbiferous poison.

2nd. To remove the symptoms, and thus put an entire stop to the disease.

With regard to the first, unfortunately there is no medicine that is capable of destroying the contagious and irritating properties of gonorrhœal matter; mercury, though a specific in lues, is not in gonorrhœa, since it is often found that when mercury has cured every symptom in lues, the discharge from the urethra remains. To fulfil the second indication, the antiphlogistic treatment must be strictly enjoined; the patient must abstain from venery; from all violent exercise, especially riding on horseback; from fermented and spirituous liquors, and all highly-seasoned food.

The parts are to be kept clean and cool, the bowels gently acted upon by mild aperients; violent purging aggravates, and will sometimes bring on the inflammatory symptoms. The patient should drink barley water, linseed decoction, and, in the summer months, rennet whey, and take small doses of nitre, with gum arabic, or tragacanth.

Some practitioners object to nitre upon the ground of its impregnating the urine with an addition of

neutral salts; but as no harm, at least, has resulted from its employment, and as something will reasonably be expected to be done, it will be right to give nitre, combined with the compound powder of tragacanth.

By this gentle treatment the first species of gonorrhœa will generally be cured in from five to eight weeks, although it would seem that little more is done than removing impediments to a natural cure.

(*To be continued.*)

FOREIGN BODY IMPACTED IN THE UTERUS.

By William Bush, Esq.

Senior Surgeon to the Bath Ear and Eye Infirmary, and to the Eastern Dispensary of Bath.

In the report of the Birmingham Pathological Society, recorded in the *Provincial Medical and Surgical Journal* of May 31st, I remarked a case by Dr. Fletcher, of a foreign body—a wooden skewer, an inch in length—having found its way into the rectum, the presence of which the patient could not explain. Having just previously met with a case of a foreign body thrust into the uterus, I am induced to make it public, believing it may be read with some interest by many of the profession.

On the 8th of May last I was requested to see professionally, a French lady, about 60 years of age, visiting this city. On enquiry, I found that she had been suffering from a leucorrhœal discharge for some years, arising, as she had been informed by her French medical attendant, from a tumour in the uterus, (which, however, on examination, I could not detect,) for which she was frequently in the habit of injecting water (or endeavouring to do so,) into the uterus, by means of a common metallic apparatus. Finding, however, that the tube of the instrument, in her opinion, was not sufficiently long to reach the womb, her ingenuity contrived to invaginate the metallic tube within a piece of an elastic one. On using, in the morning, this home-made apparatus, she found that it answered the purpose intended of entering the womb, but on removing the metallic instrument, she perceived, to her dismay, that the elastic tube (three inches in length,) was left behind. She immediately attempted to remove it, but her efforts to effect this only served to thrust it still further into the uterus, and under these circumstances I was sent for. On examination by the speculum vaginæ, I found that the os uteri and neck of the uterus were extraordinarily flaccid, and the former as wide open as if she had been recently confined. The tube was lying *within* and *directly across*, the dilated womb; little difficulty, however, was found, in extricating it from its perilous position.

Remarks.—This case is not given as affording any particular analogy to Dr. Fletcher's, still I cannot but consider it may throw some light upon the manner in which the piece of skewer found its way into the rectum, for it is scarcely possible to suppose a piece of wood of the size mentioned being swallowed without being known to the patient, either in the act of mastication or otherwise. The above case points out the injurious consequences of introducing injections into the womb; its flaccid and dilated condition and its discharge might be attributed to the remedy in which she was persisting. If injections are used, they should be used alone to the vagina; and if this case is a sample of the method adopted in France for leucorrhœal discharges, &c., no wonder that we hear of simple ulceration of the neck of the uterus being so common a disease there. My friend, Dr. Samuel Edwards, late of this city, has long believed from his experience, that mechanical violence is not unfrequently the cause of this disease in virgins, and those who have not borne children.

In conclusion, may not the frequent injections resorted to by the French throw some light on the fact, (which is, I believe, proverbial,) that women rarely have more than two or three children in that country? On mentioning the particulars of the above case to a medical friend of mine to-day, he stated, from what he had heard, that the last-named circumstance might be accounted for by their resorting to mechanical means to prevent conception from taking place. How far this may be the case, I will leave for others to determine.

POISONING BY FOWLER'S SOLUTION: ABORTION: MORTAL FAINTING.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

If you think that the annexed case of fatal poisoning by arsenic, besides being remarkable for the minute quantity taken, presents also some points of medico-legal interest, will you obligingly allow it a place in your Journal.

I am, Sir,
Your obedient servant,
HENRY T. CASTLE, M.D., (Edin.)

Leeds, June, 1848.

H. T———, a widow, being reported to have died suddenly from poison administered to her by a man with whom she cohabited, a legal examination was deemed requisite.

Fifty hours after death the body presented the following appearances:—Under parts of the body generally discoloured, from cadaveric extravasation; extremities of the fingers blue; abdomen tense. On opening the abdomen the stomach and intestines were seen distended with gas; inflammation of the former and of the small intestines was at once detected through their coats, and on exposing their mucous surface it was found to be general and intense. At the cardiac extremity of the stomach, and towards the lesser arch, several patches were seen of a deeper tint than the surrounding inflammation. Passing the colon the inflammation re-appeared in the rectum, which had apparently suffered in an equal degree with the stomach.

The uterus contained no fœtus, but was considerably enlarged; its internal surface was in colour modena-red, and copiously bedewed with mucus. The vagina was healthy. In dividing the ovaries, the scalpel had, in one, passed through the centre of, (what I believe to be,) a corpus luteum; this body is a perfectly empty cyst, the walls consist of two or more membranes, and the cavity will contain a good-sized pea. A slight mark, as of a cicatrix, is to be seen on the surface of the ovary, corresponding with the position of the cyst. The bladder was not examined. There was no appearance of recent disease in the chest or head. The heart was flabby, and contained a little fluid blood. The stomach, its scanty contents, and part of the liver, were sent to an able chemist, who found traces of arsenic in each.

From the imperfect evidence adduced at the inquest, it appeared that the deceased had taken, between Saturday and the following Wednesday, half an ounce of "Fowler's solution," in unknown doses. On the Friday following she grew worse, complained of general illness and fever, but of no sickness, purging, nor particular pain of the stomach. On Saturday she had frequent "fainting fits," but on Sunday appeared to be a little better, till, after eating a small quantity of pudding, and drinking some ginger beer, she had another fainting fit, and in a few minutes expired.

The chief points in this case appear to be:—

1. The small quantity of the poison that sufficed to prove fatal—perhaps the smallest on record, the (apparent) absence of vomiting and diarrhœa, and the unusual termination by mortal fainting.

2. The relation between the state of the intestinal mucous membrane and that of the uterus. Four months previous to her death the deceased had borne a child, which she had not suckled, and she was stated not to have been "unwell" since her delivery. There was also some reason to suspect that "herbs," to procure abortion, had been purchased for her only a fortnight before death. Assuming that emmenagogues had been taken, I incline to the opinion that the arsenic caused abortion.

Had the man who procured the "solution" been committed for manslaughter, which he narrowly escaped, the last question would have assumed a grave importance. In conclusion, I, as a young man, take the liberty to put to the elders of our profession the following query:—Can the date of the rupture of a Graafian vesicle, and escape of an ovum, be determined with any precision from the appearance of the corpus luteum? The ovary in question is very much at their service.

PROVINCIAL
Medical & Surgical Journal.

WEDNESDAY, JUNE 28, 1848.

We have elsewhere inserted the regulations adopted by the Council of Queen's College, Birmingham, for the foundation of a College of Literature and Arts. The measure is one of much importance to the fitting qualification of the young medical student for the proper understanding of the subjects which are to engage his attention, in the course of his professional education, and the enlightened founders of the Birmingham School of Medicine have done well to attach such an institution to their College.

The advantages resulting from the pursuits of literature, and from the formation of a taste for them in early youth, can scarcely be too highly estimated. The study of some branch of knowledge, whether of the purely literary, of arts, or of science, is an admirable means of disciplining the intellectual faculties, and strengthening the powers of the mind, and is indeed the main object of such studies for the youth of families of wealth, who are educated at our Colleges and Universities. But the early acquirement of knowledge, whether literary or scientific, which shall afford occupation for the leisure hours in after life, and give a taste for elegant and harmless, if not strictly utilitarian, pursuits, is scarcely secondary in importance. The tone of the mind is thus improved, and a healthy condition of the faculties encouraged and preserved, preventing their dissipation in a vicious excitement, (to which the man without purer tastes is peculiarly liable,) or in the listless inactivity of helpless idleness.

These, however, are merely general inducements to cultivation of the intellect, and of the several branches of knowledge, which must operate, more or less, with all. How much more important are such intellectual pursuits to those whose future avocations must derive, and indeed require, positive aid from them. The advantages of the mental training experienced in the study of languages and of the mathematical sciences, to the divine, the physician, or the lawyer, can scarcely be too highly estimated; and the actual knowledge acquired by them in various departments of these living arts, is most important in its results in their future intercourse with their fellow-men, and in the active pursuits of professional life. The strictness and certainty of mathematical induction are invaluable to the genuine physician, as enabling him to discriminate between the positive truths of his science on the one hand, and the fallacious reasonings with which it is encumbered on the other, at the same time that he assigns to probable, but not yet established, opinions and theories their just

importance. A knowledge of the ancient languages will often enable him to trace the vaunted discoveries of modern times in the records of almost forgotten ages, and may save investigation for many a weary hour, or direct his inquiries by many a useful hint into the right channel; while those who reflect how the mind is apt to impress its own preceptions and colouring on all that is foreign to itself, will at once see the advantages of searching out the meaning of an author, whether ancient or modern, in the original words in which such meaning was attempted to be conveyed.

This position is well illustrated in the eloquent Hunterian Oration, lately delivered before the Royal College of Surgeons, by Mr. Grainger—

"It is, perhaps," says the author, "one of the highest glories of HUNTER, that in proportion as the philisophic culture of organization has advanced, he who would attempt to record its progress, and especially to trace out the causes that have led to it, must ever and again return to him as to a beacon, which, in place of being obscured by waning years, has only shone forth in all its fulness and significance in these late and advanced times. * * * * We can at length perceive with the latest aids of sciences, that he neither was, nor could be, understood, in the time in which he lived. * * * * Amidst the innumerable additions that have from all quarters flowed in, there are scarcely any which do not find their place among the great principles announced by HUNTER; while not a few of the most profound discoveries, equally with the most minute, are but the repetitions of truths which he had long since proclaimed in a language *now* become clear and expressive.

Is it possible then, we would ask, to suppose that the conceptions of Hunter, not understood by his contemporaries of his own country, using the very language in which his ideas were attempted to be conveyed, could be rendered intelligible through the medium of translation into any other? The mere words might indeed be rendered, but the spirit which animated them could only be there where the mind of the translator was equal to its comprehension. And if it require all the light of modern discovery to clear up the so-called obscurities of the language in which his immortal works were written, how could any translation into a language foreign to his own be made the medium of conveying it to others. *Ex uno disce omnes.* The Greek and the German author, the ancient and the modern, must in like manner speak for themselves in their own words, and the physician who really wishes to understand either aright, should be familiar with the languages in which the thoughts are expressed. Let him then be fully prepared for all emergencies, by a liberal preliminary education, and whether in the cultivation of the powers of mind, or in the acquisition of knowledge which will most assuredly turn to future account, he cannot fail ultimately to receive his reward.

The Members of the Association will not fail to notice the alteration which has unavoidably taken place in the days of holding the Anniversary Meeting, as pointed out in the last page, and published in the advertising columns, of the present number.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

INFANT MORTALITY FROM BURNS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Since I forwarded to you the continuation of the abstract of the depositions before the coroner of Manchester, I have received from Dr. Barham, Physician to the Cornwall Infirmary, and President of the South Western Branch of the Provincial Medical and Surgical Association, a pamphlet on the burning of children. The title of it is "The Infant Martyrs," being the substance of Reports on the Burning of Children, communicated to the Royal Institution of Cornwall, August 11th, 1843." I have read this little pamphlet with great interest. It gives a very full statement of the frightful loss of life from burns, with valuable suggestions for the prevention of this accident. I strongly recommend the members of the Association to mention it to the clergy and benevolent of their respective neighbourhoods, as a useful and cheap tract for distribution among the labouring classes. The following quotations will be read with interest:—

"We may now enter on the consideration of the *causes* of this terrible havoc among our countrymen. There can be no question that the mode in which persons are burnt to death is, in a vast majority of cases, by their clothes catching fire. This is especially true as to children, and it is in them we are most interested in this inquiry, their protection being in a different sense and degree from that of adults, entrusted to the general care, and more likely also to be affected by extraneous interference, such as that to which it is in the power of our Societies to lend a helping hand. The proportion which the several periods of life bear to each other in the amount of mortality in each, from particular causes, is always an interesting and valuable object of research; but it is additionally important in the present inquiry, from its affording the means of inferring the mode of burning with great probability,

a point on which the *direct* evidence is rather defective. It has been very seldom stated in the registers of deaths how the burning occurred. In those for the Stafford District, Great Boughton Union, and Manchester, it is recorded that it arose from the clothes catching fire in 103 cases out of 160; and in the most accurate of these returns, that from South Staffordshire it is stated that of ninety-four who perished by burning, eighty-one were destroyed by their *clothes catching fire*, and of this number sixty-one were under ten of years of age. We shall now give the indirect evidence to the same effect, derived from the ages at which the burning has occurred among the three millions, in regard to whom we are in possession of precise information, and we shall at the same time perceive in how heavy a proportion this calamity has fallen on those who may fairly be considered as the infants of the community at large, entitled by their feebleness of body and mind to the guardianship of the public, and more especially so, inasmuch as they are commonly deprived of their natural protectors by the demand of the labours of the mothers made by that public. The total number of deaths by burning among the three millions in 1838 was 723; the ages at which they perished were as follows:—

Age.	Total Burnt.	Proportion for each year of age.
Under 1	5	5.
1 to 2	24	24.
2 to 3	69	69.
3 to 4	104	104.
4 to 5	117	117.
5 to 6	79	79.
6 to 8	105	52.5
8 to 10	38	19.
10 to 15	42	8.4
15 to 20	22	4.4
20 to 30	22	2.2
30 to 40	16	1.6
40 to 50	16	1.6
50 to 60	16	1.6
60 to 70	10	1.0
70 to 95	38	1.52.

"We here see that of 723 deaths by *burning*, 541 occurred under 10 years of age, 503 under 8, and 290 between the ages of 2 and 5. The general scale presents a regular gradation of mortality from this cause, ascending steadily from birth up to 5 years of age, then descending by progressive stages to 70. It tells us more clearly than words could do, who are the sufferers, and what the causes of their sacrifice. We have before us the infant less than a year old, necessarily protected by its own incapability of locomotion; in the course of the second year the power of getting at the fire is gradually attained, and is exhibited in the increased number of deaths. From 2 to 5 years of age the vivacity and curiosity of childhood are daily growing, together with the activity of movement, whilst the liability to falls is still great, the cautiousness of experience has been little acquired, and the lessons of others are slightly heeded. At this period of life both sexes are likewise nearly similarly attired in a light and combustive dress, readily drawn into the flames by the draught of the chimney. From this time the increase of knowledge, strength, care, and obedience, produces, slowly at first, afterwards with accelerated improvement, a steadily progressive diminution of the frequency of these fatal accidents; and the abandonment by the boy of the frock and the pinafore contributes materially to his safety.

"Few perhaps will have been prepared for the exhibition of such a host of sufferers, yet worse of such a multitude of little ones, who may demand our protection as their right, dying a death of agony from a cause which may be said to be, in its own nature, almost wholly within the scope of human prevention. But the death of these individuals is only one of the evils produced by this class of accident. We cannot accurately ascertain the number who escape with life, often to find it a burthen to themselves, and to constitute blemishes on the face of society,—objects at once of pity and disgust.

"A glance may be now given at the means most appropriate and available for the lessening of the frightful amount of destruction and suffering which has been shown to throw a cloud over the childhood of England, and in more than due proportion of our own county, (Cornwall.) The remedial measures which have suggested themselves are of a simple character, and are calculated either to prevent the near approach of children to the fire; to render their dress less inflammable, so that the risk of its catching fire may be lessened when they do get near it; and, thirdly, to cause the adoption of the most effectual methods of extinguishing the flames when an accident has actually happened. For effecting the first object, nothing is so much to be recommended as the use of substantial fire-guards, or, better still, of high fenders fastened to the sides of the hearth; these give the greatest amount of security at the cheapest rate, and they do away with the necessity of imposing much restraint upon the children; but in the lack of these, imprisonment of some sort is quite necessary where there is no trustworthy superintendence, and expedients for this purpose will present themselves too readily to require mention here. For the compassing of the second end, the rendering of the dress less inflammable, various suggestions have been offered. The cheapness of cotton goods, and their showiness, constitute attractions which make the substitution of the ancient woollen garments a matter of very difficult accomplishment; it is, however, the point to be aimed at, affording as it would do many other advantages to the poor besides comparative immunity for their offspring from the risk of the most horrible of deaths. It has been proposed, likewise, that the manufacturers should make their linen and cotton less combustible, by means of a chemical solution. This hint deserves consideration. A very simple expedient may be recommended for immediate adoption, as materially obviating the drawing of loose articles of dress into the fire by the draught,—it is the putting of a strong piece of tape at the bottom of the pinafore behind, securing the two sides together with sufficient

closeness to keep the dress in contact with the body without impeding freedom of movement. When the clothes are actually on fire, the first thing to be done is to obviate the mischief generally resulting to the head, from the natural tendency of flame to ascend; this is most readily attained by placing the sufferer in a horizontal position,—throwing him down; the fire will thus have little food in an upward direction, and it will be easily extinguished by rolling him on the floor, wrapping him in the carpet, or rug, or a blanket, sousing him with water, or applying a wet towel firmly to the burning clothes."

The foregoing extracts will give a fair idea of the contents of this useful little pamphlet. I was not aware till I received it, that the attention of the profession and public had been directed so ably to the great mortality from burns, and to the means of lessening it.

I forward to you a table of the cases of burns treated in the Royal Berkshire Hospital, from January, 1845, to January, 1848, together with a continuation of our abstracts of the depositions on burns, made at inquests held before the coroner of Manchester. These occupy a good deal of space in the Journal, but it appears to me that they are valuable in other respects than as explaining how the accidents happened. It will be seen that nearly all the cases are taken to the Infirmary. Hereafter I shall state what has been the treatment pursued in this institution at different periods, and compare it with that adopted in other institutions. The table will be of further interest as exhibiting, on the best evidence, the period when death usually takes place after burns.

I am, Sir, Your obedient servant,
SAMUEL CROMPTON.

71, Grosvenor Street, Manchester.

TABLE OF CASES OF BURNS TREATED IN THE ROYAL BERKSHIRE HOSPITAL.

(*From January, 1845, to January, 1848.*)

Communicated by F. A Bulley, Esq., Surgeon to the Hospital.

Date of Burn.	Sex.	Age.	Parts which were burnt.	Treatment.	Days Treated.	Results.
1845						
Jan. 7	F	4	Arm	Flour	13	Died Jan. 20, 1845
Dec. 5	F	3	Lower part of the face and both arms	Flour	2	Died Dec. 7, ..
1846						
Oct. 7	F	17	Arms, neck, and face	Tepid treacle and water ..	131	Discharged Feb. 16, 1847
Oct. 19	F	6	Right side of the body	Flour	8	Died Oct. 27, 1846
Dec. 4	F	10	Head, back, abdomen, and legs	Simple dressing	—	Died same day at two o'clock.
Dec. 8	F	9	Neck, &c. ..	Tepid treacle and water ..	104	Made out-patient March 23, 1847
Dec. 15	F	4	Face, arms, and shoulders	Simple dressing	8	Died Dec. 23, 1846
Dec. 31	F	6	Neck, &c. ..	Tepid treacle and water ..	82	Made out-patient March 23, 1847
1847						
Mar. 2	M	—	Leg	Tepid treacle and water ..	18	Cured, March 20, 1847.
Mar. 13	M	3	Face, neck, & breast	Flour	15	Died Mar. 28, 1847
Mar. 19	M	4	Abdomen ..	Simple dressing and Ung. Plumb.	73	Cured June 1, ..
April 3	F	10	Abdomen, arm, and thighs	Flour	28	Died May 1, ..
June 11	F	3½	Right side, arm, and leg	Simple dressing	5	Died June 15, ..
Aug. 13	F	14 mos.	Chest, face, and arm	Tepid treacle and water ..	31	Cured Sept. 14, 1847
Sept. 14	F	4	Arm and forehead	Ol. Lini, and Aqua Calcis	56	Cured Nov. 30, 1847
Dec. 2	M	10	Arms and chest ..	Tepid treacle and water ..	82	Relieved & made out-patient, Feb. 22, 1848
Dec. 27	M	31	Body and extremities	None	—	Died immediately

Continuation of Mr. Crompton's Digest of the Depositions on Burns and Scalds, made at Inquests held before James Chapman, Esq., Coroner for the Borough of Manchester.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death	Parts which were burnt.	How the accident occurred.	Remarks.
			1840				
96	M.	3 yrs.	Sept. 19	7 days	Body, both arms and face	Pinafore caught fire. Only another child of eight years in the house	Infirmary.
97	F.	11 yrs.	Sept. 26	3 days	Body, arms & face	Of weak intellect. Playing with lighted paper. Mother out	Infirmary.
98	M.	45 yrs.	Oct. 13	10½ hrs.	Arms, legs, & other parts	Under a steam-engine boiler, fastening a plate, when the boiling water escaped upon him. Wrapped in cotton immediately	Infirmary.
99	M.	3½ yrs.	Oct. 14	35 hrs.	Body, right arm, cheek, & ear	Lighting shavings	Infirmary, (out-patient.)
100	M.	6½ yrs.	Oct. 24	3½ hrs.	All over his body	Left alone. Pinafore caught fire in putting cinders on the fire	Infirmary.
101	F.	42 yrs.	Oct. 11	14 days	Legs and lower part of the body	Carrying boiling water in the dark; fell, and it flowed over her	Infirmary.
102	M.	8 mos.	Oct. 24	4 days	Lower part of back, belly & legs	Grandmother had him upon her knee, when he upset a saucepanful of boiling water by touching the handle	Infirmary, (out-patient.)
103	M.	1½ yr.	Nov. 5	35 hrs.	Chest and chin	Pulled the teapot, full of hot tea, upon himself	Flour immediately
104	M.	10 yrs.	Oct. 23	23 days	Thighs and lower part of body	Lucifer match "stuff" ignited in his pocket	———
105	F.	6 yrs.	Nov. 18	18 hrs.	Arms, thighs, and face	Alone. Lighted a stick "for a pipe"	Infirmary.
106	M.	5¼ yrs.	Nov. 25	3 days	Neck, face, arms, and hands	A blind boy. Mother in another room. Supposed that his pinafore caught fire	Infirmary, (out-patient.)
107	M.	3½ yrs.	Nov. 28	20 hrs.	Breast, face, hands, and arms	Left alone. Seen in flames by a person passing the cellar in which he lived	Infirmary, (out-patient.)
108	F.	4 yrs.	Nov. 27	24 hrs.	Neck, chest, face, & arms	Warming her feet, and reaching a cinder from the back of the fire. Mother out selling matches	Infirmary.
109	F.	7 yrs.	Dec. 3	5½ hrs.	All over the body	Stirring the fire. Parents out.	Infirmary.
110	F.	7½ yrs.	Dec. 4	10 hrs.	Ditto ..	Left with two younger children alone. Frock caught in reaching a comb off the chimney piece. Mother at factory	Infirmary.
111	F.	6¼ yrs.	Dec. 3	15 hours	Arms, breast, and face	Left with two younger children. Stirring the fire, when her clothes caught	Infirmary.
112	F.	6 yrs.	Dec. 8	26 hrs.	All over body, except legs and feet	Left alone for a few minutes	Infirmary.
113	F.	5¼ yrs.	Dec. 9	—	Upper parts of body, face and head	Lighting a paper, when her clothes caught. Cellar seemed to be full of smoke. She was found dead, and almost burnt to a cinder	———
114	F.	27 yrs.	Dec. 9	20 hrs.	All over except face & breast	While picking up nails from the floor, with her back to the fire, her clothes caught. She ran into the street, and it was with difficulty that she could be caught, and the fire extinguished	Infirmary.
115	F.	9 yrs.	Dec. 9	5 hours	Lower part of back, right arm, & thighs	Parents at factory. The deceased left in charge of three younger children. Clothes caught.	Infirmary.
116	F.	5 yrs.	Dec. 11	15 hrs.	All over body, except left arm	Clothes caught when she was standing on the fender. No mother. Father in another room	Infirmary.
117	M.	6½ yrs.	Dec. 14	26 hrs.	Face, arms, neck, & body	Mother at factory. Child crept out of bed in which there was a woman asleep, and was lighting a stick.	Infirmary.
118	M.	6 yrs.	Dec. 14	24 hrs.	Face, hands, neck, back, and shoulders	Clothes caught fire in lifting the kettle upon the fire. Parents out	Cotton applied immediately.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the Accident occurred.	Remarks.
119	M.	4 yrs.	Dec. 18	20 mins.	Burnt all over	Mother chatting with a neighbour about twenty yards from the house in which this child had been left alone	House full of smoke. Child perhaps partly suffocated.
120	M.	2½ yrs.	Dec. 18	6 hours.	Head, throat, and all over the body	Mother out. Left in charge of a little boy. Deceased was lighting paper	———
121	F.	4¼ ys.	Dec. 26	13 hrs.	Arms, face, & body	Pinafore caught fire. No one in the house except a little boy, aged seven years	Infirmary.
122	M.	1¼ yrs.	Dec. 14	11 days	Chest and left arm	Pulled over a basin of hot broth which was standing upon a table	Under Mr. Mann
123	F.	5½ yrs.	Dec. 28	22 hrs.	Belly, chest, nck. chin, & right leg & shoulder	Mother out. Father in bed. Clothes caught in lighting the fire	Linseed oil and lime water.
124	F.	6 yrs.	Dec. 30	19 hrs.	All over the body except legs	Left with a child, aged two years. Clothes caught fire in putting a pan on the fire	Infirmary.

Proceedings of Societies.

YORKSHIRE BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

At the Annual Meeting held at Leeds, on Thursday, June 8th, 1848, W. Hey, Esq., President, in the Chair, it was resolved to hold the next meeting at York, and that C. Williams, Esq., be the President-Elect. The Branch Council was re-appointed, and Mr. Husband re-elected Treasurer and Secretary.

After the ordinary business the following papers were read:—

The conclusion of a "Case of Fæcal Abscess," by Dr. Thurnam.

"On the Exploration of the Pelvic Viscera by the Rectum," by Mr. Teale.

"On the Local Effects of Chloroform on Animals," by Mr. Nunneley.

"On some Questions in Pathology," by Dr. Hudson.

LOCAL EFFECTS OF CHLOROFORM AND OTHER ANÆSTHETIC AGENTS.

Mr. Nunneley stated that for many months he had been engaged in making experimental researches on these agents, with a view to ascertain, as far as possible, the modus operandi, the doses which may be borne with impunity, and the different modes of application; as well as in case of an overdose, the best means to be adopted to counteract it. His experiments have not merely extended to the common anæsthetic agents employed, such as ether and chloroform, but he has been endeavouring to ascertain whether or not there may be some others, which may either be more safely administered, or may possess still greater advantages than the usual agents employed; which appeared to him to be by no means impossible, inasmuch as, so far as he could ascertain, the selection of those now employed, rather than others, seemed to have depended rather upon accident than deduction from experimental research, proving them to be in all respects the best. He stated that he believed it not improbable that it would ultimately be found, that all those preparations which have a *radical basis*, (in the language of modern chemistry,) such as acetic ether, bisulphuret of carbon, aldehyde, and many others of an analogous character, upon some of which he had made extensive experiments, would possess similar properties on the animal economy.

Mr. Nunneley was also prepared to state, *that chloroform appeared to be the most deleterious to life*, to require the greatest care in its administration, and that the boundary up to a fatal dose is by no means well marked—that of two animals, in apparently the same condition, the same dose being given in precisely the same way to both, the one will speedily die, while the other will bear it with impunity,—that from the effects observed, he has reason to think the ultimate effects are in some respects not dissimilar to those produced by prussic acid,—that to some animals, as for instance the newt, the frog, the toad, some fish, slugs, snails, and some insects, the effects are *more* rapidly fatal than prussic acid of Scheele's strength; and that even in higher animals, when under the influence of an incomplete dose, or recovering from the effects of a large dose of either chloroform or prussic acid, the phenomena are in many respects very similar,—and further, that the numerous *post-mortem* examinations which he he has made, fully corroborated this opinion. He stated that acetic ether, with which he had made numerous experiments, possesses very considerable anæsthetic powers,—that bisulphuret of carbon does also possess to some extent similar power, and so far as his experiments go, it is very important to add, that this power is of a safe character, the animal speedily recovering. But of all these remedies he believes that sulphuric ether will be found to be the safest and least noxious to life.

On these points Mr. Nunneley intends hereafter to lay his experiments, already very numerous and varied, before the profession. His chief object on the present occasion was to call the attention of the profession to experiments proving, as he thinks, the value and safety of a *new mode* of administering these agents, and to show that the action of all, or most of

these agents, might be produced *locally by local application*, the sensorium being unaffected, consciousness being retained, and the limbs not subjected to their influence being unaffected. He stated that either by *immersion* in a small quantity, or by the *vapour applied* merely for a limited period, a limb may be rendered *perfectly motionless and senseless*, and what may be an additional advantage *fixed in any desired position*. He had immersed his finger in these fluids for about half an hour or an hour, and at the end of this period the finger was nearly powerless and insensible, and that it was forty-eight hours before the effects entirely disappeared, a sensation of heat and discomfort extending along the tract of the nerves to the axilla. Before operating on a difficult case for artificial pupil, he had applied for twenty minutes a small quantity of the vapour of chloroform to the eye by means of a small jar which accurately fitted the orbit, with the effect of rendering the parts nearly insensible. The first effect of these agents when locally applied is to produce redness, heat, and smarting, which subside, followed by swelling and redness of the integuments, which remain for some time. Mr. Nunneley stated that he could completely paralyse any limb of frogs or toads by immersion or exposure to the vapour, in about five minutes or less; and he mentioned, as a curious fact, that if the exposure to the influence were continued longer than was sufficient to produce a local effect, this influence extended to the corresponding limb of the other side: thus, for instance, if one hind leg became *too much* influenced, the other hind leg partook of the same effect—if the fore leg were too much affected, then the other fore leg became so likewise, and subsequently, the whole body—a result which Mr. Nunneley mentioned as strongly corroborative of his experiments with prussic acid, as detailed in the last volume of the "Provincial Transantions," and strongly supporting the opinions of Dr. Marshall Hall on "reflex action." By this new mode of application to the hind legs of rabbits he had also been enabled to amputate the toes without the least indication of feeling.

These views were illustrated by a series of interesting experiments on frogs and toads, in which, after immersion for a few minutes, the limbs became insensible, and were amputated in repeated portions without any symptoms of pain whatever.

[We are indebted to Mr. Nunneley for the foregoing account, (taken from the forthcoming volume of Mr. Braithwaite's "Retrospect,") and also for a letter on the mode of performing the experiments on animals, from which the following is an extract:]—

"For showing the local effect, nothing is better adapted than the living leg or legs of a frog. All that is necessary is to put a few drops of the agent we wish to ascertain the effect of, into an ounce, ounce and a half, or two ounce vial, according to the size of the frog, having such a mouth as to receive the limb, and just fit round the upper part of the thigh, without, however, compressing it, and in order to avoid the vapour escaping, then passing round a few folds of a strip of linen or other bandage. If it is wished to see the effects of the vapour, the bottle should be sufficiently long not to allow the toes to touch the fluid, and the bottle should be kept quite still in an upright position; but if it be wished to apply the fluid itself, then the toes should touch the bottom, or the bottle be from time to time placed on the side in order to allow the fluid to pass over the limb, by which proceeding but little of the substance is required. At first the creature struggles, the fluid evidently acting as a stimulant, and at that time a little effort is required to keep it in position; presently it will remain *in situ*, for the immersed member becomes still and motionless. In from two to five minutes the full effect is produced, and the limb is perfectly insensible. If one leg be kept in too long, the other hind leg is affected, or the whole body is brought under the influence of it; when the experiment is less satisfactory, and the animal is liable to die. After the application the limb remains for some time swollen, and the colour of the skin is altered.

"In the case of other animals, the time necessary for immersion, before complete insensibility takes place, will vary with circumstances, as to the temperature, but more especially the aptitude of the integument for absorption, and the nature of its covering. Thus, if the skin be hard, the epidermis thick, with the hair stiff and long, then a considerable period will be required. In the case of a rabbit, the other night, after an hour's immersion, I cut off the whole of the toes in succession, and then amputated the entire foot, cutting through the metatarsal, and then the tarsal bone, the creature lying upon my knees in the most quiescent state possible, there not being the least disturbance of the countenance during these operations. But the moment either of the other limbs were touched, and also what is of great interest, the *same limb above where the chloroform had reached*, it at once started up, with every indication of pain, shewing how precisely the effect may be limited. The same operations I have also performed upon a kitten, and upon two dogs, (old;) these were, as might be expected, after a similar length of immersion, though considerable diminution of sensibility was produced, not rendered entirely devoid of feeling.

"I may mention that to-day, (June 22nd,) I have operated upon a staphylatomatous eye, in a man from a distance, after the local action of chloroform, when I removed the entire cornea with a small portion of sclerotic coat and iris, with hardly any infliction of pain; and what is singular, so completely were the muscles of the globe affected, that for some time afterwards the remains of the eye did not collapse, although their attachments were not cut through. The fluid had been applied longer than necessary, or I had intended, as, after having given directions for it to be applied until my arrival, I was detained away longer than I had expected.

"I have been making experiments upon two new agents, both of which I find to possess considerable anæsthetic property, and one of which I believe will prove to be superior in every respect to chloroform."

The communications elicited considerable discussion, and the Members who contributed them, received the thanks of the Meeting, and were requested to publish them in the Journal.

BIRMINGHAM PATHOLOGICAL SOCIETY.

May 4th, 1848.

Dr. FLETCHER in the Chair.

HEMIPLEGIA: SOFTENING OF THE BRAIN: DISEASED AORTIC VALVES.

Dr. Russell exhibited a heart, with bony spiculæ about the aortic valves, from a patient who had died hemiplegic, in whom the right hemisphere of the brain above the floor of the ventricle was destroyed.

F. R———, aged 67, shoe-maker, has been occasionally rather intemperate lately; some years ago he drank a good deal. Previous health good. I found him in bed, hemiplegic on his left side. His illness had been rather gradual in its approach; before its commencement he had been complaining of feeling unusually tired and weary, and of being unable to go to fetch his work. On December 8th his wife being ill, he went for his work, a distance of one mile and a half: he had great difficulty in getting home, and said he felt sure that he had been for the last time. The next three days he kept his bed, and seemed to be getting weaker in his left side. On the 4th day, when attempting to get out of bed, he found he could not stand; since that time he has been confined to bed entirely. I saw him December 30th, 1847. His state was as follows:—No power over his left arm; partial power over his left leg and thigh; mouth a little drawn to the left side; left cheek somewhat fallen in, and vibrated when he spoke; tongue deviated slightly to the left; sensation of left side somewhat blunted; senses entire; speech less distinct than natural for the preceding day or two; pupils natural; perfect control over the sphincters; some pain in the head, but relieved by a blister; tongue rather furred; bowels required aperient medicine; urine loaded with lithates; a loud systolic bellows-sound over the base of the heart, and along the aorta, carotids, and subclavians. His case was protracted till April 15th, 1848. For the first fortnight after I saw him he seemed to be gaining power over the leg, and to be getting stronger, but he soon fell off again. He preserved a remarkably good appetite through his illness, but grew weaker slowly. Early in January he began to have delirium by night, and his sleep was greatly disturbed thereby; about that time he began also to suffer much pain in his extremities, particularly in the left arm, when the limb was handled. He then complained of frontal headache, though the pain in the head was never a prominent symptom. The pains in the limbs became more severe, and distressed him greatly, so that he was entirely dependent on morphine, in one grain and a half doses, for relief; the pain was seldom referred to any one part, though the right leg was often most complained of. The delirium, soon after its appearance, came on occasionally in the course of the day, when he imagined himself at his work, but he was easily induced to talk rationally; partly from this cause, but more from the great pain excited by handling or moving him, he resisted the necessary changes of linen, and towards the end of his life a large slough added to his sufferings. After the beginning of February, his urine was occasionally passed involuntarily, during two or three days at a time, and occasionally, also, his stools; his bowels required the constant administration of castor oil. His pupils continued natural; his tongue deviated, as at my first report; the degree of power in the left side underwent little change, and the right side continued under his control. In the course of the last month of his illness, I made the following reports of the state of the paralysed limbs:—The lower extremities were equally emaciated; the left foot and ankle somewhat œdematous; the muscles of the left leg act slightly when the sole of the foot is irritated; the left ankle is in a state of constant extreme extension; the left hand half closed, and the left elbow half bent; the fingers and forearm resisted extension; he cannot always localize the sensation excited by touching the left side, but the skin is very sensitive on contact with anything. Died quickly April 15th, having enjoyed his tea two hours before death. The treatment throughout consisted entirely of tonics; afterwards of stimulants, of sedatives, and of purgatives, as required.

Post-mortem sixty hours after death. Body not particularly emaciated. *Head*:—On removing the dura mater, the right hemisphere was observed to be remarkably yielding, and when the brain was placed on the table, the right hemisphere seemed unable to support the weight of the left, and a quantity of soft pultaceous matter issued from its anterior lobe. Surface of the brain healthy; left hemisphere firm and healthy. On cutting into the right hemisphere, it was found to consist of a large irregular cavity, covered in by a thin layer of cerebral matter, and having for its floor the parts which constitute the floor of the lateral ventricle. The wall of this cavity above was formed of cerebral matter, about half an inch in thickness, and tolerably healthy in its appearance; the cavity contained a brownish pultaceous matter, which flowed out when it was opened; the floor of the cavity was covered with a layer of similar matter, but of somewhat firmer consistence, and apparently mixed with blood. The destructive process had not extended into the parts forming the floor of the lateral ventricle, and the base of the brain was healthy. The arteries at the base of the brain were also healthy. The heart was healthy, excepting some bony spiculæ in the aortic valves, and in the muscular structure near the orifice of the aorta. The aorta healthy. The liver was of a deep yellow colour, its cut surface very smooth, and the acini less distinct than usual; its texture very friable. The cells of the organ were enormously gorged with oil-globules. A small proportion of the cells of the right kidney also contained some oil-globules. The left kidney was not examined by the microscope.

HYPERTROPHY OF THE HEART, WITH DILATATION.

Dr. Mackay presented the heart, with the left ventricle hypertrophied and dilated, of a child who had died suddenly with pulmonary symptoms.

The heart was taken from the body of a girl fourteen months old; it is as large as it usually is in a child three or four years of age. The left ventricle is disproportionately capacious, but in other respects the organ is in a state of enlargement simply, without any mark of disease in the valves or elsewhere. Nothing unusual could be detected in the aorta, as far as its arch, or in its valves. The heart filled the left side of the chest so as to conceal the lung, and extended beyond the centre of the sternum, towards the right side, over which space percussion elicited a dull sound.

Nothing had occurred during the life of the child calculated to excite suspicion of this abnormal condition of the heart. It was during its brief life a healthy though rather a delicate looking child. Upon the day preceding its death it seemed indisposed, but so slightly as to prevent any apprehension regarding it. On the following morning, about nine a.m., it was seen by the surgeon of the family, who found it breathing rather hurriedly and coughing a little, with slight sonorous rales on both sides of the chest. The child sat upon its mother's knee and really seemed to have little the matter with it. In this state it continued till its death, which took place about twelve at noon, suddenly, without any change in its appearance or state. Both lungs were somewhat congested; the abdominal viscera were healthy.

FUNGOID TUMOUR OF THE ARM.

Mr. W. H. Partridge presented a tumour of a fungoid character, removed from the right arm.

A gentleman, aged 60, of good constitution, florid complexion, and temperate in his habits, but has occasional gout in the foot, in getting on the top of a coach, while standing on the wheel, by a sudden movement of the vehicle, lost his footing, and remained suspended by the right arm and hand, by which he held the rail. The arm was painful and weak for some time, and at the end of a month he perceived a small tumour at the insertion of the deltoid. This gradually increased to the size of a hen's egg, when it was proposed to remove it by operation. At this time there were two openings in it, from which an amber-coloured glutinous fluid flowed, and by the introduction of a probe, and moving it about, a large quantity of cellular membrane, filled with the same kind of fluid could be pressed out. The tumour increased, and seemed to have no firm attachment, but the fear of the operation prevented his having it removed by the knife. He then placed himself under the care of a woman near Dudley, and at the end of two months returned, with the tumour increased to the size of a melon, and with a raw bleeding surface, from the use of caustic applications. He now consented to its removal, which was accordingly done. The wound healed, and remained well for two years, when at the upper part of the cicatrix a new tumour began to form, increasing rapidly, having, in little more than two months, acquired the magnitude of a large orange; and the integuments having given way at the apex, a bleeding fungus shot forth. It was removed about a fortnight ago, and is what I now present to the inspection of the society. It had to be dissected from the surface of the deltoid, to which it was firmly attached by condensed cellular membrane, resembling a portion of a cyst or fascia. The wound is healing kindly, but the disease will probably return at no very distant period.

EMPYEMA.

Dr. Fletcher exhibited some fluid removed from the chest of a patient, by the operation of empyema.

Dr. Fletcher presented this fluid on the present occasion, as its characters would not be preserved if he waited for the termination of the case; he promised a full report of the case on a future occasion. The upper portion of the liquid was nearly clear, but the lower half contained a copious half-membranous deposit, of a whitish colour, most probably the coagulated fibrin contained in the fluid; it partially floated in the liquid, was semitransparent, and appeared of the consistence of a soft fine membrane. The quantity of fluid drawn off from the chest, amounted to more than a gallon. The operation afforded great relief.

ANEURISM OF THE THORACIC AORTA.

Dr. Fletcher presented a large aneurism of the thoracic aorta, just below the arch. The history of the case had been drawn up by Mr. Blount.

Noah Butler, aged 65, has been a lock-filer and a screw-turner, but for the last five years a milkman, carrying six or seven gallons of milk for two miles, every night and morning. His illness came on in June, 1845, with pain down the spine; numbness over the left side of the body, and dyspnœa, which gradually become so severe that he could not assume a recumbent posture, were the symptoms. Physical signs of aneurism we may fairly suppose were not present, as several intelligent practitioners, under whose care he had been during this time, failed to notice them.

April 20th, 1846. I saw him first, and detected a pulsating tumour, which neither he nor his wife had before noticed. It was situated between the spine and left scapula, was covered merely by integument of a natural colour, the ribs having been removed by absorption, and was about the size of half a lemon. Dr. Fletcher saw him about this time, and noticed almost complete absence of respiratory sound in the left lung, but no arterial sound was audible in the tumour. It gradually increased in size, rising higher towards the superior angle of the scapula, with great dyspnœa, cough, and expectoration, often coloured; great pain in the side, back and loins; pulse generally about 112; emaciation increasing. The integument covering it became red, and progressively deepened in colour to purple, but did not give way.

June 24th, 25th, and 28th. Hæmoptysis to nearly a pint each day, which ceased, but returned again during the first week in September. He died suddenly, September 7th, 1846, having expectorated an immense quantity of blood.

Dr. Fletcher was not present at the *post-mortem* examination, and did not receive the specimen until some time afterwards. The thoracic aorta was dilated into a very large aneurism, commencing just below the termination of the arch: it did not contain any fibrinous deposit. Portions of carious ribs were attached to the wall of the sac. The aneurism had burst into the left bronchus; there were, besides, communications with some of the smaller bronchi, which seem to have been plugged up by fibrine. The left lung was consolidated.

Mr. W. H. Partridge presented a pendulous tumour, or large fleshy wart, removed from the loins of an aged female.

Foreign Department.

CLINICAL MEDICINE AND SURGERY IN THE CONTINENTAL HOSPITALS.

Fractional Doses of Mercury.—Dr. Fleming, in the *Monthly Journal*, (June,) mentions that M. Trousseau gives calomel in repeated small doses, as 1-20th of a

grain every hour, which, when necessary, he continues till the gums are touched. This event sometimes occurs at the end of the first day, or when one grain has been taken, and rarely is postponed beyond the third. The advantages of this method are stated to be—1st. The system is brought under mercurial influence as rapidly as by any other mode of exhibition. 2nd. The ptyalism is readily controllable.

In the treatment of puerperal fever, MM. Trousseau and Velpeau insist strongly on the necessity of rapidly inducing mercurialism. With this view, large doses of calomel were administered internally, and, at the same time, mercurial ointment, to the extent often of a pound daily, was rubbed into the skin. Although they had reason to believe that this heroic medication frequently saved the lives of their patients, they had often to deplore the baneful effects of excessive mercurial action,—viz., gangrenous inflammation of the vulva, serious lesions of the mouth, &c. For the last two years, Trousseau has adopted the method *à doses réfractées* in the treatment of this disease, and is convinced that he thus obtains all the good, and completely avoids the evil effects of the remedy.

In *chronic* diseases, or where it is desired to bring on mercurialism gradually, the same dose (1-24th of a grain) may be given every third or fourth hour, when tenderness of the gums will probably not appear before the fifth or eighth day.

In the treatment of constitutional syphilis, lupus, &c., Hebra of Vienna prescribes corrosive sublimate in a similar manner. One grain of the bichloride is dissolved in twelve ounces of water, and of this solution half an ounce is taken thrice daily. In the cases which Dr. Fleming observed of this mode of treatment, salivation presented itself rarely before the eighth day, more commonly about the eleventh or twelfth day.

The merit of having first directed attention to this mode of administering calomel is due to Dr. Law, of Dublin, whose paper on the subject, which appeared in 1839, seems not to have attracted much attention in this country. Dr. Douglas Maclagan has had occasion more than once to verify the statements of Dr. Law.

Dr. Fleming has himself, during the last six months, adopted the practice in about twelve instances with success, in so far as regards the physiological action of the drug. He places in connection with the above, the views of Mialhe on the changes which calomel undergoes in the stomach previous to absorption, and which certainly enable us to understand the *modus operandi* of Law's method of exhibiting calomel.—(*Traité de l'Art de Formuler*, p. 5.) It has long been known, that, placed in contact with a solution of an alkaline chloride, as common salt, accompanied or not with muriatic or other acids, calomel undergoes a partial transformation into the bichloride and metallic mercury, and as calomel itself is insoluble, and consequently incapable of absorption, we must attribute its remote physiological action to this change. The interesting experiments of Mialhe show that the quantity of corrosive sublimate formed, bears no proportion to the amount of calomel employed, but is in exact relation to the quantity of alkaline chloride present in the solution. Thus, the quantity of alkaline chloride present in the stomach at any one time, being generally not more than sufficient to convert a very small quantity of calomel into bichloride, it is immaterial, in so far as absorption is concerned, whether one grain or one drachm of calomel is administered, as in either case the quantity of bichloride formed is the same. The frequent administration of small doses, as in Law's method, has the advantage of exposing the calomel to the action of a large quantity of the gastro-intestinal fluids.

According to this view, the exhibition of common salt with the calomel ought to increase its activity in a marked degree, and perhaps the cases of so-called idiosyncrasy, where a small quantity of chloride has given rise to severe salivation, may find in this circumstance a rational explanation. On the other hand, the changes in chemical composition which the gastro-intestinal fluids undergo during disease, will modify powerfully the action of calomel.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS.

The revolution appears to have materially interfered with the sittings of the scientific academies of Paris, for the communications have of late been few and far between. We have very little to communicate of value during the month just expired, but the following comprise the most important.

M. Capuron presented a new instrument for craniotomy, but a description of it without illustrations would be useless.

M. Mialhe read an "Essay on Purgatives." He believes that all medicines of this class act through chemical decomposition. He divides them into general and special purgatives, the first acting upon the whole length of the intestinal tube, the other upon a limited portion only.

M. Durand Fardel, reported on a memoir entitled, "On Cerebral Congestion, in its relations to Hæmorrhage and Softening." But this memoir is also destitute of interest.

The Academy of Sciences has not received a single communication since the last report.

QUEEN'S COLLEGE, BIRMINGHAM.

In the Journal for March 23rd, we published the first Report of the Sub-Committee appointed to draw up rules for the establishment and government of a "Department of General Literature," we now submit to our professional friends the second Report adopted at a highly influential meeting of the Council held on the 3rd inst., at which the Right Honourable the Principal, Lord Lyttelton, presided.

Your Committee, in obedience to the wishes of the Council, having given their best attention to the important subject referred to them, beg to offer the following suggestions:—

1. That the College be called the "Department of General Literature."

2. That the Collegiate system in this department be the same as in the medical department.

3. That the houses in the Crescent, numbered 7 and 8, be the site of the said department.

4. That preparations be made for opening the said department for the admission of students on the first of October next.

5. That the Lord Bishop of the Diocese be the visitor.

6. That the ex-officio members of the Council of Queen's College, with the Warden, constitute a Senatus Academicus.

7. That the said ex-officio members do appoint the Warden, and the said Senatus do appoint the Classical and Mathematical tutors.

8. That the Senatus do appoint, under such regulations as they shall think advisable, the "Fellows."

9. That until the appointment of such Fellows the said Senatus do transact all the general business of the department.

10. That not less than five members of the Senatus, including the Warden, do form a quorum.

11. That after the appointment of the Fellows, any number of them, not exceeding twelve, shall be elected for a Board of Management by the Senatus.

12. That such Board of Management be called "The Council of the Department of General Literature."

13. That an annual meeting of such Council be held on the last Wednesday in August every year.

14. That the Warden be a priest of the Church of England, and the Tutors priests or deacons and graduates of Cambridge or Oxford, or other chartered University.

15. That the Classical Tutor be the Senior Tutor.

16. That such Senior Tutor be responsible for the discipline of the College subject to the general supervision of the Warden.

17. That in the absence of the Senior Tutor, the Mathematical Tutor do take his place, and perform his duties.

18. That all the Tutors be expected to take their meals in the Hall with the students, the Senior Tutor occupying the head of the table.

19. That the Warden do fill the same position in the College of General Literature, as the heads of houses in Cambridge and Oxford do with regard to their respective Colleges, excepting that the lectures on the subjects below specified be delivered by him, or more especially under his direction.

20. That the students in the "Department of General Literature" do attend Queen's College chapel twice every Sunday.

21. That the Warden, Tutors, and students, do wear their gowns in the Hall, in chapel, and at lectures.

22. That each student have a room to himself.

23. That they have a common room.

24. That all meals be taken in Hall, except in cases of illness with an *ægrotat*, or of absence with leave.

25. That the vacations be for three months every year,—two months in the summer, (August and September,) two weeks at Christmas, and two weeks at Easter.

26. That the porter do close the College gates every night at ten o'clock, and that all students be expected to be within gates at that hour.

27. Students entering College at a later period of the night to be reported to the Tutor by the porter, who shall have a book provided for that purpose.

28. That for neglect or misconduct on the part of any student, the Senior Tutor shall have the power of imposing restraint within the College walls, and literary exercises called impositions.

29. That the Warden, in conjunction with the Classical and Mathematical Tutors, shall have the power of rustication for any period not exceeding two months.

30. That all cases, which in the opinion of the Warden and Tutors subject a student to dismissal or expulsion, be referred to the Council, who are to investigate and decide thereupon.

31. That the Senior Tutor have the management of the domestic arrangements of the College.

32. That the finance department be under the supervision of the Warden, who is every three months to lay a statement before the Council, and that the Council do every year appoint an Auditor.

33. That a monthly meeting be held on the first Tuesday in every month.

34. That the College be self-supporting, except as far as it may be aided by individuals endowing Fellowships, Scholarships, and Professorships, establishing prizes, and making donations of books.

35. That an examination on all the subjects of the Tutors' lectures be held at the close of every term.

36. That certificates of merit be awarded after each examination, and that any such annual prizes as the friends of the Institution may offer, be decided at the termination of the midsummer examination.

37. That students be expected to matriculate at the University at the end of their first year, if they have not done so previously, and that they be expected to take their degrees of B.A., or B.C.L., or such other degrees as their standing in the University will permit, at the end of the third year.

38. That such students as have been regular in their attendance at chapel and lectures, and have conducted themselves satisfactorily in *statu pupillari*, be eligible to be appointed Fellows, on their attaining to the degree of B.A or B.C.L.

39. That a commemoration day be held once every year, in honour of the founder, Mr. William Sands Cox, that the Members of the Council and the Fellows and their respective friends be invited to attend.

PLAN OF STUDY.

1. That the *curriculum* of study do extend over three years.

2. That the students of each year have distinct courses of lectures.

3. That the subjects of study be Greek, Latin, Mathematics, Logic, the Modern Languages, History, Civil Engineering, Natural, Political, and Moral Philosophy, and more especially Christian Ethics, and the Doctrines of the Church of England.

4. That each student do attend four lectures every day,—namely for one hour in the morning a lecture in Greek, for another hour a lecture in Mathematics, and for one hour in the afternoon a lecture in Latin, and another hour a lecture on History, Logic, one of the above described branches of Philosophy or Civil Engineering.

5. That the subjects selected have particular reference

to the requirements for the examinations of the University of London.

6. That the Tutors do confer with the Warden at the commencement of every year, as to such selections, and that no deviations be afterwards made therefrom, without his express permission.

7. That the Warden be responsible for the instruction in Christian Ethics, Church History, and the Doctrines of the Church of England.

8. That Drawing, French, and German, be expected to be learnt during the two years when the Students are in the Junior Department; but if they have not then completed such courses of study, or require for any purpose, during their residence in the College, instruction in the modern languages, the same to be supplied at the rate of three guineas each course per annum.

Scale of Fees.

That the annual College expenses be according to the following scale:—

Furnished rooms and board, with coals, candles, &c. &c.	50	0	0
Lectures in Divinity, Classics, Mathematics, Civil Engineering, History, Philosophy, and Logic	20	0	0
College Fees	5	0	0
	£75	0	0

2. That the sum of twenty-five pounds be paid at the commencement of each term.

James Thomas Law, Chancellor of the Diocese of Lichfield, Vice-Principal.
John Birt Davies, M.D.
William Sands Cox, F.R.S.

The following report was adopted to prevent students incurring debt, both in the "Medical Department," as well as in the "Department of Literature."

"That in the judgment of your Committee, it is exceedingly desirable that every precaution be taken to prevent students incurring debts, and that in their opinion that object may be accomplished."

1. By suggesting to each parent or guardian, on placing a student at the College, to inform the authorities what sum it is contemplated by such parent or guardian to allow such student for expenses beyond the necessary and direct payments to the College.

2. By periodically cautioning tradesmen, by a public notice, in suitable terms, not to allow of the purchase of articles on credit, without the express sanction of parents or guardians, or of some officer of the College to whom that duty shall be specially delegated.

3. By desiring also, through the medium of the same notice, that all tradesmen's bills for articles supplied to students shall be regularly delivered to the same officer, and forwarded by him to the parents and guardians, at the end of every term.

4. By furnishing each student on entering the College with a list of such tradesmen as are sanctioned by the College authorities.

5. By providing in the bye-laws that all cases of extravagance which become known to the tutors, shall be immediately reported to the Council, and by the Council forwarded to the parents or guardians.

6. That every student three times proved to the Council to have incurred debts beyond his means, shall be dismissed.

James Thomas Law, Vice-Principal.
Charles Geach, Mayor.
John Birt Davies, M.D.
William Sands Cox, F.R.S.

General Retrospect.

PATHOLOGY.

INJURY OF THE SPINE: OBSTINATE CONSTIPATION.

While in Western New York, last summer, Mr. C. A. Green, of Milbury, Mass, U.S., saw a remarkable case, in the person of a young lady, who had had *but three fæcal discharges in nine years.*

The patient's name is Ellen R. Allis, daughter of Joel Allis. She lives about three miles from the centre of Batavia. When about twelve years of age, she attended a singing school, and being ensnared in a trap made of a rope by some boys, was thrown down, and her spine injured. She became quite sick, went to her bed, and there has remained up to the present time, perfectly bed-ridden. She is now aged 21. She lays in her bed, her body being at an angle of forty-five degrees with her extremities, nor can she be removed from that position without producing intense pain, and much dyspnœa. From her waist down, there has been no increase in size since her first injury, but above the umbilical region she has grown like other girls. She is wonderfully intellectual for one thus circumstanced, and has shown a remarkable skill in the formation of different curiosities. She has but little physical strength. Her heart beats like an infant's; her respiration is peculiar, and so slight is the effort, that it is hardly distinguished by a careful observer. Two days previous, and about three days after, the movements of her bowels referred to, she was perfectly insensible, and in a comatose state. About a teacupful of thin viscid discharge came from her at each time. There has been an attempt on the part of physicians in the region of Batavia to remove this difficulty, (whether it be a partial stricture of some portion of the intestines, or a want of action in them, is unknown,) but in vain. Her diet is very light, consisting mostly of white sugar and tea, and occasionally a thin broth. She has had but *three stools in nine years.* Oliver, in his physiology, makes mention of some persons having no discharge in one year; but no instance like the above has been recorded.—*Boston Medical and Surgical Journal.*

SURGERY.

REDUCTION OF DISLOCATED SHOULDER.

The patient being placed on a sofa or bed, or on the floor, the heel is to be placed in the axilla, (the same as for reduction by extension at the wrist,) and a long towel or narrow sheet is to be applied immediately above the elbow, embracing the condyles of the humerus, by means of the noose, and the two ends brought forward and tied firmly behind the back of the surgeon, he leaning forward a little while doing so. The towel

or sheet should be rendered damp at that portion which encircles the arm, and it should cross the back low down, over the lumbar region. The knee being kept straight, or nearly so, powerful extension can now be made, as the position of body is well adapted for the outlay of great physical strength, all the powerful muscles of the back being advantageously brought into play. At the same time the hand and arms are free, and the patient's forearm, being bent to a right angle with the upper arm, can be used as a lever in manipulating the reduction.—*Lancet*, June 3rd.

OBSTETRIC MEDICINE.

EXTRA-UTERINE FŒTATION.

The patient whose case is here narrated by Mr. Donald Dalrymple, was thirty-two years of age, in good health, and had borne five children. She said she became pregnant early in January, 1847, and quickened early in April. About the latter period she strained herself, and her subsequent feelings were different from what she had experienced on some former occasions. Shortly after this the uterus descended, and the author first saw her at the latter end of June, in consequence of this prolapse, the womb then protruding, of the size of a full-grown fœtal head, and presenting on its anterior surface a large ulcerated patch, of a purplish hue. The beat of the fœtal heart could be distinctly heard high up, but the placental murmur was not distinguishable. Rest and the recumbent posture were enjoined. At the end of September she had irregular labour-pains, which gradually subsided without the os uteri becoming dilated. From this time she ceased to feel the movements of the child, and soon diminished in size, and improved in health, until the middle of November, when her health became seriously affected. She suffered from increase in the size of the abdomen, great pain, shortness of breath, &c., and she died on December 23rd. On laying back the abdominal parietes, a thick layer of yellow lymph was found to line the internal surface of the peritoneum, within which was a large accumulation of thick sanious pus, not putrid. Immediately across the abdomen, above the umbilicus, lay a full-grown fœtus, which occupied a cavity, formed and bounded above by the intestines and omentum, and below by the pelvis: this space was covered by lymph, organized and highly vascular at parts. The head of the child was in the left hypochondrium, and the cord could be traced to a large, deep-coloured, spongy mass, apparently attached to the uterus, though that organ could not itself be made out, so irregular and confused was the mass. The child was well-formed, and weighed eleven pounds and a half. The author concluded by stating his belief, that the fœtus had escaped through an aperture in the uterus, which he conjectures was ruptured at the end of April, during the act of coitus, at which period, he was informed by the husband, a peculiar sensation was perceptible after a violent movement of his wife's body. He also remarked that the present is a case in which abdominal section would have completely failed, had a correct diagnosis been formed, and such an operation attempted.—*Lancet*.

REMARKS ON MR. NEWNHAM'S "PRESENT ASPECT OF MEDICINE."

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The concluding paragraphs in one of Mr. Newnham's communications to the Journal, on the "Present Aspect of Medicine," (p. 285,) have struck me rather forcibly, and have induced me to pen a few thoughts upon the subject to which those paragraphs refer. All who know Mr. Newnham, whether personally, or through the medium of his works, know well that he has typified his own character, when presenting us with the qualifications necessary to form a good practitioner. We know that he is conversant with those preliminary points which he regards as essential in the structure of a mind destined for the medical profession. To such a condition of mind who can raise an objection? Such vigour of intellectual capacity—who does not covet? Yet, Mr. Newaham knows that Nature has granted these privileges to very few, and that labour itself will not wholly overcome physical deficiency; for I do not think he belongs to that sect of philosophers who make the human mind a *tabula rasa*, upon which impressions may be made at will. Should such be his view, I am a dissentient. Nevertheless, to aim at perfection—to realize the utmost of which the mind is capable, is a privilege and a duty as imperative upon man in the advancement of his intellectual powers, as food is to the development and growth of his body,—nay, I will say more so, for the unerring standard of Divine truth tells us—

"Wisdom is the principle thing."

But Mr. Newnham has somewhat gratuitously assumed the possession of one article, at the command of practitioners, which I am disposed to believe is a commodity not so readily at their disposal. I allude to the article of "time;" and, moreover, he condemns those little meals of intellect which many of us are compelled to take, gathered from Retrospects and Journals. Now, I think Mr. Newnham must be sufficiently acquainted with the nature of general practice, to have learnt that the medical man's time is not his own,—that it is in the market, is offered for sale, is retailed at all hours;—that unlike the tradesman, he cannot close at nine o'clock, and refuse his customers because his shutters are up;—nay, that oftentimes the repose of nature is invaded, and his vigils are when others sleep.

I would not say that men in very extensive practice have not time for reading—I believe they have, and that many very precious moments are wasted; at the same time the difficulty is obvious for such men to digest voluminous tomes, either on medicine or any other subject, for in the midst of their reading and their ratiocination comes a voice at the study door—"Please Sir, you're wanted." The "tome" is left hastily on the study table, the intellectual feeder is galloping through storm and sleet, sunshine or shower, in light or darkness, and is perhaps compelled to sojourn for hours, listening to the garrulity of some antiquated nurse in a mob-cap, or half a dozen old

women, whose gabble is frightfully at variance both with his reading and his reasoning. I would remind Mr. Newnham of a very quaint but very ancient axiom—

"All work and no play, makes Jack a dull boy;"

And if he, in his extensive practice, has done what he advises others, let him thank God for a good constitution, as well as an active and vigilant mind.

After all, the man of true science—the really thinking man—wants no outward stimulant to urge him onwards; to cultivate his mind and to enlarge his capacity, is his enjoyment; and he does steal from the hours which nature has allotted for sleep, and the moments of respite from onerous and painful duties, to gratify his thirst for knowledge. If Mr. Newnham had the tongue of angels, he would never rouse the man to study who had not the inward impulse.

But the "Aspect of Medicine" exhibits a phase upon which your highly gifted and excellent correspondent would do well to enlarge. "The unspeakable luxury of ministering to the wants and weaknesses, and the infirmities of our fellow creatures," is a luxury, I admit, and under the operation of the New Poor-Law Bill, the only luxury the poor doctor is allowed to enjoy, the salary being a sort of legal fiction, as it is not only notoriously inadequate to pay him, but notoriously inadequate to furnish common appliances; while the fetters forged to bind him to his duties are so strong, that he requires the temerity, as well as unctuousness, of an eel, to slip them. Like the miserable horse harnessed to a thrashing machine, day by day his wonted circle must be fulfilled. But the phase to which I alluded, is the little estimate the public put upon his *science* and *attainments*. Men have no outward motives for labour and research, while they serve a community unable to appreciate either the ability or the service. Do the public employ practitioners according to their extent of reading? Do they judge of men wholly by their intellectual endowment, or by the force and energy of superior capacity? They may do so in localities where the petty influence of party or interest has no weight, but in the aggregate such valueless influence consigns a population to the tender mercies of consummate ignorance and impudence. And why is this? The public have no test for the talents and ability of professional men; and Mr. Newnham will not fail to answer—too true—when I assert, that the majority of gifted, reading, intelligent medical practitioners, will be found amongst the ranks of those who are least encouraged—have the least to do.

The "PRACTICAL MAN," so graphically described in the last "Journal," skims the cream of practice, and intrudes his ignorance, where intellect would do so much. The routine practitioner who has not a "tome," *who never reads*, who does not even dip into JOURNALS and RETROSPECTS, has no sympathy with science, except the science of gastronomy, no taste for improvement in his art, no desire to cultivate an acquaintance with progressive practice, who settles down upon the lees of an ancient *regime*, is full of nostrums for febrifuges and diaphoretics,—knows that blue pill acts *somehow* on the liver,—that sulphuric acid, water, and colouring matter, is an admirable remedy for paupers, let their ailments be as they may, because it looks nice, and is very *cheap*,—is heroic in his attacks on inflammation,—Quixotic in making mountains of mole-hills, and fighting windmills for giants. Now, these are the men, and numerous enough they are, Heaven knows, who, by *gossip*, by tact, by being "all things to all men," having a little of every thing, and much of nothing,—who are brass farthings burnished with little gold, looking like sovereigns, which pass current amongst the great and little vulgar, who hug them as though they were pure metal, and have not penetration enough to discover they are a base coinage. This is a phase in the "Aspect of Medicine" painful to every thinking and judicious mind, and marvellously galling to the *reader* and the man of science.

The man who follows his profession *con amore*, and really studies it because he loves it, requires no excitement but his own internal impulses to urge him in the pursuit, ardently, unweariedly; but, apart from this, what are the external inducements to make him wiser, and more truly practical, than the PRACTICAL or *routine practitioner?* Mr. Newnham has answered the query,—"The consciousness of his own deservings."—Very gratifying to his own feelings, but singularly inadequate in meeting the claims of the butcher, the baker, the tailor, and other necessary adjuvants to every establishment.

The "Aspect of Medicine"—the *countenance* of *our* Goddess has, through all ages of her sojurn amongst us, been so completely veiled, that the uninitiated are ignorant of her simplest features,—the public have never yet beheld even the glance of her eye. No wonder the world has been open to imposition, and that meretricious pretenders have assumed the habit, and walked in the pathway of the legitimate divinity. Hence quackery, with her bold and daring front, obtrudes her Protean shape, and in the highways, and even in the city streets, proclaims aloud, "I am she," and Princes and Dukes, and Lords and Commons, believe and worship. Give to the public some test whereby they can distinguish the true from the false; fear not to enlarge the intellect of mankind, for where is the practitioner who would not prefer to administer to a patient capable of understanding the principles of his practice, rather than to one who swallows compounds as a mystical means of cure, analogous to the obsolete system of philtres and incantations.

The elegant mind of Mr. Newnham,—the ease and freedom with which he can commit the workings of that mind to paper,—his extensive reading and acknowledged erudition, admirably fit him for the task of developing general principles,—not to the *elite* of the profession, for they are free, and need no spur,—not to the stupid and besotted, for the voice of the "charmer" will never rouse them, "charm he ever so wisely;" but to a sensible and thinking community, before whom the true "Aspect of Medicine" has never been properly exhibited, and consequently its real claims neither appreciated or nor understood. Why are the sons of the church and of the bar valued in proportion to their talent? The public itself possesses the touchstone

in these cases, and can separate the worthy from the unworthy. The genuine "Aspect of Medicine" would be beautiful, could they do so in our case.

I am, Sir,

Your obedient servant,

EDWARD DANIELL.

Newport Pagnell, June 5, 1848.

TESTIMONIAL TO JOSEPH HODGSON, ESQ., F.R.S., OF BIRMINGHAM.

A meeting (convened by Mr. Russell, Mr. Wickenden, and Mr. Thos. Chavasse,) of the professional and other friends of Mr. Hodgson, to consider the propriety of presenting him with some testimonial of respect and esteem, was held on Tuesday afternoon in the Concert Room of Dee's Hotel, and was attended by a highly respectable and most numerous audience, the room being completely filled. Amongst the gentlemen present were Richard Spooner, Esq., M.P., W. S. Dugdale, Esq., Hon. and Rev. G. M. Yorke; Messrs. Fowke, Wolverhampton; John Prichard, Leamington; Soden, Sunbury; Dr. Russell, Messrs. Russell, W. H. Partridge, Wickenden, Chavasse, W. P. Hodgson; Professor Partridge, King's College, London; Messrs. G. Edwards, Wolverhampton; Frederick Ryland, Alfred Baker, George Elkington, Francis Elkington, Dr. Bell Fletcher, Messrs. Bindley, Pye Chavasse; Dr. Conolly, London; Dr. Mackay, Dr. Wright, Mr. Thos. Freer, &c., &c., including a large number of the clergy and leading inhabitants of the town and neighbourhood.

The chair was taken at three o'clock by the Right Hon. Sir Robert Peel, Bart., M.P.

In opening the proceedings, the Right Hon. Baronet said, Gentlemen, I am satisfied it is quite unnecessary that I should detain you from the proper object of this meeting by any lengthened observations. That object is to mark our respect for the professional and private character of one of the most distinguished members of the medical profession. (Applause.) You are aware, gentlemen, that Mr. Hodgson has very recently signified to the Governors of the General Hospital of Birmingham, his desire to retire from the situation which he has held in connection with that Hospital. You are aware, also, that the Governors of the Hospital, at a special meeting, have come to an unanimous resolution, marking their deep sense of the services which have been rendered by Mr. Hodgson to that institution, and to all connected with it, for the long period of a course of twenty-six years. Gentlemen, we are assembled here for a similar purpose. We are assembled here, men of different pursuits, entertaining, probably, very various opinions on matters of public concern, but united this day for one common object—the desire publicly to acknowledge our respect for the professional and private character of Mr. Hodgson. (Applause.) Gentlemen, it is not, perhaps, altogether unsuitable that the duty of presiding on this occasion should be devolved, not upon an inhabitant of this great and important town, but should be devolved on one who has no immediate connection with the town, but residing at a considerable distance from it, and therefore, by occupying the chair on this day, marking in a significant manner that the services of Mr. Hodgson have not been rendered merely to this town or its immediate precincts; that they embrace a much wider sphere, and that respect for his character, and gratitude for his services—(applause)—are diffused over a very wide area. Gentlemen, there are many here who probably desire to express their gratitude, as members of the same profession, for opportunities of improvement in that profession, through the example and instruction of Mr. Hodgson. There are many here also, who, like myself, are desirous of expressing our gratitude for proofs of his professional skill—(applause)—who are desirous of bearing testimony not only to that professional skill, but to the zeal and assiduity with which he performed all his professional duties—to the sacrifice which he readily made of ease and comfort when the indulgence of them would have interfered with his professional labours—(applause)—and especially to that kindness and benevolence which has borne with indulgence the querulous impatience which sometimes is inseparable from severe suffering. (Applause.) Gentlemen, we are desirous, also, on this day, to mark our respect, not only for the professional merits of Mr. Hodgson, but for those private virtues which adorn his character. We are desirous of marking our respect for his high integrity—for his scrupulous honour—for those qualities which adorn the character of the Christian and the gentleman. (Applause.) And, gentlemen, it is not unfitting that we should on this occasion mark our respect for those virtues, for it is their possession that strengthens the resources and adds to the efficacy of mere medical skill. (Applause) It is the possession of those virtues that inspires the confidence which in many cases is essential to the successful treatment of disease. The possession of those virtues does more. It enables the physician, in cases where even the hope of prolonging life is extinct, to speak to the patient with a tone of authority, and to administer consolation and inspire hope when the narrow prospects of this world are about to close. (Applause.) Gentlemen, I know not what may be the intentions of Mr. Hodgson with respect to his continuance in this town in the exercise of the active duties of his profession. I earnestly hope that although relieved from his connection with the General Hospital at Birmingham, yet the wide district which has derived benefit from his exertions is not about to suffer the great injury which would follow his retirement from general practice. (Applause.) I trust, therefore, gentlemen, that we are not about to lose the great benefit of his continued pursuit of the profession to which he is an ornament; but I am sure when the time shall arrive when it will be fully necessary for him to retire from active occupation, and to quit its service, that he will recognize the claim which the public still have upon him to make the knowledge and experience which he has acquired by his connection with an institution which, perhaps, above all others, enables a medical man to become familiar with some of those accidents and diseases to which the human frame is liable,—I say I am sure that if Mr. Hodgson should contemplate his retirement, still he would not permit those lights of knowledge which can only be supplied by the practice and experience of near thirty years to be entirely extinguished—(applause)—that still you would have the benefit of his knowledge; for if any members of the profession might desire to repair to him for the purpose

of profiting by his experience, we know so much of his kindness and benevolence as to suppose that he would devote even his retirement to the public, if they could derive any advantage from his knowledge and enlightened understanding. Gentlemen, I speak on this point with the more confidence from having been desired to read to this meeting a letter from a most warm and sincere friend of Mr. Hodgson—from one who has been one of the greatest ornaments to that profession from the active pursuits of which he has retired. The letter is from a friend and neighbour of mine, Sir Charles Mansfield Clarke. He says, addressing myself and the committee of gentlemen :—

"Gentlemen,—The illness of my eldest son called me hastily from home to London, where the same cause detains me. Nothing short of such a circumstance should have interfered with my attendance at Birmingham on Tuesday, to testify the respect which I entertain for the professional zeal and talents of Mr. Hodgson, and my regard for him as a friend. I need hardly say that it will afford me great pleasure to assist in promoting the object you have in view.

"I remain, gentlemen, yours very faithfully,

"Charles M. Clarke.

"London, June 10, 1848."

Gentlemen, this letter is from one who, having attained every object which he could desire in his profession—having satisfied every desire for pecuniary gain—having received the highest distinctions which it has been the habit of the crown to confer, has retired from the active pursuit of his profession, but has not retired from the benevolent exercise of it on every occasion on which an appeal can be made to him. He has come into the immediate neighbourhood in which I reside; and, gentlemen, I can say with truth, that no one medical man has resorted to him in vain for advice in any difficult case,—there is no one, rich or poor, who felt anxiety for any near relation, whose appeal for aid he would not attend to with as much of kindness, of devotion, and self-sacrifice, as would have marked his career at the most active period of his life. (Applause.) And it is gratifying to me to be enabled on the same occasion to pay a tribute of respect to Mr. Hodgson, and also to convey the thanks of the neighbourhood, who feel the residence of Sir Charles Mansfield Clarke to be a blessing, and to express their unanimous feeling of gratitude for his constant disposition to render his great knowledge and experience availing for the mitigation of human suffering. Whenever Mr. Hodgson shall follow his example as to retirement, I feel convinced that Mr. Hodgson will follow also his example, of making the knowledge and experience which he has acquired during a long course of professional practice equally conducive to the mitigation of human suffering. (Applause.) Gentlemen, I have peculiar pleasure in attending on this occasion, because having had many opportunities of intercourse with the medical profession, I am proud to acknowledge in as marked a manner as I can, my deep conviction, that in no profession can there be found more frequent instances of liberal and dignified sentiment, or more proofs of active and enlightened humanity. (Applause.) Gentlemen, it seems to me, that their familarity with pain and suffering tends largely to brace the nerves, and gives that presence of mind, the exercise of which is indispensable to the treatment of severe affliction; yet at the same time this familiarity with pain and suffering softens the mind, and disposes them to the exercise of benevolence to those who suffer. (Applause.) And, gentlemen, by expressing our gratitude for the services, and our respect for the character of one of the most distinguished ornaments of that profession, I consider we are not merely acting in accordance with private feeling. I consider we are performing a public duty, and promoting a public object—that we are supplying to other members of that profession a stimulus to continued exertion—that we are proving to them that we generally believe they are influenced by other motives than the mere desire of pecuniary gain—that we believe they are influenced by the honourable ambition of doing good, and of acquiring an honourable fame. I say we are promoting a public object, and supplying them with a powerful stimulus to exertion, when we prove (as we shall prove by the result of this meeting,) that years of severe and successful labour will not pass unnoticed in this immense district, including this great town—including all the precincts which border upon it—including that great area within which the name of Mr. Hodgson is known and respected;—when we shall prove that after years of public service there is a disposition on the part of those who respect talent, combined with virtue, to leave some permanent record of their respect, their admiration, and their gratitude. (Applause.) Gentlemen, with these observations, I propose that we now proceed to the immediate business of the day.

Mr. Russell offered some remarks in explanation of the motives which had influenced himself, and the two friends who were associated with him in the business, to take upon themselves the responsibility of convening the present meeting. It was the anxious wish of Mr. Hodgson's friends that some testimonial should be offered to him, and they were of opinion that the occasion of his retiring from his public duties at the General Hospital was a fit opportunity for the presentation of such testimonial. They had endeavoured to carry out their views in such manner as they believed would be most in accordance with the wishes of their medical brethren and of the public at large, and he did not think they would be charged with having presumed to undertake an office to which they were not entitled. He had been the attached friend of Mr. Hodgson for near half a century, and he and the two friends in question were now getting into the rank of senior members of the profession. They were all three, moreover, dissociated from the various medical charitable institutions in the town. It was a source of deep gratification to them that their humble efforts were so warmly responded to. The first office was to select a chairman for that occasion, and he felt assured all present would agree that they had not shown themselves altogether incompetent to the task. There were various circumstances to direct their attention to Sir Robert Peel, the principal being the deep debt of gratitude under which the medical profession, as well as mankind at large, lay to the Right Hon. Baronet for having introduced the Anatomy Bill into Parliament; upon which occasion Sir Robert Peel passed a high eulogium upon Mr. Hodgson. They also knew that Sir Robert Peel had reposed great confidence in the professional skill of Mr. Hodgson. For these various

reasons, they had no hesitation in believing that if a respectful request that he would preside was conveyed to him, the Right Hon. Baronet would have the kindness to comply with their wishes. They had, accordingly, put themselves in communication with him, through the medium of their friends Professor Partridge and Mr. Parkes. Their application was successful, and he begged to tender their cordial thanks to Sir Robert Peel for having so kindly consented to take the chair.

It was then resolved that a subscription should be entered into for the presentation of a portrait of Mr. Hodgson, to be painted by some artist of eminence, to the General Hospital, Birmingham, the subscribers to be severally entitled to engravings of the portrait on India paper, to proofs with the autograph, or to copies with the name printed according to the sum subscribed.

Medical Intelligence.

THE EPIDEMIC CHOLERA.

Accounts from St. Petersburgh state that the cholera is making alarming progress at Moscow; 464 fresh cases, and 205 deaths, occurred in the last week of May. The cholera has also broken out with severity at Jaroslaw, Robinsk, and Kalouga.

PUBLIC HEALTH BILL.

The Public Health Bill was read a third time, and passed the House of Commons on Monday, June 19th.

TESTIMONIAL TO DR. RANSFORD.

The Royal College of Physicians of Edinburgh have voted a piece of plate of the value of fifty guineas, to Dr. Charles Ransford, late Treasurer to the College, who has left Edinburgh.

RETIREMENT OF DR. CHAMBERS.

We regret to learn that this distinguished physician is compelled by ill-health to retire from the metropolis into the country, with little probability, it is said, of being able again to take an active part in the arduous duties of his profession.

APPOINTMENT.

Alfred Baker, Esq., has been elected one of the Surgeons to the General Hospital, Birmingham, in the room of Mr. Hodgson, resigned.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members Friday, June 16th:—C. W. M. Bloxham; S. Ffolliott; R. E. Price; W. B. Norcott; E. W. Sullivan; J. Morris; J. Sinclair; J. E. Elam; C. S. Smith.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, June 8th:—William Costall May, London; Thos. Limbury, Appledore, Devon; Charles Crighton Bramwell, North Shields; Robert Thomas Deakins, Bicester; James Eyres Coward, Tiverton; John Sinclair, Liverpool.

Thursday, June 15th:—Edward Marshall; Henry Wright Slack, Liverpool.

OBITUARY.

Died, May 29th, at Malta, Arnold John Burmeister, M.D., from the accidental discharge of a pistol in his own hand.

June 8th, at Leamington, aged 63, Thomas Hiron, Esq., Surgeon for nearly forty years, an eminent practitioner at Warwick.

June 15th, at Cambridge, aged 35, John Linley Sudbury, Esq., Surgeon.

June 17th, at Mile-end, aged 65, George Edwardes Carruthers, Esq., Surgeon to the Queen's Own Light Infantry Militia.

At his residence, Mary Street House, Taunton, aged 71, Stephen Henry Macmullen, M.D., F.R.C.P., Edin., H. P. Army Medical Staff. Dr. Macmullen entered the Army at an early age, and served with the 59th Regiment in the East and West Indies, and in the Peninsula. He was appointed President Elect of the Provincial Medical and Surgical Association, at the last Anniversary Meeting of the Association, at Derby.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNIVERSARY MEETING.

In consequence of the Annual Meeting of the British Association having being fixed to be held at Swansea on the 9th and 10th of August, it has been found necessary to postpone the Meeting of the Provincial Medical and Surgical Association to the following week. The Anniversary will therefore now be held at Bath, on Wednesday, the 16th, and Thursday, the 17th of August.

R. J. N. STREETEN, Secretary.

NEWTON BRANCH.

ANNUAL MEETING.

The Annual Meeting of the Newton Branch of the Provincial Medical and Surgical Association, will be held at the Leigh Arms Hotel, Newton, on Thursday, June 29th, Sir Arnold Knight, M.D., President, in the chair.

JOHN HATTON, Manchester,
G. C. WATSON, M.D., Liverpool, } Secs.

ERRATUM.

At page 325, in the heading of the seventh column of the table, for "*death*," read "*cure*."

TO CORRESPONDENTS.

Communications have been received from Mr. Nunneley; Mr. H. Hanks; Dr. Blackmore; the Birmingham Pathological Society; Mr. Crompton; Mr. W. S. Cox; Mr. Husband; Mr. Bree; Dr. Forbes.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

LOCAL ANÆSTHESIA:

NOTES ON ITS ARTIFICIAL PRODUCTION BY CHLOROFORM, &c., IN THE LOWER ANIMALS, AND IN MAN.

By J. Y. Simpson, M.D., F.R.S.E.
Professor of Midwifery in the University of Edinburgh.

A few months ago I published some remarks with the object of shewing that the artificial production of a state of general anæsthesia before the performance of surgical operations was not, altogether, an idea of modern times.* Several ancient writers aver that such a state of general anæsthesia can be produced by using mandragore,—as Dioscorides'† Pliny,‡ Apuleius,§ &c.‖ In the thirteenth century, Theodoric,¶ published a receipt for producing it by the *inhalation* of vapours arising from the watery extracts of various narcotic herbs, and in our own days, (1832,) this receipt of Theodoric's has been, apparently, found quite sufficient for the purpose by Dauriol.**

The ancients also seem to have entertained the idea of the possibility of producing a state of *local* and limited anæsthesia in any part to be operated upon. Dioscorides, who, as we have seen repeatedly, mentions the production of general anæsthesia by mandragore states it as a matter of report that local anæsthesia in a part was capable of being produced by the Memphian stone. "The Memphian stone (says he,) is found in Egypt near Memphis, of the size of a calculus, fatty and of different colours. They say that this, when bruised, and spread over parts that are to be cut or cauterized, so anæsthetizes these parts that they do not feel pain."††

Whilst we may entirely doubt whether local anæsthesia was capable of being produced by such an apocryphal application as the above, the passage is curious, as evidence that the idea of obtunding a single part of the body against the pain of an operation was not unknown nor unthought of in former times. Nay, many old authorities believed that against the fire-ordeal any part of the body could be so protected and

† Dioscoridis Opera. Liber iv. Cap. 76. In this chapter on the mandragore, Dioscorides mentions its anæsthetic virtues repeatedly. 1. "Some (says he,) boil down the roots in wine to a third part, and preserve the juice thus procured, and give one cyathus of it in sleeplessness and severe pains of whatever part; also (it is given) *to cause the insensibility* (ποιειν ανεσθησιαν) *of those who are to be cut or cauterized.*"

2. "There is prepared also, besides the decoction, a wine from the bark of the root, three *minæ* being thrown into a cask of sweet wine; and of this three cyathi are *to be given to those who are to be cut or cauterized, as aforesaid; for, being thrown into a deep sleep, they do not perceive pain.*"

3. Again, of another mandragore, called "morion," Dioscorides observes, "Medical men use it also for those who are to be cut or cauterized."

‡ C. Plinii Secundi Natur. Hist. Lib. xx. Cap. 13. Speaking of the circeius or mandragora, he says, "It is drunk against serpents and *before* cuttings and puncturings, *lest they be felt.* (*Bibitur et contra serpentes et ante sectiones punctionesque, ne sentiantur.*)

§ *L. Apuleii de medicam. herbarum Liber*, published in a collection of works, entitled, "*Parabilium medicamentorum scriptores antiqui.*" p. 294. Apuleius remarks, "If any one is to have a member mutilated, burned or sawed, *(mutilandum, comburendum, vel serrandum,)* let him drink half an ounce with wine, and let him sleep till the member be cut away without any pain or sensation, *(et tantum dormiat, quousque abscindatur membrum aliqno sine dolore et sensu.*"

‖ Ambrose Paré's Works. Liber xxi. Cap. 35. When "Mandrage is taken in great quantity, (says Paré,) the patient falls asleep in the same posture as he was in, just as if he were in a lethargy. Wherefore, in times past they gave mandrage to such as were to be dismembered."

¶ See page 146 of a collection of Surgical Treatises in blackletter, printed at Venice, in the year 1519, and entitled, "Cyrurgia Gurdonis de Canbaco, et Cyrurgia Bruni, Theodorici, Rolandi, &c. In the rubric of the work the receipt is described as "Spongia somnifera," and is described thus:—"The preparation of a scent for performing surgical operations, according to Master Hugo; it is made thus:—Take, of opium, and of the juice of the unripe mulberry, of hyoscyamus, of the juice of the hemlock, of the juice of the leaves of mandragore, of the juice of the woody ivy, of the juice of the forest mulberry, of the seeds of lettuce, of the seeds of the burdock which has large and round apples, and of the water hemlock, each oz. j.; mix the whole of these together in a brazen vessel, and then in it place a new sponge, and let the whole boil; and as long as the sun on the dog days, till it (the sponge) consumes it all, and let it be boiled away in it, [or, in other words, let a watery extract be so formed.] As often as there is need of it, place this same sponge into warm water for an hour, and let it be applied to the nostrils till he who is to be operated upon *(qui incidendus est,)* has fallen asleep, and in this state let the operation be performed, *(et sic fiat chirurgia.)* When this is finished, in order to rouse him, place another sponge dipped in vinegar frequently to his nose; or let the juice of the roots of fenugreek be squirted into his nostrils. Presently he awakens."

†† Dioscoridis Opera. Liber v. Cap. 158. "Hoc tradunt trito et illito partes quæ urendæ secandæve sunt, citra periculum, ita obstupescere ut non sentiant cruciatum, (ανεσθησιαν ακινδυνον επιφερειν.)

defended by previous applications; that the human hand, for instance, should not feel the contact of the red-hot iron. The writings of Eusebe, Salverte, and of Beckmann, contain ample notices on this disputed question. Upwards of half a century ago, our countryman, Dr. Moore, ingeniously proposed to effect a local anæsthesia of any limb that was to be operated upon, by previously compressing with tourniquets and pads the nervous trunks going to that limb; and he has left us one interesting account* of a case of amputation at St. George's Hospital, in which this plan was tried, with partial success, by John Hunter.

The possible production of local anæsthesia by this or other means is certainly an object well worthy of study and attainment. Surgeons everywhere seem to be more and more acknowledging the facility, certainty, and safety, with which the state of general anæsthesia can be produced at will before operating, and the moral and professional necessity of saving their patients from all unrequisite pain. But if we could by any means induce a local anæsthesia without that temporary absence of consciousness which is found in the state of general anæsthesia, many would regard it as a still greater improvement in this branch of practice. If a man, for instance, could have his hand so obtunded that he could *see* and yet not *feel* the performance of amputation upon his own fingers, the practice of anæsthesia in surgery would, in all likelihood, advance and progress still more rapidly than ever it has done.

In the following remarks it is my object to state the results of a number of experiments which I have performed upon the lower animals, and two upon man, with a view to the possibility of the production of such a state of local anæsthesia, by the local application of chloroform or other anæsthetic agents, to individual parts of the body.

I. The Production of Local Anæsthesia in the Lower Animals.

At a meeting of the Medico-Chirurgical Society of Edinburgh, held on the 17th March, I took occasion to state that I had successfully chloroformed several of the lower animals,—annelida, crustacea, fishes, &c.; that in some, especially in the common earthworm, (*Lumbricus terrestris*,) I had been able to produce local anæsthesia by applying the chloroform vapour locally, and had thus, at will, rendered anæsthetic, individual parts and portions of the worm, as the head merely, or the tail merely, or the middle part of the worm merely, the head and tail remaining unaffected. At the same time I recapitulated what I had stated at one of the February meetings,—that, in the human subject, local anæsthesia of a portion of the gums could be produced by rubbing the part with hydrocyanic acid. After the date of the above meeting, I was led to make some additional experiments upon the possible production of local anæsthesia in man; and in reporting the proceedings of the preceding sederunt of the Society, in the last number of the "Monthly Journal of Medical Science," the Editor has stated, in a short foot note, some of the results of those experiments upon the human subject, which I here intend to detail at greater length.—See "Monthly Journal," No. xci., p. 48.

Nothing could be more curious or satisfactory than the experiments alluded to on the production of local anæsthesia by the local application of chloroform vapour to different parts of the body of the earth-worm. The resulting degree of local anæsthesia in the part exposed is generally, in the course of two or three minutes, most complete, as regards both sensation and motion; in fact, after being sufficiently exposed, the chloroformed portion of the animal is quite flat and flaccid, does not move under any irritation, and can be doubled and twisted up upon itself like a piece of loose wetted cord. If the part paralysed by the chloroform is small, it will be dragged along by the movements of the other unaffected portions of the worm. Generally, in the course of a few minutes,

* *A Method of Preventing or Diminishing Pain in several Operations of Surgery. By James Moore, Member of the Surgeons' Company London.*—"I communicated (says Mr. Moore, p. 30.) the experiments I had made, and all my ideas on the subject, to Mr. Hunter, who was so obliging as immediately to offer me an opportunity of trying the effect of my compressor, at St. George's Hospital, on a man whose leg he was to take off below the knee within a few days. I went to the Hospital the day before the operation to try the instrument. The patient had lost all his toes, and had a large ulcer on his foot. This was so much inflamed and so irritable that dressing it in the gentlest manner gave him acute pain. I applied the instrument; after the compression had been continued for about half an hour, his limb became so insensible that rubbing pretty smartly with the finger upon the ulcer gave no pain. Next morning, the patient being carried into the operation room, I began the compression of the nerves at a quarter before eleven o'clock. The numbness of the limb followed at the usual time. At a quarter before twelve I gave him one grain of opium to diminish the smarting of the wound after the operation, when the compression should be taken off. A few minutes after twelve the tourniquet was applied, and the amputation performed by Mr. Hunter, at the usual place below the knee.

"At the circular incision through the skin, the patient did not cry out, change a muscle of his face, or shew any symptoms of pain. At the subsequent parts of the operation, particularly during the sawing of the bones, he shewed marks of uneasiness in his countenance, but did not cry out. As it was thought necessary to take up no less than five arteries, the operation lasted a longer time than is usual, and towards the end he grew faintish, and desired to have some water, and afterwards asked if they were nearly done. When the operation seemed to be over, and the bleeding stopt, the tourniquet was relaxed, and I also removed the compressor; but a small vessel bleeding unexpectedly, it was thought necessary to tie it also. Here the patient shewed very strong marks of pain, and afterwards declared that tying this last vessel gave him much more pain than all the others, although the great nerves had been included in the ligatures. When he was put to bed the wound smarted, as is usual after amputations. The compressor being now entirely removed, this was to be expected. But some time after, being questioned concerning the pain he had suffered during the operation, he declared that he had felt hardly any, except (as he himself expressed it,) at the rasping of the bones, which, he added, had shaken his whole limb. This seems a little extraordinary, as sawing the bones is usually the least painful part of amputations." * * * "This trial had all the success I expected; there was evidently a most remarkable diminution of pain, particularly during the first incisions through the skin and muscles, which are generally by far the most severe parts of the operation, and I am convinced that what pain the patient felt was chiefly owing to some small branches of the lumbar nerves which extend below the knee, and were not compressed."

it gradually regains its powers of motion, and its irritability and contraction under stimuli.*

The easiest method of performing this experiment, is to place a small quantity of chloroform in the bottom of a tumbler, paste over the mouth of it a covering of paper, and making an aperture in this covering sufficient only to admit the portion of the animal that is to be chloroformed. When held in this position, the part of the animal below the paper and exposed to the vapour of chloroform, is generally thrown into violent movements, for a minute or two before the state of anæsthesia supervenes. I have repeated the same experiments with the vapours of sulphuric æther and of bisulphuret of carbon.

I have tried the same experiment with the same results upon the medicinal leech.

The results were, if possible, still more marked in another of the articulata that was submitted to experiment. A small myriapede or centipede, *(Iulus sabulosus?)* was rendered completely anæsthetic and motionless in the posterior segments of its body, by exposing that part alone for a few minutes to the vapour of chloroform. The five or six last rings of the centipede, with the suspended and motionless feet attached to them, were, for a short time afterwards, dragged about in a kind of paraplegic state, by the brisk and lively movements of the anterior and unaffected portion of the animal. The animal soon and completely recovered, each segment with its corresponding feet regaining its power of motion, and this in regular order from before backwards.

In other centipedes experimented upon, a small quantity of fluid chloroform was applied by a slight brush to the head, or to two or three of the middle rings of the animal, or to the tail, and always with the effect of anæsthetizing and paralysing the part or parts only with which the chloroform came in contact. Sometimes when the head and anterior rings were alone touched, the animal after vainly trying to push its motionless head forwards, reversed the movements of all its limbs for a time, and dragged the paralysed head behind it. All of the centipedes experimented on recovered in a few minutes from the effects of the chloroform.

By immersing the tail of the water-newt in chloroform vapour, the insensibility and motions of that part were rapidly destroyed, and returned in a few minutes afterwards. By a longer degree of immersion of the tail alone, the whole animal became anæsthetic; and in several experiments it was found possible, but difficult, to give the animal in this way a fatal dose of the vapour.

The hind-leg of the frog becomes anæsthetic when exposed for four or five minutes to the vapour of chloroform. Immediately after, it drags the limb in progressing, and bears, apparently without feeling, pricking and irritation of it; but a galvanic current passed through it excites both sensation and motion. In one case, the motory power of the limb was not restored at the end of the third day. No effect appeared to result from keeping the hind-leg of this animal immersed in strong tincture of Indian hemp.

One hind-leg of a healthy, active rabbit, was confined in a large bladder containing the vapour of chloroform. At the end of an hour the common sensibility of the limb to pinching and squeezing was much impaired; but a current of galvanism passed through it produced crying and signs of pain. The power of moving the limb seemed unimpaired.

The hind-leg of a guinea-pig, similarly treated, exhibited the same phenomena at the end of an hour; but the anæsthesia was more complete. The skin of the leg was red and congested.

The posterior extremities and pelvis of a strong guinea-pig were enclosed in a bag containing the vapour of chloroform. At the end of an hour, no signs of pain could be extracted by pinching and squeezing either limb; and a current of electricity passed through a hind-leg evidently caused much less pain than when the same current was passed through a fore-leg. The whole hinder parts were very red and congested. The animal was also, in some degree, paraplegic, and dragged itself along by strong efforts with its anterior limbs.

In an interesting communication addressed on the 7th of June to the Yorkshire Branch of the Provincial Association, and published in the last number of the *Provincial Journal*, Mr. Nunneley, of Leeds, has stated that he has produced complete paralysis of the individual limbs of frogs and toads, by immersion or exposure of them for a few minutes, to the vapour of chloroform; that by a similar but longer immersion, he had rendered the leg of the rabbit sufficiently anæsthetic to bear mutilation without pain; that he had immersed his own finger in anæsthetic fluids for about half an hour or an hour, and at the end of that time it was nearly powerless and insensible, nor was entirely recovered for forty-eight hours; that in operating on the human eye he had rendered the organ anæsthetic by previously exposing it for about twenty minutes to the vapour of chloroform; and that, in his opinion, the action of all, or of most anæsthetic agents might be produced locally by their local application, the sensorium being unaffected, consciousness retained, and the limbs not subjected to their influence being unaffected. This naturally leads us to the consideration of—

II. The Production of Local Anæsthesia in the Human Subject.

Early in February last I was led to make the experiments to which I have previously alluded, relative to the artificial production of *local anæsthesia* in a portion of the human gums by friction with hydrocyanic acid, in consequence of being assured, on what I believe to be satisfactory evidence, that a dentist at Limoges, in France, M. Pernot, had the secret of extracting teeth with little or no pain, in consequence of previously applying some obtunding agent to the gums. I tried at the time a great variety of substances, in order to obtain this local anæsthesia, such as various æthers, bisulphuret

* These experiments become the more interesting in a physiological and toxicological point of view, when we recollect, that in the articulata the vascular system is general and distributed longitudinally, while both the nervous and respiratory system of this class of animals is, in a great measure, segmentary and isolated, like the action of the anæsthetic.

of carbon, benzin, aconite, &c. Among all the agents employed, the effect of prussic acid was by far the most decided and complete; any part of the gum strongly rubbed by it, speedily became benumbed and insensible; but the resulting degree of anæsthesia was by no means sufficient for the purpose required. The results of these experiments were stated orally to the Edinburgh Medico-Chirurgical Society, at their meeting on the 16th February.

Before that date I had met with one instance in which local anæsthesia of the human hand had been produced in a young lady, in consequence of her accidentally holding in it for a considerable time a scent-bottle containing some chloroform. I tried at various times to reproduce a similar result in myself and in others, by keeping my hand wrapped in a napkin soaked in chloroform and other anæsthetic agents, but with little or, indeed, no decided success, till I used the vapour of chloroform raised by heat, the hand for the purpose having been immersed in a deep jar, into which a small quantity of chloroform was poured—the jar temporarily placed in a basin of water of the temperature of 130° or upwards, and the wrist or fore-arm being surrounded by handkerchiefs, so as to prevent the escape of the vapour.

A number of circumstances influence, however, the effect and the degree of it; and as I have made a considerable variety of experiments, both upon myself and upon others, in order to ascertain these points, I will shortly state the results. Let me premise, that in the experiments upon which the following results are founded, the hands of the same individual were generally held simultaneously in two different jars, differently arranged in regard to material or otherwise, in order to make two different and comparative experiments at the same time; and the relative degree of anæsthesia in each hand was ascertained during the experiment by pincing the fingers with the thumb nail, without removing the hand from the jar. After they were removed, these and other more severe measures were used with the same view, as tests of the degree of anæsthesia. Most of the experiments referred to were repeated and tried upon several different individuals. The general results were the following:—

1. When the hand is exposed to an anæsthetic vapour, it betimes presents the sensations of a limb benumbed, by compression of its larger nervous trunks,—the sensations, in fact, of partial or commencing paralysis. Usually after a short time, a glowing or burning feeling is perceived in the parts most exposed, and gradually there supervenes a sensation of thrilling and prickling (like a limb asleep,) which deepens more and more. The skin turns red, and the hand at last becomes stiff and clumsy, and feels as if enlarged, and painful impressions, as pricking, pinching, &c., are felt less and less than in the other unexposed hand. After the hand experimented upon is removed from the vapour, it is generally half an hour or more before its usual normal feelings are quite restored: The nerves of motion are usually apparently as much affected as the nerves of sensation.

2. When the jar containing the chloroform or other anæsthetic fluid experimented upon, was immersed in warm water, so as to raise the vapour of the fluid more fully and quickly, the resulting anæsthetic effect was always greatly increased, both in rapidity and intensity.

3. The vapour of chloroform proved stronger than any other that was tried. When one hand, for instance, was immersed in a jar containing the vapour of sulphuric æther, and the other in a jar containing the vapour of chloroform, (both jars containing similar quantities, and being subjected to the same degree of heat,) the hand in the chloroform jar was both more speedily and more deeply affected than the other. In addition to the vapour of chloroform and æther, I have tried comparative experiments with the vapours of aldehyde, bisulphuret of carbon, iodide of methyle,* &c. The aldehyde had little or no effect of any kind. The iodide of methyle produced a very severe burning sensation, and left the hand intensely red and erythematous for a day or two afterwards, but with no marked anæsthetic influence. Among several of us that tried the vapour of bisulphuret of carbon, only one bore it for any length of time, (about an hour,) and in him it did not render the hand anæsthetic in any very appreciable degree; in myself and others the sensation of heat and burning became so utterly intolerable, as to force us to withdraw the hand in two or three minutes. Immersion of the hand for half an hour in Dr. Fleming's very powerful tincture of aconite,† or in a strong tincture of opium and of Indian hemp, and in a strong solution of belladonna, produced no appreciable anæsthetic effect.

4. The hand, when plunged in liquid chloroform, is usually somewhat more deeply apathized than the other hand simultaneously held in the vapour of chloroform. This was the more general result with those who tried the experiment; but in some the chloroform vapour was as anæsthetic, or more so, than the liquid. Few persons can keep the hand for any adequate length of time in liquid chloroform; the sensation of burning becomes so intense and insufferable, as to force them to withdraw it in a very few minutes. On one occasion I held my hand for upwards of an hour in liquid chloroform without the part being more deeply apathized than it would have been by exposure to the vapour. One of my pupils, Mr. Adams, perseveringly retained his hand in the liquid chloroform for upwards of two hours: no great or very marked degree of local anæsthesia resulted. In these cases, in which the hand was long steeped in liquid

* Two or three months ago I began a series of experiments with the intention of testing the anæsthetic effects (if any) of the various respirable compounds of methyle, acetyle, &c. I was proceeding far in the inquiry, in consequence of the effects following the inhalation of the compound mentioned in the text,—viz., iodide of methyle. I found it very powerfully anæsthetic, but dangerously so. After inhaling a small quantity of it for two or three minutes, I remained for some seconds without feeling much effect; but objects immediately began to multiply before my eyes, and I fell down in a state of insensibility, which continued for upwards of an hour. I did not recover from the effects of it for some days.

† Some other forms of preparations of this and the other substances may possibly produce different results, as we know that aconite, when chewed, causes a numbness and tingling in the lips and tongue, lasting for some hours,—See "Christison on Poisons," p. 2.

chloroform, the sensations of burning returned severely, from time to time, as if in waves, during the experiment; and on removing it from the jar, the feelings of heat were temporarily aggravated; the normal sensibility of the parts speedily returned, and was completely restored within an hour or two in all, but the skin sometimes remained red and injected for a longer period, occasionally for several hours.

5. The anæsthetic effect of chloroform, &c., is increased, both in rapidity and in degree, by immersing the hand, with the cuticle softened and moist. When one hand, for instance, is immersed without any preparation, and the other is prepared by being bathed and fomented for ten or twenty minutes previously, the latter almost immediately begins to tingle under exposure to the vapour, the dry hand not for some minutes; the degree of anæsthesia is also ultimately deeper in the moistened hand.

6. The degree of delicacy of skin in the person or part exposed to the anæsthetic vapour influences the result. In females I have seen the degree of the local anæsthesia of the hand that was produced, much greater and deeper than I could ever render it in the male subject. In applying the vapour of chloroform in small cupping glasses, &c., to different parts of the body, as the insides of the arms, &c., the resulting degree of local anæsthesia seemed, in a great measure, regulated by the tenuity of the skin of the part experimented upon. The skin of the axilla seems two tender to allow of the vapour being applied for a length of time sufficient to produce anæsthesia. One of my students, who kept both his lower extremities enveloped in strong chloroform vapour for three continuous hours, felt no appreciable local anæsthetic effect from it.

When strong chloroform vapour is locally applied to mucous surfaces, the attendant sensations of heat and smarting are too severe to allow of its sufficient continuance; at least, this is the result that I have obtained in applying it with small glasses to the inside of the lips, the tongue, and eye. Mr. Nunneley states, as we have already mentioned, that before operating on a difficult case of artificial pupil, he had applied for twenty minutes, a small quantity of the vapour of chloroform to the eye, by means of a small jar which accurately filled the orbit, with the effect of rendering the parts nearly insensible. Dr. Duncan and myself have repeatedly tried this experiment upon ourselves; but in none of the trials which we made, with the eye either shut or open, could we endure the burning action of the vapour upon the part above two or three minutes, and with no other result except always rendering the eye experimented upon red and injected, and suffused with tears.*

The degree of anæsthesia produced in the hand by exposure of it to the strong vapour of chloroform, does not, in general, perceptibly increase after fifteen or twenty minutes. The same sensations continue if the hand is still retained in the jar; but an increased length of exposure does not, after a time, produce a corresponding increased degree of local insensibility.

But, finally and specially, I would observe that the degree of local anæsthesia produced in the human hand or skin, by exposing it to the local action of the vapour of chloroform, has never, in my experiments, been by any means so deep and complete in its character as to give the chance of annulling the pain of any severe operation, such as the deep incision, or amputation of a finger. As compared with the other non-exposed hand, the chloroformed hand is generally rendered, to a marked amount, *less* sensitive; but the insensibility is never, I fear, so entire and perfect as will save the patient from the pain of the surgeon's knife. In short, I entirely doubt, whether, in the human subject, we shall ever be able to reduce the knowledge of this possible production of partial local anæsthesia to any practical purpose. It is principally interesting in a toxicological and physiological point of view, and in relation to the doctrine of the mode of action of anæsthetic agents.† Its bearings are more upon the theory than upon the practice of anæsthesia.

These remarks relate to local anæsthesia as capable of being produced by the anæsthetic agents with which we are at present acquainted. Others may no doubt yet be detected, much more powerful than any we at present know,‡ and their local application may enable us to

* I have tried the application of various anæsthetic gases and vapours to the vagina, in cases of vaginal irritation and neuralgia, but hitherto without much success. The stronger forms cannot be borne. I was induced to try them in consequence of the following curious statement regarding carbonic acid, published by Dr. Pereira, ("Materia Medica," Vol. I., p. 155,)—"A lady who had suffered a considerable time from some uterine affection, and had derived no relief from the treatment adopted, was advised to consult a physician in Italy. (Dr. Rossi.) After he had examined the condition of the uterus, he assured her there was no organic disease, but merely a considerable degree of irritation, for which he proposed to apply carbonic acid as a sedative. This was done by means of a pipe and tube, communicating with a gasometer situated in another room. The patient obtained immediate relief, and although she had been obliged to be carried to the doctor's house on account of the pain experienced in walking, she left it in perfect ease. On her return to England, she had a relapse of the complaint, and applied to Dr. Clutterbuck to know whether she could have the same remedy applied in London, in order to save her the necessity of returning to Italy."

† The distinction which exists between the structure and functions even of the skin in the lower animals, as compared with the skin of the human subject perhaps sufficiently explains the differences in the degree of local anæsthesia, capable of being produced by the local application of anæsthetic vapours and fluids in the one and in the other. "In animals, (says Mr. Jackson, see American Cyclopædia of Pract. Med. and Surgery, &c., vol. i. p. 115,) whose skin is moist, and which possesses a very delicate cuticle, cutaneous absorption is a constant and important function. Such are frogs, salamanders and similar animals. The experiments of Edwards have established the skin in them to be entirely absorbing, and instrumental in their support. It is the opinion of Fohmann, that while the fœtus is in utero, cutaneous absorption from the liquor amnios by which it is surrounded, is one of the means of its nutrition."

‡ Perhaps some special modification in the application of galvanism or magnetism to the part to be locally anæsthetized, may yet be found capable of effecting this object. I have tried several experiments, but hitherto without much success. The possibility of deep *local* anæsthesia existing in diseased states, (as in colica pictonum, hysteria, hypochondriasis, &c.,) without the general sensibility or consciousness being affected, is well shewn in a late interesting essay of M. Beau, in the "Archives Générales de Médecine" for January, 1848. He relates one case of an

effect the local anæsthesia desired. At the same time, this consummation, even, seems doubtful; for, perhaps, any agent possessing a deeper and more rapid anæsthetic local power, would, by absorption, affect the system generally, and it may be, dangerously, before complete local insensibility of a part could be effected. Some time ago, in attempting to produce local anæsthesia in my hand, by exposing it to the vapour of hydrocyanic acid, ere the hand was much, or very perceptibly benumbed, I began to feel the constitutional effects of the poison; my respiration became irregular, and I felt giddy and faint, when my assistant removed my hand from the jar. All due care was taken to prevent me breathing any of the vapour, and I sat during the experiment in a current of air. I felt the benumbing influence of the acid extending from the hand upwards along the arm a minute or two before the experiment was stopped.

In addition to the liquids and vapours experimented upon, I have tried long immersion of the hand in various gases, as carbonic acid and common coal gas, (both of them powerful general anæsthetics when inhaled,) without any effect. Chaptal, however, alleges that he had felt the limbs plunged in carbonic acid much benumbed; and Collard de Martigny* found that when the general surface of his body was immersed in carbonic acid, (arrangements being made so that none of it was breathed,) giddiness, ringing in the ears, and the other symptoms produced by the action of this gas supervened in eight or ten minutes, proving that it was absorbed. Davy† felt the premonitory exhilaration of nitrous oxide gas by exposing the surface of his body to it in the same way.

Chaussier‡ inclosed the leg of a dog in a bag containing sulphuretted hydrogen, and found that he could in this way, in a few minutes, induce the poisonous effects of this gas; and similar experiments were repeated by Lebkuchner§ and Nysten,‖ and my friend Dr. Madden,¶ on the rabbit, &c., with similar results. I have held my hand inclosed in a bag filled with the constantly renewed vapour of sulphuretted hydrogen for about half an hour, without feeling any local effects.

And even supposing that we could, by any means, so benumb the sensibility of a part to be operated upon as to render it anæsthetic, I doubt much if this state of local anæsthesia would place the parts in a condition at all favourable for being subjected to operation. It is quite possible, nay, probable, that other more powerful agents than those which I have experimented upon, may, by their local application, produce a greater and deeper local anæsthesia on the human subject than I have yet witnessed; but all, or almost all, of those that I have used, have, along with the anæsthesia, led to such a congested and injected condition of the part, as to give every likelihood, both of a greater tendency to hæmorrhage at the time of operating, and of a greater tendency to inflammation in it immediately afterwards.

Other and more simple agencies than any which I have mentioned are capable of producing a certain amount of local anæsthesia. A mere exposure of the hand, for instance, to great changes of temperature, either in the way of increase or of diminution, has the power of deadening the sensibility of the part. I have tried, and seen others try, to hold the hand, with a view to this, immersed in broken ice, or dipped in ice-water, and with the effect of inducing a degree of anæsthesia in the part, as deep as, if not deeper than, exposure of the same part for a greater length of time to the local action of chloroform would have effected. In his admirable and classical "Lectures on Inflammation," the late Dr. Thomson remarks, (p. 617,) that "the sensibility to external impressions of the parts exposed to cold, is always more or less impaired, and the diminution in the sensibility of the nervous system seems to admit of degrees, from the slightest perceptible numbness, to that of the most complete insensibility." But he also correctly adds—"This diminution, however, of the sensibility to external impressions, is not unfrequently accompanied with severe degrees of pain." In fact, in making the experiments to which I have above adverted with the pounded ice, few of us could allow the hand to be retained in it above two or three minutes, in consequence of the intense pain which ensued; but still that brief period produced, as I have said, a most distinct and well-marked degree of local anæsthesia.

Keeping the hand immersed in water, of as high a temperature as it can conveniently bear, has also the same effect of rendering it, in five or ten minutes, partially anæsthetic and benumbed, as compared with the other unexposed hand, and this without the pain and suffering connected with the other extreme of temperature.

It is not my object here to inquire in what relative diseased or other conditions of a part, heat or cold are respectively calculated to act anæsthetically. But I would beg to make strongly this general remark, that the action of the above, and other applications, which we use to inflamed, burned, neuralgic and pained surfaces and parts, (such as preparations of opium, conium, aconite, belladonna, tobacco, &c., &c.,) still require to be studied, which they have not yet been, in another and a new light,—viz., as LOCAL ANÆSTHETICS. Therapeutical writers will, I believe, perhaps betimes study and describe them in this novel point of view; and when attention comes to be directed to them with this object, some new facts and precepts may be elicited that will enable both the physician and surgeon to exhibit and apply local anæsthetics with more science, precision, and success, than hitherto.

The experiments and observations which I have detailed in the preceding pages, perhaps entitle us, in the present state of our knowledge, to draw the following

insane patient who broke his fibula, and continued to walk about without pain till the limb became inflamed and gangrenous. It was then amputated, and still without the patient suffering in any degree during the operation.

CONCLUSIONS :—

1. In animals belonging to the class of Articulata, complete local and limited anæsthesia can be produced by the local and limited application of the vapour or liquid of chloroform to individual parts of the body of the animal.

2. In Batrachian reptiles, the tail, or an individual limb, can be affected in the same way with local anæsthesia, by the local application of the chloroform; but, in addition, general anæsthesia of the animals usually results in a short time, in consequence of the chloroform absorbed by the exposed part coming to affect the general system.

3. In the smaller Mammalia a single limb, or even the whole lower or pelvic half of the body, can be rendered anæsthetic by local exposure of these parts to the influence of chloroform.

4. In the human subject partial, and, perhaps, superficial, local anæsthesia of a part, as the hand, can be produced by exposing it to the strong vapour of chloroform; but the resulting degree of this local anæsthesia is not sufficiently deep to allow the part to be cut or operated upon without pain.

5. Any agent possessing a stronger local benumbing, or an anæsthetic influence, would probably be dangerous, by its acting too powerfully on the general economy, before the local anæsthesia was established to a depth sufficient for operating.

6. Artificial local anæsthesia, from any known anæsthetic agents, seems objectionable in any part intended to be operated upon, in consequence of the vascular congestion and injection which attend upon and accompany this local anæsthesia.

7. There are few operations in which there is not previously a local broken surface; and the application of chloroform, &c., to such a surface, would be far too painful to be endured, no small degree of suffering sometimes arising from even the exposure of the unbroken skin to their action.

DR. FORBES IN REPLY TO MR. NEWNHAM ON THE PRESENT ASPECT OF MEDICINE.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,—I hope I am sufficiently tolerant of criticism to feel but little concern at anything depreciatory that may be said of my humble writings by the public press; and I am too careless and indolent to notice statements that merely relate to me personally. I would not, therefore, have troubled you or your readers with any remarks on the long paper of my friend Mr. Newnham, now brought (as I suppose,) to a conclusion in your pages, had I not felt, that by so doing, I might possibly, in some little measure, promote an object of professional importance. What I now propose to say, while it corrects some mistakes into which my friend has fallen, may have the effect of calling the attention of your readers, still more closely, to Mr. Newnham's excellent paper, and thereby aid the great cause which we have both so much at heart—the real advance of medical science and practice.

Of the numerous contributions and remarks, public and private, from personal friends and unknown critics, which have been called forth by the article commented on by Mr. Newnham, none has been, on the whole, so satisfactory to me as the paper in your Journal. Putting entirely aside the compliment implied in the fact of Mr. Newnham thinking the article of sufficient importance to call for so elaborate a commentary, I cannot help feeling particularly gratified to find a man of such long and extensive experience, and of such acknowledged talents—and, moreover, a general practitioner,—recording his concurrence in most of the views, both scientific and practical, contained in that much-discussed paper. And my gratification is not a little enhanced by the circumstance, that Mr. Newnham's concurrence in my opinion has been, as it were, forced upon him by the strength of his convictions—through the honesty of his nature and his paramount love of truth—in direct opposition to his obvious predilections and prejudices. My friend's first impressions on reading the article, were evidently unfavourable to my views; and he took up his pen in a hostile, or at least in an antagonistic spirit, to battle for what he deemed the truth imperilled, as he thought, in my unlucky pages. But Mr. Newnham is not the first man who, in combating a supposed heresy, has himself been converted, or who, on a holier occasion, having gone to scoff remained to pray. In making this statement, I am far from claiming the credit of converting my friend by my arguments: I am quite content with the honour of having supplied Mr. Newnham with *the occasion* of reviewing in his own mind, in a more particular manner, the results of his own observation and experience. The consequence to a man of his acuteness and candour, was inevitable.

It is indeed true that, while assenting wholly to several of my principal positions, Mr. Newnham only partially agrees with some, and dissents altogether from others; it will be found, however, that, even in regard to these latter, or at least to several of them, the difference between us is much widened, and in some cases entirely created, by a misapprehension on his part, of my meaning. In taking up my pen, I at first intended to restrict myself to the correction of some of these mistakes of my friend; but I now feel unwilling to let slip so favourable an opportunity of strengthening my cause, by the very effective, though unintentional aid of so doughty a champion as Mr. Newnham.

Mr. Newnham makes a strange mistake in confounding what is termed in the article, "The Natural History of Disease," with the plan or plans of *treatment* advocated in it. Nothing could be further from the truth than this; and I cannot see how Mr. Newnham could have made the mistake. Throughout the whole article, *the Natural History of Disease* is merely spoken of as a thing of essential importance to be known, with the view of regulating practice; but nowhere is it contemplated, much less recommended,

that any kind of rational treatment should be superseded by the process of mere observation or study of the phenomena of disease. This study is inculcated as of paramount importance for the attainment of rational practice—not as an equivalent or substitute for practice: to do so would be a palpable absurdity. Mr. Newnham states very accurately the views of the author of the article, when he says,—"If, by attracting attention to the natural history of disease, the prescriber may be alienated from an exclusive attachment to drugs, and can be led to a profounder study of regimenal and hygienic treatment, good must arise."

In like manner, Mr. Newnham seems to assume, throughout his paper, that the author of the article is an exclusive advocate of what has been termed *the expectant system*, in all its unmitigated severity,—that is, of a system which leaves nature, in the cure of diseases, entirely to her own resources. This is an equally great, if not precisely the same, mistake, and one which assuredly finds no sanction in the article in question; on the contrary, the only form of *expectation* contemplated in any case, when contemplated at all, was that form of it inculcated by STAHL, in the curious little work in which he criticised *Gideon Harvey*, entitled, "Ars sanandi *cum* Expectatione, opposita Arti sanandi nuda Expectatione,"—a system which, so far from leaving things entirely to nature, authorises and inculcates the employment of all therapeutical measures, medicinal as well as regimenal, energetic as well as mild, whenever and wherever *a proper indication* exists; and only advises non-interference in the very rare case where no such indication can be found, and in which neither reason nor experience can suggest aught that promises advantage to the patient: and, in truth, Mr. Newnham himself seems inclined to go as far in this direction as the author of the article. His description of *the expectation* here put hypothetically as what he could sanction, is precisely that entertained by myself, and, as far as I know, by all those who profess to follow Hippocrates, Stahl, Sydenham, or others who have professed and practised a *rational expectation*. "If by *expectation*," says Mr. Newnham, "be really intended *observation*, on the course of the malady, and supplying the proper remedies which such watchfulness may indicate, only in such order, and in such doses, as shall most safely lead to the convalescence of the patient,—accomplishing this object by the mildest known efficacious remedies, and attending diligently to all the beneficial influences which may be conveyed through the moral nature of man, as well as to all similar impressions conveyed by attention to diet and regimen, and air and quiet, and the general proper management of a sick room, why, this is only to abstain from that which would be a positive hinderance to nature's agencies, and here we go hand in hand with our expectant physician."—(p. 200.)* And Mr. Newnham's concurrence in this rational and praiseworthy abstinence in treating disease, is declared in almost every page of his paper.

As such sound doctrines cannot be too much impressed upon the minds of practitioners, especially the younger members of the class of general practitioners, I hope you will allow me to transcribe, in this place, a few more of my friend's statements bearing on this point. I shall set them down just as they catch my eye, and without particular comment. "We shall admit the *vis medicatrix naturæ*;—we shall admit that nature ever tries to restore all manner of lesions in her economy;—and we shall admit that it is folly and madness to contravene her efforts."—p. 198. "So again, of specific disorders—measles for instance; this must run a definite course, and if it be a mild case, it does as well under the marigold tea of the old woman, the handmaid of nature, as it does under the influence of more powerful articles of the Materia Medica."—*Ib.* "We cheerfully admit that the greater number of acute maladies pass of themselves through successive periods of incubation, gradual development, highest degree of intensity, decline and convalescence, without the employment of active remedies."—p. 199. "It is perfectly true that medical persons often gain credit for cases which nature has performed."—p. 253, &c., &c., &c.

The following extracts place in a very satisfactory light Mr. Newnham's coincidence with the views of the author of the article, respecting the use and abuse of drugs:—

"It is equally the fact that medical men, as they become older, become more distrustful of results; the enthusiasm of their early years is abated, and they become less 'heroic' in their prescriptions, more trustful of nature, less confident in themselves."—*Ib.* "We are fully disposed to admit that the treatment of disorder by medicine is often inefficacious and sometimes injurious; nay, we may believe with Dr. Forbes, that the rapid cure of some patients under hydropathic or analogous treatment, may depend upon their abandonment of injurious medicine."—p. 255. "We are not prepared to say that much of the practice in the present day is not mere guess-work, especially with those who see their patients perhaps but once, or, at all events, at very distant intervals."—p. 282. "We dislike polypharmacy as much as it is possible, and we would never exhibit a remedy of any kind unless we had a scientific reason for so doing."—*Ib.* "We quite agree with our author that much good may be done by abandoning the heroic method of treatment, provided that it be not supplanted by that system of negative expectancy, &c."—p. 283. "We believe that mischief perpetually arises from administering powerful remedies in large doses; we believe that irreparable evils accrue from the uncalled for exhibition of purgatives; and that much injury is occasioned by this perturbing system, by this thoughtless administration of drastic poisons."—p. 282. "There are great errors in the present day, and in the present style of prescription; and much as we abhor the system of being paid for medicine, much as we think it odious and intolerable, there are advantages in this system which

* "But this (Mr. Newnham adds,) "will not satisfy him, because this would involve the employment of every remedy calculated to favour our object, and assist nature in the accomplishment of her views, and assuredly this would be to interfere, with the natural history of disease,"—as if any sane physician would hesitate to interfere, where he saw room for interference, merely that he might study the disease!

are forfeited by others."—p. 283. "One word upon *mercury*. We believe that the use of this remedy is often inordinate—often misplaced—often mischievous. We have been saturated *usque ad nauseam*, by the public and by medical consultants, with the reference of every form of gastric and intestinal malady to bilious derangement; and that too, as a direct consequence of some primary irritation of the liver. We have been grieved with the eternal and mischief-making prescription of calomel and blue pill, and grey powder, for ever and aye, where mercury in every form should have been religiously withheld."—*Ib.* "We are quite willing to admit that, in general, we may be too little attentive to diet, regimen, &c., and that medicine loses much of its power by being deprived of the aid thus afforded."—p. 284. "Most devoutly do we wish for the day when all medical practitioners shall be paid for their time and talents, and not by the amount of medicine which has been exhibited."—p. 184, &c., &c., &c.

Now, I flatter myself that, in these extracts, my friend Mr. Newnham, shows himself a worthy and vigorous son of "Young Physic;" and he will forgive me, on account of the motive, for thus placing some of his excellent opinions in closer contact than they exist in his paper. It is but justice to him, however, to state, that these admissions and confessions on his part, are, in the original paper, qualified, in many cases, by subsequent observations intended to show that the views of the writer of the article are different from his, Mr. Newnham's. He may therefore say, that, in one sense, the extracts are "garbled;" but I shall not quarrel with his doing so, so long as he admits his opinions to be as here recorded; and this I know he will not hesitate to do. Most of his subsequent qualifications (here omitted,) are founded on that misapprehension of my real views respecting the treatment of diseases, already referred to. For the fair but feeble exposition of these views I confidently refer to the article criticised; of their truth and justice, when taken with the qualifications that accompany them in the original, I am more and more convinced by every day's additional observation and experience; and, as I have already said, it is most gratifying to me to find that I may add Mr. Newnham to the long list of men of the first eminence in the profession, who have been pleased to express their approbation of them both publicly and privately. I am ready to admit that, owing to the hasty manner in which the article was written, and to the impossibility, for want of room, of developing, with equal fulness, all the parts of the subject, some passages in it, taken by themselves, may appear too strong, and a few may even seem to bear an interpretation quite different from that they were meant to convey. But the views there delivered, when fairly judged, I can neither retract nor qualify; and I take the liberty to say that they are such as no physician who has a proper estimate of his profession, need be ashamed to avow.

So much for the general subject of Mr. Newnhams's comments and animadversions: but before I conclude, you must allow me to occupy a little more of your space while I refer to some other passages in which he has as completely mistaken my meaning. As, however, these are chiefly of a personal character, and consequently less important, I shall notice them as briefly as possible.

Mr. Newnham, "while cheered to find that I am not a believer in homœopathy," is still very wroth with me for dealing so leniently with Hahnemann and his system. I am surprised that so experienced a controversialist as Mr. Newnham did not recollect, what he must be well aware of, that the antagonist who is candid and courteous with his opponents, is much more likely to meet with success in the combat, than one who misrepresents them, or refuses them every sort of merit. Had I been in any way a favourer of homœopathy as a system of doctrine or of practice, I should not have been made the object of so many printed attacks from the homœopathists themselves, on account of the article in question. Speaking of the circumstances on which Hahnemann says he originally founded his system, Mr. Newnham most strangely states that I "allow them all the force of facts," and consider them "as good evidence as what can be adduced in favour of any other medical doctrine." So far from this being the case, I formally deny in the article the truth of those circumstances altogether. I merely say that "we have no more right to reject the *evidence* supplied in its favour by its professors, than we have of rejecting any other *evidence*." Of course not: but then the evidence must be true evidence, and equally good on both sides; and this I deny, in regard to homœopathy, over and over again, in the same place.

Mr. Newnham further says, (p. 228,) "that Dr. Forbes admits the claim of the doctrines of homœopathy to be founded on grounds even superior to reason, experience, and experiment." Now, I most assuredly admit no such thing. At p. 232 of the article, I certainly say, "So far, it must be allowed, the doctrines of Hahnemann have either *a show* of reason in themselves, or, at least, *claim to be founded* on grounds even superior to reason, experience, and experiment." But it is one thing for a party to *claim* and another to have the claim admitted. Mr. Newnham might just as well say, that because I allow that he *claims* for mesmerism certain powers and privileges, therefore that I admit the reality of these powers and priveleges.

Many other portions of Mr. Newnham's account of my opinions respecting homœopathy are equally incorrect. He goes all along on the assumption, that, because I refuse to the crude inferences of mere *post-hoc* reasoners, the right to be regarded as fair evidence, much less as proof of the powers and virtues of many common drugs as commonly administered; and compare, *in this respect*, the case of homœopathy and ordinary medicine; that I therefore admit, *as a general truth*, that the evidence in favour of each is equal, and consequently, that we must either believe both, or reject both, *in toto;* and, as I attribute *all* the cures in homœopathy to nature, I must likewise attribute *all* the cures in ordinary practice to nature also! Nothing is more unfair,—indeed, more absurd, than such an assumption. Any one who reads my article carefully will see that

I rigidly restrict my comparison with homœopathy to common blind routine practice, and do not at all extend it to rational or scientific practice; that I restrict it to the proceedings of the ignorant and ill educated, to the exclusion of those of the scientific, learned and judicious. In like manner I compared Hahnemann and his *system* with other theorists and systems,—with Paracelsus, Stahl, Silvius, Brown, &c., and their visionary theories; not with the men and the doctrines of the modern Hippocratic school of observation. An examination of my paper will shew that such alone was my meaning and intention, and numerous passages might be quoted from it to prove this. If this was not my intention, what could I mean by such passages as the following?—"We hold the great alleged fact from which the doctrine took its rise, to be no fact at all."—Art. p. 234. "We affirm that a large proportion of the experiments performed by Hahnemann and his friends, with the object of ascertaining the therapeutic properties of medicines, are altogether fallacies."—*Ib.* "In making these admissions in respect to the instances of treatment supplied by Drs. Fleischman and Henderson, we wish formally to guard ourselves against being supposed to admit, at the same time, as if it were one and the same thing, or as if one were a corollary of the other, that the result of the homœopathic treatment *generally*, is, and will be, as successful as the result of the ordinary treatment generally."—p. 250. "In doing so, [*i. e.*, adhering to the ordinary medical practice,] we consider that though we are embracing a system extremely imperfect, we are at least embracing one which, with all its faults, contains a considerable amount of truth, and a yet greater amount of good; and which, above all, is, or may be made, in its exercise, consonant with the principles of science, and is capable of indefinite improvement; while, in rejecting homœopathy, we consider that we are discarding what is, at once, false and bad—useless to the sufferer and degrading to the physician." p. 256—"From these our free confessions and bold denunciations of the feebleness and uncertainty of therapeutics, it may possibly be inferred, that we are entirely sceptical of the truth of medicine as a science, and think most meanly of it as a practical art. And yet this is not so; on the contrary, we look upon medicine, regarded in all its parts and bearings, as a noble aad glorious profession, even in its present most imperfect state, and we believe it destined to become as truly grand and glorious in actual performance, as it now is in its essence, its aims, and its aspirations."—p. 260. "In the hands of men of scientific education,—men of philosophical views and long experience, and who, from the position they occupy, and the confidence they inspire, are enabled to proceed exactly as they think best, PRACTICAL MEDICINE, we readily admit, is, even now, a rational and wise system, rarely productive of evil, if it fails to benefit, and often benefiting in the highest degree."—*Ib.* "Such as it is, our project of reform is, at the least, as conservative as radical. We are not altogether discontented with the general principles on which medicine, considered as a science, is now studied, by many men of education; we do not object greatly to the mode in which we know it to be exercised, as an art, by many of its professors; but we cannot shut our eyes to the enormous mass of its defects, &c."—p. 261.

There is only one other statement of Mr. Newnham's to which, before concluding, I must refer; but being one entirely personal, I shall notice it very briefly. Throughout his criticism, Mr. Newnham speaks of my article as if it were a separate work, calling it "the pamphlet," and asks, somewhat indignantly, "Why are *the public* invited to study this subject? Why are they tempted by alluring newspaper advertisements and a catch title, to dive into these hidden things?" Now, the fact is, that the article in question was never published at all, except in the pages of the *British and Foreign Medical Review*. A few copies were struck off separately, and sent to the author's personal friends, accompanied by a printed note, requesting them to favour him with any remarks that might occur to them; but not one copy was sold, or offered for sale. In all probability I sent a copy to Mr. Newnham, as one of my personal friends, and this he may have taken as evidence of separate publication.

I am, Sir,

Your obedient servant,

JOHN FORBES.

Old Burlington Street,
June 28, 1848.

CASE OF POISONING WITH ARSENITE OF COPPER; WITH REMARKS.

By JOHN M. BRYAN, Esq., Surgeon, Northampton.

On Wednesday, June 7th, at a public dinner, attended by about forty persons, Mr. William Cornfield, aged 62, with six or seven others, partook of some *blancmange*, coloured with emerald-green, among other eatables, at the New Hall at Northampton, the dinner being supplied by Mr. Franklin, confectioner of this town. According to the evidence of the widow, Mrs. Ann Cornfield, the deceased left home about half-past ten in the morning. He appeared quite well when he left. He returned home in an omnibus about half past six in the evening. He was very sick directly he came home; he had a little tea and a little brandy gruel after he was in bed. He also had some tea about one in the morning, and the sickness left him and he went to sleep. About four in the morning he awoke, having been asleep since one or apparently so, and said that although better he was still very bad; she went down stairs to procure him some tea, and was gone about twenty minutes, and on her return he was quite dead. No medical assistance was called in thinking it was only the different articles of food taken at the dinner that had caused his illness. He did not complain of any pain; when he returned home he said that the sickness was caused by some jelly or *blancmange* he had eaten at the dinner. He was perfectly sensible to the last. He had three motions after he came home and vomited five or six times. The first time the matter vomitted appeared very greasy, the second time it was rather yellow, and after the brandy it was darker. He

vomited about a quart, and said that he had vomited at the New Temperance Hall where he had dined. The dinner took place at four p.m.

Mr. John Faircloth stated at the inquest, that having seen deceased since his death, and having heard the evidence of the widow, he was unable without a *post-mortem* examination, to form an opinion as to the cause of death. The coroner then ordered a *post-mortem* examination to be made, and the jury requested Mr. John M. Bryan, surgeon, to assist in the examination.

Post-mortem appearances of Mr. Wm. Cornfield, deceased, seen by Mr. John M. Bryan, June 8th., twelve hours after death:—The membranes of the brain distended with serous and sanguineous fluid; numerous bloody points on slicing through the substance of the brain; the vessels much gorged with blood, and the ventricles full of serous fluid. The heart natural in substance, but containing much blood in a partially fluid state; the arch of the aorta unnaturally distended and granulated at the commencement; the lungs excessively gorged with blood. The liver natural or nearly so, but gorged with black grumous blood; the stomach very much inflamed on the entire internal surface, and some patches almost approaching to ulceration, the inflammation greatest towards the pyloric orifice; the duodenum very much inflamed, also the remaining portion of the intestines more or less, in their entire course, and containing a great deal of greenish pulpy matter; the spleen much gorged with blood; both kidneys extensively diseased, the right one granulated externally in the cortical part and the left one much disorganized; it contained a large calculus, apparently of phosphate of lime, (which was not, however, analysed,) of a crescentic form, nearly filling the pelvis of the kidney, which was otherwise distended with purulent matter; the bladder was small and thickened. Oblique inguinal hernia on both sides, easily reducible and of long standing. Diseased testicle on the left side, of scirrhous hardness.

Mr. Faircloth, in his examination at the adjourned inquest, after the *post-mortem*, said, "I made a *post-mortem* examination of Mr. Cornfield, yesterday, assisted by Mr. Bryan. On opening the head we found the brain very much congested and a great deal of effusion between the membranes; on cutting into its substance there was a great deal of fluid, serum, and blood; there was nothing further in the brain excepting bloody points, which we usually see in this congested state. We next examined the chest: the lungs were healthy but much congested with clotted blood; the heart was natural in size, gorged with fluid blood; evidently an enlarged state of the aorta, indeed very much enlarged; about the usual quantity of fluid in the pericardium or sac which contained the heart. We next examined the abdomen; the liver was natural but gorged with blood; the spleen the same. We then removed the stomach and the whole of the small intestines. The external coat of the stomach and small intestines was very much inflamed. We slit open the stomach and intestines throughout their entire length. The stomach contained a large quantity of fluid of a brownish green colour; the preponderance of colour being brown, with a tinge of green, the latter (green,) being most apparent in the small intestines, and in them there was a greenish pulp, a pint at least. The internal surface of the stomach was a good deal inflamed; the small intestines, particularly that portion that joins the stomach were highly inflamed indeed. The right kidney was enlarged and granulated; the left was smaller than usually found: on opening this it was full of matter. We also discovered a large calculus in the substance of the left kidney. We saw nothing further with respect to the kidneys. The bladder was smaller than usual; there appeared disease of the prostate gland. It may be right to mention that he was the subject of hernia on both sides, (a double hernia;) this was darker and harder than usual, and of a purple colour, which is found after the action of irritating substances in the system after death, in both sexes. All depending parts would appear darker than usual. Authorities on poison say so, but this had nothing to do with his death; it might occur in other cases, on the authority of Christison. We made no further examination. We find all these appearances arise from irritating substances received into the system. The aorta, knotty and enlarged, was a disease of long standing. He had suffered from pains in his chest, and difficulty of breathing. There was no rupture of any vessel that we could discover. The left kidney might in time have caused his death; would not cause immediate death. The internal coat of the stomach appeared to have received some injury. From the general appearances, I think, seeing the extent of disease that existed in the body, it is quite possible that any active or irritating substance received into the stomach might have accelerated death, but I cannot say that it was in consequence."

In answer to questions from the Jury:—

"I am not prepared to say that what he took at this dinner caused his death. I have no further conclusion to arrive at, as in the stomach no poison was found; I am not prepared to say that it was from it. My impression is, that the inflammatory appearance of the stomach might have caused his death; it was excessive. Wine could not have produced it. I did not observe any emerald green, and do not attach much consequence to the green appearance, which appears sometimes when other ingredients are taken. He had been vomiting all the evening. I am not prepared to say what quantity of emerald green would cause these appearances and symptoms. The effects of such a poison would have been very serious, the two ingredients or compound being very active poisons."

Mr. John Morgan Bryan, surgeon, said that he had paid particular attention to the evidence of Mr. Faircloth, with the whole of which he quite agreed, and had nothing to add.

In answer to questions from the Coroner:—The stomach and intestines were handed over to Mr. Greville, chemist, by him. The appearances in them were those which are seen after acrid poisonous substances. Did not think so much inflammation would be occasioned by other than poisonous substances. Considerable inflammation might be occasioned by the

habitual use of spirits, but the inflammation in this case appeared to have been very actively and suddenly produced, such as he has observed in other cases where poison has been detected.

In the examination of the stomach and intestines by Mr. Greville, Mr. Bryan saw the following results, not given in his evidence at the inquest :—

1st. A metallic crust by Marsh's test, and the proof by Guy's test or process, which consists in adding a drop of sulphide of ammonium on the crust which exhibited the yellow indication of sulphide of arsenic, without dissolving the whole of the crust. This would have exhibited very different results, had it been antimony, (the only other metal giving nearly the same appearances,) viz., the metallic crust would have been dissolved in a few seconds, and on drying would have exhibited the characteristic orange colour of the sulphuret of antimony.—(*Vide Pharmaceutical Times*, by Guy.) 2nd. The test for copper in a portion of the coloured part of the *blancmange*, viz., ammonia, giving the characteristic blue colour, forming the ammoniuret of copper, which is considered conclusive by Christison. 3rd. The arsenic sublimed from the emerald green, from a parcel of the same as was furnished to Mr. Franklin, the confectioner, by Mr. Barry, chemist and druggist, and which was tested with nitrate of silver, giving the characteristic yellow colour; and nothing else would have done so but the alkaline phosphates.

Mr. Henry Greville, chemist, examined :—"I was present at the *post-mortem* examination of Mr. Cornfield, and observed the high state of inflammation of the stomach and intestines. I had analysed the green portions of *blancmange*, and a very small portion adhering to the edge of the dish which held the *blancmange*. I was perfectly satisfied of the presence of copper, both in that and a portion of the green, no bigger than a pin's point, in the *blancmange*. I had no time to test so small a portion for arsenic, although I had reason to believe that it constituted a portion of the green colour. In order to satisfy myself as to the nature of the green, I obtained some of the emerald green from Mr. Barry, druggist, (who supplied the confectioner, Franklin,) and separated a considerable portion of white arsenic from it. From these preliminaries I was induced to test both for arsenic and copper in the contents of the stomach. I tested first for arsenic, and obtained, what I conceive to be, an arsenical result, but this was so very slight that I advance this very cautiously. I should be sorry to say that it was positively arsenic, although there is only one other metal which will give the same indications, and I could not test for antimony, the quantity being too small. I was then led to test for copper, but without any result."

In answer to questions by the Jury :—"The stomach had been considerably emptied, (after the dinner.) Arsenic attaches to the stomach, but the copper would be ejected. I tested the stomach for arsenic, and the small intestines only for copper. I had not time to test the stomach for copper. I examined the powder Smith the policeman brought down, (which was scraped off one of the shelves of the cupboard where the emerald green used by the confectioner was kept,) it was no more than could be scraped with a penknife from the end of the finger; it contained copper. I should think that ten or twelve grains of the powder Smith brought might cause death; and if that is the real arsenite of copper, or Scheele's green as it is called, it contains arsenic. Three grains of arsenic have caused death. In my own mind I have no doubt that the appearance of the stomach was occasioned by an irritant poison. It had all the appearances I have seen in such cases before."

The inquest was then adjourned, in order to afford Mr. Greville time to complete his analysis.

Mr. Henry Greville, chemist, (resumed.) "Since the last enquiry I have made a further analysis, chiefly with a view to ascertain whether there was copper in the stomach. I tested for copper and found no results. I then tested again for arsenic and found conclusive results; that (shewing a metallic stain on the handle of a white earthenware spoon,) produced is one. I again tested a minute portion of the green which I found upon the dish. I obtained arsenical results. At the request of Alderman Sharp I examined the white part of the *blancmange* and also some of the soup; no results from either. No doubt the sickness described by Mr. Cornfield and Mr. Betts, (one who dined at the hall,) would throw off a great portion of both copper and arsenic. In this case I could not detect the slightest trace of copper. It is possible that the whole might have been thrown off, especially as Mr. Cornfield had tea. That would not be the case with the arsenic which adheres to the coats of the stomach. The mineral green contains 47½ per cent. of white arsenic."

Cross-examined by Mr. Markham, attorney :—"It is not thought necessary to caution people in sending out colours."

By the Coroner :—"The green is composed of oxyde of copper and arsenic. The oxyde of copper is not, that I am aware, poisonous of itself, but when in connection with an acid becomes so immediately. In this case it is in combination with an acid,—with arsenious acid. The acidity of the stomach alone would be sufficient to render it poisonous. I cannot form the slightest idea what quantity of arsenic was taken into the stomach."

By the Jury :—"I should be very sorry to take ten grains of arsenic. I never knew emerald green to be used in confectionary until the present case; I have seen accounts of its being used. Christison mentions its being used in France. I should certainly object to supplying any person with emerald green if I knew it was to be used for jellies. Unless I was told I should take it for granted that it was to be used for colour. It would never enter my head that it was to be used for jellies."

By Mr. Pywell, attorney :—"If a confectioner's servant came to me for emerald green, I should be suspicious as to its use; but sending it out in the ordinary way, I should not label it."

Three witnesses, Messrs. Macguire, Groom, and Porter, were present at the dinner, and partook of the coloured *blancmange*, and were all sick about an hour

after, and had burning sensation in the throat and stomach. They were all told by the confectioner, Franklin, in answer as to what was the colouring matter in the *blancmange*,—"That it was nothing but essence of spinach, or spinach, which was also said by Franklin's assistant, Randall, whose peculiar department was to attend to, and make the sweets.

Charles Woolston, confectioner, (now in business for himself.)—Was in Mr. Franklin's service five years, and used the emerald green during that period; had occasion to fetch a pennyworth from Barry's, chemist, (it having been fetched previously by other individuals,) on his own head, who told him it was poison, and from that time has never used it in eatables. He told Mr. Franklin, and his assistant, Randall, too, that Mr. Barry said it was poison. Was with Mr. Franklin two years after that circumstance, and it was not used in anything whilst he was there but ornaments, which are not eaten, or intended to be eaten.

George Barry, witness, said:—"I am assistant to my father, and have served in the shop nearly seven years. I remember Randall coming several times for emerald green; other persons came as well. I cannot form any idea how often Randall used generally to come for a pennyworth. I have told him the nature of it. I believe I have told him on several occasions that it is of a poisonous nature, and must not be used on anything that is eatable. I don't remember that he made any remark on that. I don't remember cautioning the last witness, (Joseph Fousley, apprentice to Franklin.) I sent Mr. Greville some of the same emerald green from which I served Randall."

Mr. Faircloth, said:—"The appearances which we found on the *post-mortem* examination were such as would follow from arsenic, or some other powerful irritating poison. I cannot say that the inflammation was the sole cause of death. Deceased was greatly diseased; the large stone found in the kidney shows that his constitution was greatly disorganized; but I am unquestionably of opinion that death was accelerated by poison. I don't remember ever seeing so much inflammation where some irritant poison had not been introduced. The inflammation was of that character which satisfied me it had been suddenly produced; and the symptoms described by the other witnesses are such as would follow taking arsenic. Independently of the violent inflammation, the other appearances in the body were not sufficient to cause death at that time and manner, considering that there were no symptoms of illness."

By Mr. Pywell, attorney.—"I was Mr. Cornfield's regular medical attendant. I was not sent for on this occasion; he refused to allow his family to do so, thinking he should be better in the morning. The disease of one of the principal vessels connected with the heart will account for the poison acting so suddenly. Arsenic is known to act in a very direct manner on the blood."

Mr. Bryan, surgeon.—"I have heard the evidence of Messrs. Greville and Faircloth, and agree in the conclusions drawn by the latter as to the cause of death. I have no doubt the inflammation was produced by some irritant poison; I have no doubt of the presence of arsenic. A person so diseased as Mr. Cornfield, would be much more likely to sink under a smaller quantity of poison than a healthy person. I refer more particularly to the disease of the large vessel connected with the heart. I have no doubt that death was accelerated by the arsenite of copper."

Mr. Pywell, attorney for Mr. Franklin, said that Franklin had no further statement to make than he had already made,—viz., that he was ignorant of the poisonous nature of the green.

The Coroner then summed up. It was their duty first to satisfy themselves whether the deceased died of the poison in the *blancmange*; and, secondly, whether the person making it had used proper care and caution in making it. If they should be of opinion that due caution had not been used, then they would find a verdict of manslaughter.

The following verdict was returned:—"We find Mr. William Cornfield died on the 8th of June, from the effects of a poison called arsenite of copper, or emerald green, carelessly and negligently administered in a *blancmange*, made by Edward Randall, and carelessly and negligently sold by Edmund Franklin, with the full knowledge that it contained a deadly poison."

The Coroner said that was a verdict of manslaughter against both parties. They were committed to prison to await their trial at the next assizes, unless admitted to bail by a judge's order, which has subsequently taken place.

Remarks.

In this unfortunate case we could not but remark the almost entire freedom from pain, which is, however, observed by Christison to be the case at times after arsenic has been taken; but in the cases that have come under my own notice within these twenty years, there has been invariably constant pain until dissolution took place. There must have been an almost entire remission of symptoms to allow of sleep, for so long a time as from one until four in the morning. This case also tends to confirm what has before been noticed, how extensively the disorganization of such important organs as the kidneys may take place, and formation of large calculus, without manifesting any uneasy symptoms during life. I attended Mr. Cornfield myself some few years since, and have known him intimately up to the present time, and never heard him complain of any pain or uneasiness in the lumbar regions. It appears that some years since he was attended by Dr. Kerr, with symptoms of angina pectoris, which has manifested itself in a slight degree, at intervals, ever since, and which may be accounted for by the granulated state of the first portion or commencement of the aorta, although no osseous appearance of it or of the coronary arteries, was perceived at the *post-mortem*. His outward appearance was that of a robust healthy person, and the adipose tissue was three-quarters of an inch all over the parietes of the chest and abdomen. The omentum also was loaded with it, and the internal organs of the abdominal cavity generally.

CASES FROM PRIVATE PRACTICE.*

By John Richard Wardell, M.D., Edin.

Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

Case VIII.

Subclavian Aneurism.

On the morning of January 19th, 1846, when visiting a patient in the neighbourhood, I was requested to see John Armstrong, who was reported to be suffering from an acute rheumatic pain in the right shoulder. In the 65th year of age, and for his time of life, a fresh-looking man; complexion ruddy; volume of flesh good; appetite not in any degree impaired; regularly pursued his occupation, (being a repairer of the roads,) and with the exception of the previously-mentioned pain in the shoulder, to which he attributed but little importance, was in the enjoyment of wonted health. Upon interrogation, this pain in the shoulder had been experienced for many weeks, and he had applied to one or two irregular practitioners, by whom he had been bled, blistered, and plastered, but without deriving any benefit. The right hand was slightly swollen; he complained of a sensation of numbness, and thought it was not so strong as the other. He also said that near to the collar bone was "a small lump which fluttered and beat," after which statement I immediately introduced my hand beneath his shirt, and at once discovered an aneurismal tumour, the nature of which enlargement from the distinct pulsation, was readily recognized. It was about the size of the section of a small orange, and situated below the middle third of the clavicle. On a more careful examination, the anormal degree of pulsation extended further than was at first anticipated, as the vessel could be felt beating powerfully until lost behind the sterno-clavicular articulation; fremissement very perceptible; the right carotid artery beat with far greater force than the left, and on applying the stethoscope to the tumour, a distinct bruit could be heard isochronous with the second sound. By precise admeasurement its size was as follows:—From superior margin of pulsatory motion passing downwards and over its contour, $4\frac{1}{8}$ inches; horizontally, and as before exactly following its configuration, $3\frac{5}{8}$ inches; between the pulsating margin on the mesial side, and the sterno-clavicular articulation, was an indented-looking space measuring $1\frac{7}{8}$ inch. The clavicle could now be distinctly traced along the whole of its course; slight pulsating enlargement could be felt protruding upwards behind its superior edge. In the morning, the pains in the shoulder and arms were said to be less urgent than at night, and he confidently asserted that on rising in the morning the enlargement was of decidedly less dimensions. He was now warned of the very serious nature of the disease, whilst rest and a complete cessation from all employment were strictly enjoined. The bowels were to be kept open by gentle laxatives, all stimulating liquors to be avoided, and a spare farinaceous diet to be taken. The following mixture was then prescribed:—

R. Tinct. Digitalis, dr. iss.; Aquæ, oz. vj. Sit mist. Capt. oz. j., ter die.

January 28th. Tumour in all its physical conditions is the same.—Cont. mistura.

February 28th. Tumour seems somewhat larger since last report.

April 10th. Tumour has now to some extent protruded upwards behind the clavicle, and can also be felt pulsating lower down the thorax; space between the inner edge of the tumour and sterno-clavicular articulation nearly obliterated; pulsation, generally, as forcible, and bruit as distinct as ever. Cross bandages applied.

May 13th. The tumour gradually increases.

June 26th. The tumour has become considerably larger; clavicle cannot be traced further than about $1\frac{1}{2}$ inch from the sterno-clavicular articulation, where it then becomes lost in the swelling. Tumour measures $9\frac{3}{8}$ inches from above downwards, and $6\frac{1}{8}$ inches transversely; presents three distinct elevations on its surface, which are divided by well defined fossæ, thus giving to its external configuration that of a tri-nodulated swelling. Has become thinner of himself, and in the face looks somewhat bleached.

July 22nd. Tumour much larger, and reported to have increased more than usual during last week. Forearm of right side looks shrunk and wasted, and the skin is shrivelled; hand and fingers are swelled and turgid, and of a redder colour than natural. Complains of much pain in arm and shoulder; pulsation throughout entire surface of swelling distinct and powerful; bruit can still, though less audibly, be heard. Appetite good; bowels regular; radial pulse on affected side feeble.

August 5th. Called to visit him this evening, and he says that he has recently (during the last three or four days,) suffered considerably from pain in the arm and shoulder. Morbid enlargement now pointing, and conical prominence converges towards the sterno-clavicular articulation. On the apex of this ill-defined conical eminence is a light brownish purple ecchymosed patch, clearly circumscribed, and about the size of a crown-piece, while the contour of shoulder and upper arm look full, rounded, bright, and smooth, and on passing the hand over the surface of these parts, a feeling to the touch is given similar to that which is felt in a case of anasarca when the inferior extremities are in a state of considerable œdema. Colour throughout is redder than natural, and on superior surface of shoulder it acquires a roseate tint. Hand and fingers, as before, swelled, and redder than common. Appetite pretty good; tongue moist and clean; bowels regular; pulse in left arm of ordinary frequency. Says that swelling has felt larger to-day than it ever did on any previous occasion. Radial pulse in affected arm can, with great difficulty, be just distinguished. Tumour measures as follows:—

From superior pulsating margin which extends to supra-spino-scapular region on anterior part of thorax,	$10\frac{3}{8}$ inches.
Transverse direction,	$8\frac{3}{8}$ inches.
From sterno-clavicular articulation diagonally below axilla	$8\frac{1}{4}$ inches.

September 1st. During last week has been entirely confined to bed. Tumour has assumed a more even rotundity; looks larger; intersecting fossæ and nodulated eminences almost obliterated. Discolouration of integument has greatly increased, and this extends to several inches in circumference; it varies

* Continued from page 291.

from a livid brown to a dark crimsonish rose hue. Whole of shoulder and upper arm has a very congested œdematous appearance; hand and fingers as before. On the superior-posterior aspect of shoulder, especially over the superior scapular region, the surface is irregularly risen in dark phlegmonous patches, from 1 to 2 lines in elevation, which are of a rose-red shining appearance. Not the least pulsation can be felt in the radial artery of diseased arm. Complains of very much pain in shoulder and arm. On manipulation, tegumentary covering of tumour feels thickened and indurated, and a feeling is imparted as if there were infiltration of serum in the subcutaneous cellular tissue. Pulsation less distinct to fingers, but clearly to be heard either by stethoscopic or immediate auscultation; pulsation can now be distinguished for $12\frac{1}{4}$ inches from above downwards, for $10\frac{3}{8}$ inches transversely, and $10\frac{1}{2}$ inches diagonally from sterno-clavicular articulation towards the inferior part of the axilla. Bowels regular; appetite in some measure impaired; looks pale and emaciated, and says he is generally much weaker.

October 10th. Still confined to bed, laid on his back; countenance pale and sunken; general emaciation proceeded to a considerable degree; muscles are loose, wasted, and flabby; sleeps but indifferently, and often suddenly awakes, startled and intimidated; appetite much impaired. Tumour has become of an alarming size and appearance; integuments covering it much discoloured. In one place at the superior scapular region is a livid patch, of irregular rhomboid figure, from which there has recently been sero-purulent discharge, but this has now in a great measure ceased, and the place has become a dark brownish eschar-spot, slightly cracked, and imparts a roughness to the touch. Considerable anasarcal swelling extending over upper arm, axilla, and round to scapular region, the skin covering, which is bright and shining, and of a bright rose-purple blush; no pulsation at wrist; fingers and hand as before; lower arm much swollen; pulse in left arm weak and soft; tongue coated; bowels slow.

October 25th. Saturday evening. Last night very restless; tumour much the same as it had been during the few previous days. This afternoon, slight oozing of blood commenced, which has continued to increase, and is now slowly flowing from an ulcerated orifice on the superior aspect, near the sterno-clavicular articulation. Vital powers on the decline.

26th. Reported that bleeding continued up to the time of his death, which was at four o'clock this morning. The blood lost was of very considerable quantity, and it continued to ooze away during fourteen hours.*

* I regret very much to state that all entreaties were of no avail in urging the friends to allow an examination, as they were inflexible in their determination not to grant a *post-mortem*. I had taken careful admeasurements of the growth of the tumour, and considering that the example was one in which the progress and natural result of this affection were very obvious, I thus concluded that it might not be altogether unworthy a place in the series of cases now appearing in these columns.

27, Acacia Road, Regent's Park, London.

(To be continued.)

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF PROFESSOR SANDS COX, F.R.S., SENIOR SURGEON TO THE HOSPITAL.

Reported by PETER HINCKES BIRD, Resident Medical Officer.

CASE I.

FRACTURE OF THE NECK OF THE FEMUR.

Sarah Shaw, aged 57, housekeeper, was admitted into the Queen's Hospital on the 9th of April, 1846, under the care of Professor Cox. It is stated that she fell down upon the footpath, and struck the upper and outer part of the right thigh with great violence.

On examination the limb was found shortened, and the foot inclined outwards; there was free motion in all directions, but it was painful, more particularly when the knee was carried inwards. During these motions crepitus was distinctly felt; there was considerable swelling and ecchymosis, and the diagnosis was—fracture of the neck of the thigh bone without the capsular ligament. After a few days the limb was placed upon a double-incline plane, and she was discharged cured, walking but slightly lame, on the 15th of July, 1846.

REMARKS.

1. *A few observations upon the frequency of fracture of the neck of the thigh bone in old people.*—This species of fracture occurs much more frequently in women than in men, and the reasons of this are, the more horizontal position of the neck of the bone, and the greater feebleness of the female constitution.

The form of the femur is remarkably influenced by age, and this is one reason why old people are so much more prone to this accident than the young. The angle formed by the neck with the body approaches more to a right angle in the old subject than in the adult, and the length of the neck diminishes with advancing years, so that the head gradually sinks below the level of the trochanter major, and approaching the shaft in extreme old age, it even becomes contiguous. There is also another important change, and upon which the metamorphosis just mentioned depends. The neck of the thigh bone undergoes a process of interstitial absorption, the animal matter is taken away, and nothing remains save a thin brittle substance. From these changes we can easily understand how fractures of this kind so frequently occur in the aged; in the first, the weight of the body, or any force applied to the lower extremity, does not fall upon the axis of the neck, but acts with the advantage of a lever; in the second, the part is rendered weaker by the process of absorption, and of course less calculated to sustain even the weight of the trunk.

2. *Remarks upon the mode in which this accident is produced.*—This accident is frequently produced by sudden force applied to the neck of the thigh bone, as, when persons walking upon an elevated pavement, fall suddenly upon the road. A fall upon the trochanter

major, as in Shaw's case, is a frequent cause; but accidents much more trivial than these will often produce this fracture.

3. *The mode of distinguishing fracture without, and fracture within, the ligament.*—In this case it was not only important, but extremely interesting, to ascertain whether the fracture was within or without the capsular ligament; for, although the former may happen in early life, they both occur in age, and therefore no correct diagnosis can be made, but by the most careful examination. Fractures without the ligament are generally caused by accidents of a severe kind, as blows or falls, while those within occur from very slight causes; in the former also there is crepitus upon slight motion, and great ecchymosis attends it oftener than fracture within the capsule; there is also a greater degree of pain, and it is more tender to the touch.

4. *Some observations on the mode in which cure takes place; first, in fractures within the capsular ligament; second, in fractures external to the ligament.*—There can be no doubt that fractures of the neck of the femur within the capsule never unite by bone, but by ligament, and I shall now endeavour to prove the causes of failure in producing bony union; first, referring to mechanical difficulties; secondly, to certain conditions in the neck of the thigh bone, in old people more particularly, which seem to preclude the possibility of bony union, and also, that ill consequences would follow such an union.

To fractures in general, perfect co-aptation of the extremities of bone is of paramount importance; and the difficulty or almost impossibility of accomplishing this is held out as one great cause of non-union in fracture within the capsule; distension of the synovial membrane, with synovia, is said to be another cause; and another, is the comparatively isolated condition of that portion of the neck attached to the head of the bone from the circulating system.

Many contrivances and various kinds of splints have been invented to keep the bones in contact; but they are all almost useless, since they are inapplicable to the purpose intended, and, at the same time, injurious to an aged patient, who can but ill support long confinement in bed, extension, and pressure upon the limb. I do not see why distension of the synovial membrane should prevent the adjustment of the bones; but could these difficulties (as there can be no doubt that some exist,) be overcome, there still remain others of far greater importance, depending not upon mechanical, but upon certain vital conditions, which, as I have before mentioned, are connected even with the occurrence of the accident. These are the causes of non-ossific union, and by investigating these, the best method of treatment can be learnt.

The low condition of the reparative powers in advanced age, will undoubtedly counteract in a very powerful manner, bony union, and the condition of the bone itself shows how altered is the state of nutrition. It is weak, and liable to give way upon the slightest pressure, and therefore, it is not coaptation, on pressure, which can enable the part to restore itself. And in those parts of the osseous system which are surrounded by synovial membrane, and covered at their extremities by cartilage, there is an absence of the tissues which are connected with bones in every other situation, and play so important a part in their reparation when broken. From this it is evident, that the usual action which occurs in fractures generally, cannot take place here; and if it could, what would be the result if provisional callus was thrown out? Why, it would fill up the acetabulum, and so interfere with the structure of the joint, as entirely to destroy the natural actions of the limb. It appears as if it were ordained by nature that fractures within the ligament should not unite by bone, and this idea is strengthened by the fact, that fractures which occur external to the ligament unite by ossific deposit, and that within it there are not the structures necessary to produce provisional callus.

5. *The various modes of treatment applicable to each variety; the reasons why the double-incline plane was used in this instance.*—Various are the means which have been resorted to in treating fractures of the neck of the thigh bone within the ligament, for the purpose of producing bony union, and all without avail. Some use the double-incline plane; another method is to place a board at the foot of the bed, upon which the foot of the sound limb is supported, so as to prevent the descent of the body, and a weight is suspended to the other foot, and hung over the end of the bed, so as to keep up regular extension; another method is to bind both legs together, so as to make one limb preserve the extension of the other. The best method is to place a pillow under the whole extent of the limb, and to keep the patient very quiet till all inflammation and pain has subsided; then the patient should rise daily and sit in a chair, and afterwards walk with crutches until the ligament becomes thickened and the muscles increased in power.

In the treatment of the above case, the indication was to keep the bones in apposition, and no plan has been more successful than that adopted in this instance. The double-incline plane was used in order that the patient might lie in as easy a position as possible, to keep up easy and regular extension, and the strap around the pelvis was to press the trochanter towards the acetabulum.

I have lately seen the patient, and she follows her employment as housekeeper to a gentleman; and although it is a little shortened, she has a strong and useful limb.

In reference to this case, I am permitted by Professor Cox to insert an original letter from the late Sir A. Cooper, Bart.:—

"Hemel Hempstead, June 10, 1835.

"My dear Sir,—The fracture of the neck of the thigh bone within the capsule, which I call the internal fracture, certainly remains ununited by bone in a large proportion of cases, but as I have mentioned in my work on "Dislocations and Fractures of the Joints" there are a few exceptions to this rule, but they are very rare. One exception is, when the reflected ligament on the neck of the bone is not torn through, of which I have a beautiful specimen given me by Mr.

Swan, of Lincoln, and now of London, in which the neck of the bone had been cracked through, and twisted upon its axis; but it was not separated, and it is firmly united by bone, and it was curious that no surgical means were employed, and yet the cure took place in a very short time. In oblique fractures, in part within, and in part without, the capsular ligament, an ossific union will occur, but this is not truly an internal fracture. In young persons in which the limb was not shortened, and yet in which fracture was suspected, I should apply a pad to the hip, and support it by splints, and place the thighs over an inclined plane. But these are exceptions which rarely occur; it is the principle for which I contend, namely, that the fracture of the neck of the thigh bone, as it occurs in persons of advanced life, does not unite, and that attempts to make it do so, are useless in practice, and mistakes respecting the reparative process. In old persons the bone undergoes an interstitial absorption, which is the cause of the fracture of the cervix from slight injuries, and immediately after the accident the bone is drawn up, and widely separated from the other. This altered state of the neck of the bone from age, and the difference which exists in the articular extremities from the shafts of bones, in having no periosteum but only a reflected ligament, indisposes the bone to ossific union. In fractures of the shafts of bones, the muscles draw the fractured ends together, and the union is produced by the periosteum coating the bone with earth, as well as the cancelli forming new bone; but this is not the case in articular bones. For example, the patella has no periosteum, and that its natural mode of union is by ligament, is seen in experiments on dogs, hares, or rabbits, in which it uniformly unites by ligament, which nature knows is best calculated for motion; but the foolish surgeon squeezes down the bone, and uses complicated bandages to effect, in opposition to nature's wishes, an union by bone when his object ought to be only the production of a *short ligament*. The neck of the thigh bone is governed by the same laws. Nature's object is to produce a ligamentous union as being best calculated for future motion; and the surgeon, who is ignorant of nature's object, tries to effect an ossific union.

A base attempt has been made to fix upon me the opinion, that fracture of the neck of the thigh bone never united by bone; nothing is more false, for I have expressly in my work given the exceptions. Time is the only test of truth, and my professional brethren are now of opinion, that the union of the neck of the thigh bone, as a general principle, does not occur, and therefore are now giving up their absurd and even dangerous attempts. As to the specimens of union of the neck of the thigh bone in Paris, the French surgeons confound the internal with the external fracture. I have seen the museums of Paris and Germany, (1828 and 1830,) and they then did not contain any specimens of the kind, at least I did not see any, but they may have now one or two, as they will occur under the circumstances I have mentioned. You may do with this letter as you please.

"Believe me always, yours truly,

"ASTLEY COOPER.

"William Sands Cox, Esq."

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, JULY 12, 1848.

The pressure of important matter in our columns at this time, and the desire of giving a full report of the Branch meetings of the Provincial Medical and Surgical Association which have recently taken place, prevents our doing more than very briefly calling attention to a document which will be found in another part of the Journal. We allude to an address just issued by the Committee, on Poor-Law Medical Relief, which, as it appear to us, contains a temperate statement of the leading points of the question in its present aspect. In reference to this address, we may observe that a perusal of its contents cannot fail to shew the direction in which future exertions are to be made; and though the fast progressing session may not perhaps allow of any very sanguine expectations from legislative enactment during the present year, we may hope that the efforts which have been made to gain the ear of the Home Secretary and the head of the present Poor-Law Commission, will not be without beneficial results. As connected with the subject of the treatment to which the medical officers of unions are at present exposed, we would incidentally, and as briefly as possible, refer to Dr. Berncastle's case. In another column will be found the present state of the subscriptions to the testimonial intended to be offered to that gentleman. What form this testimonial is to take, we know not, but we feel it right to point out that, although defeated on a point of form, the real victory which Dr. Berncastle has achieved, in eliciting the strong opinion of the presiding Judge on the illegal conduct of coroners' juries, and the judicial direction as to the proper object of these rulers, both to Coroner and Jury, are most valuable, not only to the union medical officer, but to the whole profession. We are unable now to refer to the many instances in which coroners' juries have been in the habit of thus outstepping their lawful province, but we beg to remind the profession that Dr. Berncastle can only have obtained the expression of judicial opinion on their behalf by incurring a heavy expense, as the nature of the decision could not but leave him liable to his own costs in the action, and these are not likely to have been lessened by any chivalrous feelings in behalf of an oppressed individual acted upon, or experienced by, the gentlemen of the legal profession to whom the conducting of the case was intrusted.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

Continuation of Mr. Crompton's Digest of the Depositions on Burns and Scalds, made at Inquests held before James Chapman, Esq., Coroner for the Borough of Manchester.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death	Parts which were burnt.	How the accident occurred.	Remarks.
			1840				
125	F.	14 yrs.	Dec. 31	36 hrs.	All over except face	Fell asleep by the fire	Infirmary.
126	F.	7 yrs.	Nov. 28	41 days	Body & right arm	Blowing the fire. Parents at factory	Infirmary.
			1841				
127	M.	3 yrs.	Jan. 6	3½ hrs.	All over her body, except feet	Left with a sister seven years old. Mother lying dead in the house	Infirmary.
128	M.	3 yrs.	Jan. 9	12 hrs.	Ditto	Left in charge of a sister, aged seven, who had gone out	Infirmary.
129	F.	3¾ yrs.	Jan. 9	19 hrs.	Ditto	Left in charge of a sister, aged eight. Father out at work. Pinafore caught fire	Infirmary.
130	M.	4¼ yrs.	Jan. 11	56 hrs.	Ditto, except legs and feet	Left alone for a few minutes by a nurse. Had frequently been beaten for playing with fire	Infirmary.
131	F.	5 yrs.	Jan. 13	33 hrs.	Arms face breast and left side	Mother out. Her brother (younger than herself,) set her on fire while scaling the fire	Infirmary.
132	F.	6½ yrs.	Jan. 13	41 hrs.	Abdomen and thighs	Poking the fire. Had been left alone a few minutes	—
133	M.	3 yrs.	Jan. 13	2 days	Right side and arm, and side of head	Lighting a shaving. No one older in the house	Infirmary.
134	M.	3 yrs.	Jan. 6	24 hrs.	Head, neck, face, arms, & breast	Left in charge of a girl, aged 11	Infirmary.
			1840				
135	F.	47 yrs.	Nov. 20	61 days	Right arm, back and shoulder	Dress caught fire when she was supposed to have been drunk and asleep	Infirmary.
			1841				
136	M.	2½ yrs.	Jan. 7	16 days	Left arm, face and breast	Lighting straw. Three children (oldest 5 years,) left together	Dispensary.
137	F.	5½ yrs.	Jan. 25	20 hrs.	All over except legs and feet	Left to take care of two younger children. Parents out at work	Infirmary.
138	F.	28 yrs.	Jan. 30	5½ hrs.	Ditto	Fell asleep while sitting by the fire	Infirmary.
139	M.	4 yrs.	Feb. 6	6 days	Arms and face	Poker fell out of the fire upon him	—
140	M.	4½ yrs.	Feb. 18	2 days	Left side of face, neck, and left arm	Pan of boiling water tilted over upon him, whilst playing on the hearth	Linseed oil and lime-water
141	M.	3½ yrs.	Feb. 10	12 days	Slightly on left arm, and left side of face	Mother at work. Alone in her room. Grandmother below	Fits for two days before death.
142	F.	5 yrs.	Feb. 1	30 days	Arm, chin, neck, and breast	She and a child of eight years alone. Clothes caught fire in getting some soot to blacken Charles's face with	Infirmary.
143	M.	15 yrs.	Feb. 12	21 days	Both legs and right thigh severely scalded	Fell into boiling water	Infirmary.
144	M.	5 yrs.	Mar. 5	4 hrs.	All over his body except feet	Alone. Supposed to have been roasting a potato	Infirmary.
145	M.	5 yrs.	Feb. 23	20 days	Right side and arm	Alone. Mother and father gone in search of work	Infirmary.
146	F.	1 yr.	Jan. 30	18 hrs.	Belly, legs, left shoulder, and right arm	Mother laid her upon the hearth; there being no fender, a cinder is supposed, &c. &c.	Infirmary (out-patient.)
147	F.	7½ yrs.	Feb 2	17 hrs.	All over except face and legs	Petticoat caught. No one in the house except herself & another child	Infirmary.
148	F.	5¾ yrs.	Feb. 2	40 hrs.	Ditto	She and two other young children locked in the house by themselves	Infirmary.
149	M.	7 yrs.	Feb. 5	23 hrs.	Right side of face, right arm, throat & breast	Fell off his stool under the fire, when a cinder fell upon him. Mother out	Linseed oil and lime-water and flour.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the accident occurred.	Remarks.
150	F.	2 yrs.	Feb. 1	5 hrs.	Scalds of back, neck, and face	Mother gone into another room. In her absence, child, while stirring the fire, upset a pan of water	Dispensary, linseed oil and lime water.
151	M.	4¼ ys.	Feb. 9	6 hrs.	All over except feet	Pinafore caught in putting coal on the fire. No one in the house at the time	Infirmary.
152	F.	3¾ yrs.	Feb. 12	9 hrs.	Ditto	At a fire in a coal yard. No one near	Infirmary.
153	F.	8 yrs.	Mar. 27	4 days	Thighs, bottom of belly, shoulder, and right arm	Clothes set on fire by red hot poker. Her sister (aged 12,) had charge of her	Infirmary.
154	M.	5¾ yrs.	April 21	7 hrs.	Seemed to be roasted alive	Standing by the fire in his night dress. Mother up stairs.	——
155	F.	82 yrs.	April 22	Found dead	Head, arms, neck & body, burnt almost to a cinder	A person of private property, living in a house alone. Had been drinking gin and water by the fire side. House set on fire	——
156	F.	12 yrs.	April 26	15 hrs.	All over her body except face, breast, & feet	Sitting up for her master and mistress. Supposed to have fallen asleep with a lighted candle in her hand.	Infirmary.
157	F.	53 yrs.	May 3	16 hrs.	Ditto, except her hand, feet, and face	Bedridden. Left alone. Pulled a lighted candle over, and set fire to her bed	Infirmary.
158	F.	18 yrs.	May 9	38 hrs.	Ditto, except feet	A burning cinder supposed to have fallen upen her dress, while removing the ashes from beneath the kitchen fire.	Infirmary.
159	F.	60 yrs.	June 4	19 hrs.	Legs, thighs, lower part of belly & back	Not known how	Infirmary.
160	F.	3⅓ yrs.	June 1	7 days	From breast to the waist	Seated at tea table. Whilst her mother left the table she took up a cupful of hot tea, and upset it into her bosom	Infirmary (out-patient.)

Proceedings of Societies.

SUFFOLK BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

The Anniversary Meeting of this Branch was held at Bury St. Edmunds, on Friday, the 16th of June. The following members were present:—Dr. Hake, Dr. Probart, Mr. Image, Mr. C. C. Smith, Mr. Wing, and Mr. Kilner, Bury St. Edmunds; Mr. Crosse, and Dr. Ranking, Norwich; Dr. Durrant, and Mr. Bullen, Ipswich; Mr. Faircloth, and Mr. Peck, Newmarket; Mr. Humphry, Cambridge; Mr. Bree, Dr. Bedingfield, and Mr. Freeman, Stowmarket; Mr. Kent, Walsham; Mr. Ebden, Hawley; and the Rev. Mr. Donaldson and Mr. Herbert Bree, as visitors.

The Honorary Secretary, Mr. Bree, read letters of apology for non-attendance from Mr. Crowfoot, of Beccles, (retiring President;) Dr. Kirkman, Melton; Mr. Beales, Halesworth; Mr. Grouse, Hadleigh; Mr. Muriel, Wickham Market; Mr. Bartlett, Ipswich; and Mr. Locke, Debenham. He then called upon Dr. Hake, the President-Elect, to take the chair.

Dr. Hake, on taking the chair, addressed the meeting as follows:—He commenced by observing that Mr. Sibson had been invited to the meeting, in order that the members might have the advantage of witnessing that gentleman's method of physical diagnosis. In the year 1844, a paper of considerable length had been published in the "Transactions" of the Association, "On Changes in the situation of the Internal Organs," and had been characterized as a production second in importance only to the works of Laennec himself. Since the epoch of this publication, Mr. Sibson had been diligently engaged in the same pursuit, and had submitted his views to the public through the medium of various channels. It was a subject of regret that this gentleman was unable, from unavoidable circumstances, to accept the invitation of the Suffolk Branch. He had expressed his regret on the occasion and had kindly transmitted specimens of his full-sized drawings, together with directions for the use of his chest-measurer, which instruments were shewn to the members present. The chairman, impressed with the value and excellence of Mr. Sibson's labours, had thought it expedient to prepare a brief abstract of his more recent researches; and he hopod by so doing that he should assist in calling attention to methods

of diagnosis not fully known, but destined before long to occupy a large share of public attention. The number, originality, and accuracy of Mr. Sibson's researches, their easy application to the study of thoracic disease, the untiring diligence with which they had been pursued, entitled their author to the high distinction which he had attained, and to the gratitude of medical men. Mr. Sibson, in a paper entitled "On the Mechanism of Respiration," published in the "Philosophical Transactions," Part IV., 1846, demonstrates the comparative anatomy and physiology of the respiratory muscles. He shows that the snake has the most elementary form of ribs, attached only at their vertebral end, with neither sternum nor costal cartilages; and that when the lungs are expanded, the levatores costarum and external intercostals raise the ribs, widen the spaces between them, move their anterior ends forwards, and make the upper edge of one rib glide backwards in relation to the lower edge of the rib above it. He demonstrates that in birds, the sternum and sternal ribs, are coupled with the vertebral ribs and vertebræ, to complete the circuit of the chest. The respiratory movements, and the muscles exciting the movements of the sternal ribs on the sternum and on each other, are exactly the same in principle, though reversed in direction, with those of the vertebral ribs, on the vertebræ and on each other.

In mammalia, the addition of a large and efficient diaphragm (that in the bird being small,) modifies the form and varies the movements of the ribs and actions of the muscles in different parts. By virtue of certain anatomical arrangements, which are described, the ribs articulating with the superior curve of the dorsal arch, when raised, approach each other anteriorly. These ribs have a cartilage articulating with the sternum, which is analogous to the sternal ribs of birds. They comprise the *thoracic set*. The ribs that hinge on the inferior curve of the dorsal arch, when raised, recede from each other; they have floating cartilages, and are the *diaphragmatic set of ribs*, *Intermediate* are the longest ribs, connected with the dorsal arch; their cartilages are usually linked together, and articulate with the lower end of the sternum; they, when raised, usually recede slightly from each other. All the ribs recede slightly from each other behind. The anterior portions of the ribs move forwards and upwards, and carry with them the costal cartilages and sternum. The posterior portions of the ribs move backwards, push backwards the vertebræ, and deepen the dorsal arch.

After shewing that the external intercostals between the thoracic set of ribs are inspiratory; between their cartilages, expiratory; between the diaphragmatic set of ribs inspiratory behind, expiratory to the side and in front, and between their cartilages inspiratory; while between the intermediate set of ribs they are for the most part slightly inspiratory between the ribs, expiratory in front between the cartilages; after, also, showing that the internal intercostals of the thoracic ribs are expiratory behind and inspiratory in front if they approach there, and inspiratory between their costal cartilages; and that between the diaphragmatic and intermediate sets of ribs, and between their cartilages, they are expiratory throughout,—he proceeds to observe that the following muscles are inspiratory in addition to those above named:—

On a moderate inspiration, the levator anguli scapulæ and serratus posticus superior.

On a deep or difficult inspiration, the superior fibres of the trapezius; the sterno-cleido-mastoid; the sterno-hyoid and thyroid, with the genio-hyoid and digastricus; the pectoralis minor, and the lowest fibres of the pectoralis major.

And he further observes, that the following muscles are expiratory in addition to those named above:—

The latissimus dorsi; the lower fibres of the trapezius; the pectoralis major, and rhomboidei; (which combine probably with the latissimus dorsi and serratus magnus to draw the scapula down forcibly, and forwards on the ribs.) The recti; the external and internal oblique; the transversales and triangulares sterni; the sacro-lumbalis, and longissimus dorsi.

He concludes that the expiratory muscles are, combinedly, more powerful than the inspiratory.

In a more recent paper, (*Medical Gazette*, May 5, 1848,) Mr. Sibson applies his anatomical and physiological researches to the study of thoracic disease. He asserts with truth, that in the healthy robust man the well-formed chest has certain *prominences* and *depressions* indicating the organs underneath. The sternum is arched and is most prominent about the junction of the fourth and fifth costal cartilages, thence the lower end of it is either vertical or falls backwards; the upper third of the sternum is more prominent than the second costal cartilage to each side of it, while its lower two-thirds form a hollow between the third, fourth, and fifth costal cartilages of each side, which projects beyond the sternum between them, and from the two anterior pectoral prominences. The right thoracic prominence is in front of the middle lobe, while the left is in front of the exposed portion of the heart; the latter prominence projects more than the former.

A depression crosses each seventh and eighth costal cartilages, from the lower end of the sternum to the fifth intercostal space. These depressions are just below the thoracic prominences; the right depression exactly indicates the lower margin of the right lung, while the left depression indicates the lower boundary of the heart. The anterior surface of the chest just described is that of the true thorax, which contains the thoracic organs, and is formed in front by the five superior, or the thoracic set of ribs.

The right and left sixth, seventh, and eighth costal cartilages, which are in front of the liver and stomach, are conjoined, and branch off on each side from the lower end of the sternum, having between them the xiphoid cartilage and abdominal muscles. Their amount of prominence depends on the development of the abdominal viscera. If the liver be large, those of the right side may be most prominent; if the stomach be distended, those on the left.

Let the energies of a robust man be lowered by illness which confines him to bed, the amount of air

in the lungs, and blood in the heart, is diminished; these organs are reduced in size, and the prominences described above disappear.

When the abdomen is distended from flatus or ascites, so that the diaphragm is pushed upwards, and can descend but very partially during inspiration, the sixth, seventh, and eighth cartilages and ribs project, both in front and sideways, to a considerable extent. The projections of the third, fourth, and fifth costal cartilages disappear; the lower boundary of the heart, and lower margin of the right lung, are pushed upwards, sometimes as high as the fourth costal cartilage; both sides of the chest are flattened, especially the left. This is owing to the non-descent of the heart during inspiration, and consequently of the lung in its anterior and upper portion, over which inspiratory expansion is lessened; percussion is duller, and respiratory sound feebler, than on the right side, although no disease exists in the left lung.

If the liver be unusally large or adherent, so as to prevent the descent of the diaphragm on the right side, then the expansion of the right lung by the fourth, fifth, and sixth ribs is impeded; but not so the upper lobe, to the same extent.

Every chest disease stamps upon the walls of the chest *some characteristic peculiarity of form.*

In the emphysema of adult life, when the sternum and ribs are unyielding, the whole chest becomes globular, and enlarged everywhere to the utmost; in that of youth the sternum is remarkably arched and prominent at the centre, and falls in towards the lower end.

In phthisis, if there be a cavity, or scattered and acute tubercles in the upper lobe, the second and third ribs are flattened on the affected side. If there be diffused consolidation, with increase of bulk of the upper lobe, the second and third ribs are more prominent than in the healthy lung.

If from pneumonia one lower lobe is consolidated, the chest over it is enlarged; so on the opposite side, there is enlargement owing to exaggerated respiration there.

The writer proceeds on the same principles to characterize the displacement of surrounding organs from distension by fluid of the pericardial sac; and to describe the appearances of the surface which mark enlargement and adhesions of the heart; and concludes his important remarks by giving detailed explanations of the displacement of the viscera, both by means of the respiratory movements, and the alterations in bulk of diseased organs. The reader is, however, referred to the original papers for further details.

In a preceding paper in the *Gazette*, (April 7, 1848,) "On the Position of the Internal Organs during a Deep Inspiration, in relation to Pathology and Diagnosis," the same writer puts forth the following remarkable statement, and upon it no doubt he has based the application of the chest-measurer, which promises important results, a sample of which has been recently submitted to the Medico-Chirurgical Society of London:—"If any portion of the lung be diseased, the function of that portion will be diminished or destroyed, and the respiratory movements over that portion will be lessened, obliterated, or reversed. If we know the exact healthy movements of respiration, we can readily detect any change in those movements. Where we find the motion deficient, there we look for disease."

MULBERRY CALCULUS.

Mr. Bullen, of Ipswich, exhibited a calculus, (mulberry,) weighing seven ounces, which he had extracted from the bladder of a female child, aged 14. The case has already been detailed in the Journal. Mr. Bullen reported that the child recovered without any bad symptom, and was now quite well, with the exception of a certain degree of incontinence of urine, which usually follows this affection in the female. Mr. Bullen also detailed minutely the different stages of the operation in this extremely interesting and unique case. The stone was crushed by the forceps into seven or eight fragments, which were fortunately so well preserved that the specimen was perfectly restored.

Mr. Crosse hoped Mr. Bullen would permit him to have casts taken from the calculus. He had no doubt but that the case was unique in the annals of surgery. Supposing that the stone was formed immediately after birth, it gave half an ounce increase in the year, which was larger than any case with which he was acquainted.

An interesting discussion followed upon the difficulty which must sometimes attend the crushing of calculi in these cases, in which Mr. Crosse, Dr. Bedingfield, and Mr. Humphry, took part. Mr. Crosse had no doubt about the correctness of the practice of crushing in these cases. The meeting bore testimony to the ability and skill of Mr. Bullen in the management of the case.

COMPOUND FRACTURE AND DISLOCATION OF THE ASTRAGALUS.

Mr. Faircloth detailed the following case of this accident:—

Ephraim Scott, a lad in a racing stable at Newmarket, of ordinary stature, quiet disposition, with brown hair and eyes, aged 14 years, had always enjoyed good health, and had had no serious illness except measles. Saturday, May 3rd, was riding a young and vicious horse in the paddock; the animal reared until it over-balanced itself, and fell back rolling over on its right side. The boy came down on his right side, shoulder and hip; his right leg extended forwards, received the horses neck across the knee, whilst the left still entangled in the stirrup, projected backwards and under the horses right flank and hip. Except as regarded this limb, he escaped with a few trifling bruises, but the left ankle presented the following appearance:— Before the shoe-lace and the stocking were removed, a large projection on the outer side of the joint and some arterial oozing; when uncovered, the bones were seen projecting through a semilunar wound, at least four inches long. The astragalus was dislocated from its connection with the os calcis, and this articulating surface turned outwards through the lips of the wound. The bone was not separated from its attachments to the tibia and fibula, nor from the scaphoid anteriorly, but

to allow the bone to turn half round as above described the neck had given way transversely. Both the anterior portion of bone, which remained *in situ*, attached to the scaphoid, and the other larger portion were chipped or broken more or less.

Treatment.—After a very careful examination of the parts, the foot, the vessels, and the boy's state generally, it was resolved to try and save the limb. The dislocated portion of the astragalus, (amounting to four fifths of the whole of that bone,) was carefully detached from the tibia and fibula and these bones let down upon the calcis. The edges of the wound were brought together with three or four stitches and plaster, a compress of lint was placed over them, covered with oiled silk, confined with a turn or two of the bandage, and the whole secured in Macintyre's splint. During the first week he suffered from irritative fever, but much less so than might have been anticipated. He took salines and aperients, &c., as required. There was very little oozing of blood after the first few hours, but synovia was discharged in considerable quantities. The treatment was persevered in, the wound being dressed still with dry lint under oiled silk, as often as necessary until about fourteen days, and the splint itself was of course re-applied. This was done continually until about seven weeks from the date of the accident, when it was discarded, and an inside wooden splint with a foot-piece substituted for it, and a bread poultice employed. At the expiration of another week this support was removed, the limb bandaged, (a pad of lint only, being used for dressing) and a stirrup of paste-board passed under the foot, and continued up either side of the leg. He now got up and walked about aided with crutches, the foot being supported in a sling. *Seven* days after this time he began to try and accustom himself to bear slightly on the foot. He soon left off one crutch and used a stick. The wound was touched with sulphate of copper from time to time, and only covered with lint.

November 6th. He now walks with a crutch and stick, when going any distance, and walks well. The ankle is almost motionless as regards flexion and extension.

April 10, 1848. Walks well with a stick, frequently without one; the limb is nearly an inch shorter than the opposite one. Flexion and extension movements of joint increase.

Mr. Image related a similar case, and a discussion arose about the propriety of removing the bone in these cases, which Mr. Image remarked was about an equally divided point in British surgery. He thought his case, which was fatal from sloughing and consequent irritation, fever, and prostration, would have had a better chance of recovery had the bone been removed.

Mr. Crosse was much pleased with Mr. Faircloth's interesting case. He thought that the result of injuries to the ankle-joint in country practice without amputation was most encouraging, and instanced the success of Dupuytren, which was most extraordinary.

SACCULATED VESICAL CALCULI.

Mr. Peck then related a case of "Sacculated Calculus of the Bladder," and exhibited the sac.

Autopsy of G. G., aged 84, thirty-eight hours after death. Body stout; abdomen covered with fat to the depth of two inches. On opening it, the arch of the colon was found adhering to its upper wall on the left side. On introducing a sound into the bladder, it struck audibly against a hard body. The bladder was removed and opened; in it were found two calculi, *loose*, oval in form, and flattened, one weighing five drachms eight grains, the other four drachms forty-four grains; they were about the size of small pigeons' eggs, rough, but with the more prominent asperities slightly rubbed down, each with a small spot, where they had apparently lain, the one upon the other; at the apex of one was a small conical projection, apparently a fresh deposit. The coats of the bladder were thickened, and covered with muco-purulent matter; the vessels congested. The third lobe of the prostate gland was slightly enlarged. On the right side of the fundus of the bladder was found a pouch, formed by a protrusion of the mucous coat of the bladder through the muscular fasciculi, capable of containing about an ounce of fluid; it was empty, with the exception of some muco-purulent matter.

In the year 1836, the subject of this notice received an injury which obliged him to keep his bed some time. After this symptoms of stone appeared, and in 1840 a stone was ascertained to be present. In 1841 he began to drink the Vichy water, since which the symptoms almost disappeared, till he was attacked, a fortnight since, with pneumonia, accompanied with violent and distressing cough, which he aggravated by making most violent straining efforts. Upon this the stone symptoms returned, and did not leave him till he died, which he did from exhaustion, on the 25th of February, 1848. Connecting the history of this case with the *post-mortem* appearances, we are led to infer, that soon after his drinking the Vichy water, the calculi became encysted, and that they were forced out again into the bladder by the violence of the cough. Had these calculi continued till the time of death, and no *post-mortem* inspection been obtained, the Vichy water would have had, doubtless, the credit of having cured a severe case of stone; in fact, till the re-appearance of the symptoms of stone, it had, in this case, enjoyed that credit.

Mr. Humphrey read a valuable paper, entitled "Observations upon Anæsthetic Agents in Surgical Operations," which will be published in a future number of the Journal.

DISLOCATION OF THE HEAD OF THE FEMUR ON THE DORSUM ILII, IN A CHILD AGED THREE YEARS AND A HALF.

Mr. Image then detailed the following rare and valuable case:—

William Colley, aged 3½ years, of Ixworth, Suffolk, was admitted into the Suffolk Hospital, May 6th, 1847, with dislocation of the head of the femur on the dorsum ilii. The accident had occurred twelve days prior to his admission.

The accident appears to have been produced by his sister jumping upon his shoulders, from a step above

that on which her brother was standing. When I first saw him the left great toe was resting on the instep of the opposite foot, and the knee crossing over the lower third of the right femur. The limb was an inch and three quarters shorter than the right. He was a remarkably fine healthy child. Soon after his admission reduction was attempted for a considerable time, but unsuccessfully, as we were not able to fix the knee-strap sufficiently tight to bear the long continued extension.

May 7th. Having obtained a proper sized knee-strap, and having nauseated our little patient with tartar emetic, and put him into a hot bath, we again applied the pullies, and after ten minutes succeeded in reducing the dislocation. The bone passed into its natural situation without the slightest jerk or sound. The limb now assumed exactly the same appearance as the other, the shortening being entirely removed. The thighs were kept tied together for a week, and on the 18th of May he walked out perfectly well.

I have ventured to lay the above case before the Society, in consequence of a charge having been urged against a neighbouring surgeon, of pretending to reduce a dislocation of the femur on the dorsum ilii, in a child only four years old, that child being a pauper and chargeable to the parish. It was agreed, and proved by authorities, that no such case was recorded, and therefore had not occurred, and that seven years' old was the earliest period at which this accident had taken place. On being referred to, I was rejoiced to have it in my power to lay before the proper authorities the above case, which was submitted to some leading surgeons in London, who admitted its perfect possibility, although it was considered to be a very rare occurrence.

SCIRRHOUS LYMPHATIC GLAND.

Mr. Bree, the Hon. Secretary, then detailed a case of "Schirrous Deposit," affecting primarily and solely the lymphatic gland of the right axilla, in a lady, aged 60. The tumour was seen by Sir B. Brodie and Mr. Aston Key, and removed by the latter gentleman.

The physical character of the tumour previous and subsequent to the operation, and its microscopical examination afterwards, left not the slightest doubt as to the nature of the affection.

Mr. Bree remarked upon the extreme rarity of this form of carcinoma, Scarpa having denied its occurrence, and only one case being recorded by Dr. Walsh, in his excellent work, which was quoted from a Dublin journal.

Mr. Humphry, of Cambridge, mentioned to Mr. Bree a case, (which he has obligingly forwarded for insertion in the Journal,) as somewhat analagous to his.

The following resolutions were then passed:—

Proposed by Dr. Ranking, seconded by Spencer Freeman, Esq.,

"That the place of meetieg of the Suffolk Branch of the Provincial Medical and Surgical Association, for 1849, be at Hadleigh, and that J. Growse, Esq., be requested to preside."

Proposed by J. G. Crosse, Esq., seconded by J. R. Peck, Esq.,

"That the names of the following gentleman be proposed to be added to the list of Members of the Council of the Association:—Dr. Skrimshire, Sudbury; Dr. B. Chevalier, Aspal; John Growse, Esq., Hadleigh; W. Worthington, Esq., Lowestofft; G. Sampson, Esq., Ipswich; Dr. Kirkman, Melton; G. Mayhew, Esq., Stradbrooke; Wm. Jeaffreson, Esq., Framlingham; Richard Jones, Esq., Woodbridge; Spencer Freeman, Esq., Stowmarket."

Proposed by Dr. Bedingfield, seconded by W. Kent, Esq.

"That the best thanks of this meeting be presented to those gentlemen who have read papers or cases."

Proposed by G. Bullen, Esq., seconded by W. E. Image, Esq.,

"That the best thanks of this meeting be presented to the Feoffees of the Guildhall for the use of the room for the purposes of this meeting."

Mr. Coe and Mr. Kilner, of Bury St. Edmunds, were elected members of the Association.

Thanks were voted to the Chairman and the Secretary.

THE DINNER.

About fourteen of the members dined together at the Angel Inn after the meeting. The chair was taken by Dr. Hake, supported right and left by the Rev. Mr. Donaldson, the Master of the Grammar School, Mr. Crosse, Dr. Probart, Dr. Ranking, &c., &c.

Foreign Department.

MEMOIR ON THE LOCALIZATION OF SKIN DISEASES.

By M. Baron.

(Translated for the Provincial Medical and Surgical Journal, from the Gazette Médicale, April 1847.)

SUMMARY OF THE AFFECTIONS OF THE SUDORIPAROUS APPARATUS.

The greater part of these maladies are acute, dependent upon a general morbid and febrile condition, which manifests itself most frequently a few days previous to the eruption. This coincidence of the disease of the sudorific organ with the general symptoms ought not to surprise us, when we reflect on the connection between the secretion of the sweat, and the great functions of the economy. The special local symptoms of the affections here in question consist in the presence of vesicles, either isolated, or in groups, preserving their vesicular character throughout the eruption, and leaving (except when the sweat-ducts have been implicated,) only a whitish spot, indicating a rupture of the epidermis, which had been raised to form the vesicle, or else succeeded, when inflammation of the ducts has existed, by a reddish yellow pellicle. Abundant perspirations commonly accompany those maladies, in which there is no inflammation of the

* Continued from page 329.

sudorific ducts. It is in young men and young people that one finds the following classes of affections:—

1st. Exaggeration of the secretion. (Abundant perspiration.)

2nd. Exaggeration of the secretion. (Drops of sweat under the epidermis, or under this membrane, and issuing through the broken sudoriferous canals, or through the dilatation of these canals. Miliary perspiration.)

3rd. The same little drops or dilations. (Sudamina.)

4th. Slight inflammation, or great congestion of the sudoriferous and sudoriparous organs, and capillary vessels. (Eruption of miliary fever; papulæ; vesicular eruptions, accompanying profuse perspirations; development of vesicles from local irritants.)

5th. Inflammation of the sudorific ducts. (Herpes.)

DISEASES OF THE APPARATUS WHICH SECRETES THE EPIDERMIS.

Pityriasis.—This disease is the first stage of an inflammatory affection of the blennogenic organs, (mucous follicles,) varying from simple congestion to slight inflammation. There results from it a more active secretion, an increase and great dryness of the product secreted, and hence furfuraceous desquamation. There is seldom any apparent functional re-action; frequently the symptoms indicate that the cutaneous organs *generally* participate in the affection. In some cases there is itching of the skin, with slight redness. When the disease occupies a region furnished with hair, one observes that the hairs appear much less firmly fixed, falling out of their own accord, or requiring a very slight force to remove them; in some cases their growth is impeded, peculiarities which are easily explained, when it is considered that the epidermis is continuous under the hairs, and contributes to their maintenance in the healthy state, and therefore that they become less firmly fixed when the cohesion of the epidermic layer is diminished. It would appear that the increased activity in the secretion of the epidermis renders that of the hair less energetic; no doubt this is owing to the re-action of the pityriasis on the chromatogenous apparatus, which explains the brownish or blackish colour sometimes accompanying this malady. It is thus that we may understand the pityriasis nigra, of which we shall speak hereafter.

Eczema is a degree of inflammation of the blennogenic organs, greater than that which constitues pityriasis. It is no longer a simple irritation, but an inflammation, sometimes very considerable, which causes the mixture of the epidermic material with a fluid, at first serous, then more reddish or more purulent as the inflammation becomes more intense. The formation of the epidermic layer is disturbed; instead of an epidermis which becomes dry slowly and gradually, as in the normal condition, we observe (when there is a large proportion of fluid produced by the inflammation) a serous, or sero-purulent exhalation. If the proportion of fluid is small, the epidermic layer is replaced by scales, at first very thin, which dry by degrees, and are formed by the epidermic material mixed with a greater or less quantity of sero-purulent fluid—a mixture which explains the variety in the colour and thickness of the scales. The more intense the inflammation, the more vitiated becomes the secretion; the proportion of the epidermic matter diminishes, that of the sero-purulent fluid is augmented; there is liquid exhalation and difficult desiccation.

On the other hand, when the inflammation is less, the fluid is more colourless and less abundant. It terminates by exhaling a quantity almost inappreciable; but if the scales become thinner and thinner and less yellow, they are renewed less quickly: then, in proportion as the inflammation yields, the epidermis gradually dies. For some time it remains a little thick and firm, and some white scales are thrown off, which indicates that the secretion has not yet entirely resumed its normal state. In some cases, after eczema, the epidermis remains dry for a short time—a dryness which is explained in the same manner as that which accompanies pityriasis, viz., by the existence of a slight degree of inflammation. It is not rare to see true pityriasis succeed eczema, and the insensible gradation between the two maladies is one proof of the identity of their situation.

It is difficult to imagine that in the great inflammation which accompanies ringworm, the neighbouring organs to those which secrete the epidermis do not suffer from their proximity, but very quickly the vascular layer becomes inflamed and congested; hence the redness extends sometimes to a great distance from the principal seat of the malady; and hence erythema and erysipelas develop themselves in some people round the patches of eczema. The lymphatic network becomes easily affected—a participation which is in accordance with the proportion and frequency of the affection in infants, women, and lymphatic people. Possibly an inflammation of the exhalant vessels contributes to the formation, in eczema, of a serous or sero-purulent liquid.

Eczematous inflammation propagates itself often to the neck of the hair-bulbs, which occasions the dropping out of the hair as in pityriasis. In certain cases the sebaceous follicles are implicated, and pustules form.

Irritation of the papillæ manifests itself by the itching and intense smarting which are sometimes met with in eczema. The variety of colours in this, as in pityriasis, is to be accounted for on the same grounds.

Psoriasis.—There are some cases in which we remark red patches, without prominence, covered with their scales, which are weaker and less adherent to the skin than in the other forms of this malady. These scales resemble those which are the product of a dried fluid; nevertheless there is often some moisture under them, but the skin is not dry and rough as in the other species of psoriasis: it preserves almost all its pliability. These kinds of psoriasis are very analogous to eczema, and in some cases difficult to distinguish. Pityriasis also presents a great resemblance to psoriasis. Recent cases of psoriasis offer the greatest analogy to pityriasis and eczema, indicating apparently that psoriasis is a more advanced stage of the two other affections. What tends to prove this is the fact,—

that we sometimes see psoriasis follow eczema, and very rarely eczema succeed psoriasis. The latter affection consists in a chronic inflammation, with induration of the blennogenic organs. Through the turgescence which results from these changes, we may explain the projection of the skin below the scales. The epidermic layer, on the contrary, as in pityriasis, is more dry than in the healthy state. It is owing to the more intense degree of the inflammation that psoriasis, more rarely than eczema, is complicated with other affections. The disease keeps to the organ primitively affected, and does not pass to others.

The sudoriparous and sudoriferous organs appear to suffer from a modification which contributes, without doubt, to the production of dryness of the skin. Probably the excitement of the blennogenic organs is prejudicial to that which is necessary, in the sudoriparous organs, for the secretion of the perspiration, and that the secretion is thereby diminished. Further, the indurated blennogenic organs, and also the thickened scales which cover the skin, compress the sweat-ducts, and hinder the secretion, and secretion of the sweat. The re-establishment of the latter function is generally so much the more difficult as the disease is chronic, because the sudoriparous organs, with less facility, resume their duties in proportion as the modification to which they have been submitted, is prolonged in the same manner as after pleurisy, the lung is rendered by so much the less permeable to air the longer it remains under the compression of the effusion. The return of the secretion and secretion of the sweat, is derived from the irritation of the secretive organs, and contributes to the recovery of the psoriasis, thus directing us in our line of treatment.

(To be continued.)

ON POOR-LAW MEDICAL RELIEF.

There is no part of the administration of the Poor Law in which the public are more interested than in the medical attendance on the sick. The larger part of the expenditure of the rates is incurred in the maintenance of the sick and their families; and it is obvious that not only humanity but economy requires that the sick poor man should have good and speedy medical aid, to enable him to return to work, and thus remove himself as quickly as possible from dependence on the general fund. There is no doubt that the majority of guardians and rate-payers think they have. by the appointment of their medical officers, secured good and speedy medical aid to the sick poor; and it is hoped and believed that in the majority of the unions and districts throughout the kingdom this is the case: but this result arises much more from the conscientious and humane feeling of the parish doctor than from the excellence of the arrangements made by the boards of guardians. Such is the nature of medical practice, that there never is, and never can be any regular market price for medical services—The peer and the cottager, if they have a broken leg, or an inflammation of the lungs, require the same attendance, the same medicines for their cure; yet they cannot by any possibility pay the same amount of remuneration. Thence it follows that different classes of society pay very different sums for the same services. Advantage has been taken of this want of a fixed scale, to arrange the salaries of parish doctors in an arbitrary way, without the slightest reference to the actual amount of labour, or to the expenses incurred—thus in the very sickly winter of 1847-8, there have been unions in which the whole payment of the doctor has not amounted to *threepence* per case: and in others, permanently, the amount does not exceed *sixpence* per case, the medical officer having to provide at his own expense the necessary drugs and applications. The general average of payment in country districts in the South of England is about *two shillings and sixpence* per case. In this state of matters one of two things must occur—either the poor are neglected, they are supplied with bad medicines, and the general amount of sickness and mortality is increased —or, what, it is hoped, is far more common, the doctor does justice to his pauper patient, and uses his best endeavours to get him well, but receives no remuneration for his exertions; and, even, in seasons of extraordinary sickness which various circumstances have rendered more common than formerly, he must suffer a pecuniary loss —hence a great and natural dissatisfaction. Surely it cannot be right that either of these alternatives should be inevitable—it cannot be right that a great and rich country like England should consent to receive the gratuitous labours of a class of men, far from rich, in an unremitting and highly responsible employment—it cannot be right that three millions of our fellow subjects, and those the most helpless, should be entrusted to the unpaid labours of any class of men, before whom so great a temptation is set to render imperfect and inefficient assistance. In every other transaction in life it is considered necessary to pay well in order to be well served; and the medical profession may indeed be proud of the confidence that is reposed in its members, when they are expected to perform an anxious and harassing duty with the slightest expectation of pecuniary reward. It would however be well for the public to consider whether the general rule would not here also be applicable; and whether a more liberal payment would not insure, in the long run, a more efficient and complete attendance on the sick, and thereby a diminution of charges for sick maintenance.

At present the real amount of responsibility of the medical officer is by no means great. It is true he may often incur great blame from a very trifling cause, or perhaps from no just cause; but he may be guilty of great neglect without its being known to his employers. This arises from the circumstance of boards of guardians, however much they may desire to insure good medical attendance to their poor, being unacquainted with medical science, and therefore being really unable to judge whether the amount and quality of the attendance rendered by their medical officer is at all equal to the occasion. In all other public departments in which medical services are required, there is a system of inspection by competent medical authorities, which is absolutely necessary to a proper supervision, and which would introduce a real responsibility if it were applied to the Poor-Law Medical System. This is so generally acknowledged, that the only objection that has been

offered to it, is the expense. Undoubtedly if a system of inspection were to be properly carried out, it must be properly paid for; but this expense would speedily prove a saving, if with other improvements, it *insured* to the labourer good and speedy attendance. Such a system of professional inspection is not only necessary to do justice to the poor: it is also necessary to insure justice to the medical officer, for the extent of his services, and the exactness with which he performs his duties can only be appreciated by persons who are thoroughly acquainted with medical science and practice.

It has been objected that the medical profession have the remedy in their own hands; that they need not continue to hold their appointments for which they are so badly paid, but may give them up to others who will be ready to take them. It is true that in many cases, however low the so-called remuneration may be fixed, there will frequently be found men with the necessary testimonials, prepared to take the appointments; but these men will, in their turn, reiterate the same complaints, and with the same reason, for the grievance will still remain, *an undue amount of labour, attended with much anxiety and personal risk, will be demanded for an insufficient recompence:* the natural result follows — unless an abiding sense of duty and self-respect animates the medical officer, harshness and neglect take the place of kindness and zeal. Is not this a natural, nay, a necessary result? And ought not the public to consider well whether they are blameless in allowing a system to go on, which occasionally deprives the poor helpless man of health, or wounds him in his tenderest feelings by the neglect of those who are dear to him—which occasionally increases the expense of maintenance of the poor, by allowing disease to go on unchecked for want of remedies —and which always produces deep and heartfelt dissatisfaction to the medical man, who feels that of all public servants he is the hardest worked and the least remunerated. These evils are great and real—they are felt only by the doctor and the pauper; but their consequences affect society generally. The remedy is simple and practicable. Let the parish doctor be really paid, let him, after a proper calculation of his expenses, have a modest overplus to compensate him for his skill, his time, his mental anxiety—but let him also be really responsible to persons competent to understand his functions; let a strict supervision insure a punctual performance of his duty: in short, act as in any other business and relation in life—let a liberal course of action be encouraged on both sides—from the Poor-Law authorities, a rate of payment which shall be no longer penurious and illusory—from the medical officer, a prompt and earnest attention to the combined interests of the pauper and the rate-payer.

Committee of Poor-Law Medical Convention.

PETROLEUM IN ASIATIC CHOLERA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,—My attention having been directed to the report of a meeting of the Medico-Botanical Society, at which Mr. Guthrie read a communication from Prince Woronzow, the Russian Commander-in-Chief in Circassia, detailing a new and successful plan of treating cholera with petroleum by Dr. Andreyeoski, "who found it successful even during the most extreme collapse," I am induced to forward you the inclosed letter, which I addressed to Sir Charles Napier, G.C.B., in September, 1846, by whose directions it was inserted in the Indian journals, and extensively circulated in the East.

It is most satisfactory to me that this remedy, in the hands of Dr. Andreyeoski, should have so fully realized the expectations I had formed of it. I shall therefore feel obliged by your reprinting my letter to Sir Charles Napier, hoping that by means of your valuable journal the knowledge of its good effects may become more extensively known to the profession.

I remain, Sir,
Your obedient Servant,
Bath, June 30, 1848. JAMES TUNSTALL.

A Letter to His Excellency, Sir Charles Napier, G.C.B., Governor of Scinde, on the virtues of Petroleum in Asiatic Cholera:—

Sir,—The alarming fatality that has attended the progress of the cholera morbus in the province under your Excellency's command, has induced me to trespass on your attention some remarks on the efficacy of the Indo-petroleum—a remedy of singular virtue, when the powers of life require an active and powerful stimulus.

The pretoleum is a natural product found in many parts of the East Indies, in Persia, and in the island of Barbadoes, in various states of purity. A drachm contains fifty-two grains of pure carbon, with eight of hydrogen; whilst an equal quantity of any other substance, which could be safely administered, contains but five grains of that elementary body.

Pure petroleum is the only known substance which contains carbon and hydrogen, without the admixture of any other elementary principle, which is not the case with the other bituminous products; its peculiar efficacy depends on this binary combination, its curative powers resulting from the chemical union with those principles on which the morbid action depends, by its elements entering into new arrangements with the elementary gases eliminated by disease.

It is a mild though effective stimulant, antispasmodic and antiseptic, acting in the same manner on the absorbent vessels as mercury, without its deleterious effects; it speedily permeates the whole system, so that its odour is perceptible in all the animal excretions. Asiatic cholera is a disease requiring (as I can testify from my own experience in London and Edinburgh,) the most active diffusible stimulants to support the flagging energies of life; it is also a disease attended with an alteration and decomposition of the vital fluids. The observations of the celebrated Dr. John Davy, and of other eminent practitioners, have demonstrated that the respired air of cholera patients contains a much smaller proportion of carbon (that element which is discharged from the system during healthy expiration,) than is sufficient for the proper purfication of the blood.

Now, in the petroleum, we have a medicine that acts primarily as a powerful stimulant, secondarily by supplying the system with its due proportion of carbon for excretion; while its effects being produced by means of

the absorbent system, it acts beneficially as an antiseptic, preserving the frame from the rapidly fatal effects of this horrible disease by evolving carbonic acid from the lungs.

I have seen the petroleum used extensively both locally and generally, and have never observed the slightest deleterious effects arise from its exhibition, even in comparatively large doses. I am induced to believe, from actual observation, that it is a most valuable diffusible stimulant, and that, were it freely employed in the Asiatic cholera, it would produce marked beneficial effects.

To you, then, Sir, I would address those observations, which would more properly be addressed to the medical officers under your command; hoping that, by your kind recommendation, they may be induced to give this medicine a fair trial.

The petroleum used in England is the petroleum (*Barbadense,*) which contains, according to Dr. Ure and Professor Farraday's analyses, in 100 parts, 85.5 of carbon, and 14.5 of hydrogren, and by the latter it is called hydro-carbon.

It is important to guard against the employment of petroleum or natural naphtha, containing any other elementary body than the two before mentioned. To prevent any error in this respect, perhaps it is necessary to state that the petroleum (*Barbadense,*) employed by practitioners in England, is a pure hydro-carbon; it will, therefore, be necessary carefully to analyse the native East India naphtha before it can be safely administered.

The form of exhibition I would recommend is the following:—Take the yolk of one egg, and amalgamate with it a tablespoonful of the petroleum, and to it add forty drops of the aromatic spirits of ammonia, filling a wine-glass with equal quantities of brandy and water; and this dose may be repeated according to the emergency of the case.

My only object in thus addressing you is a public one, hoping that the above suggestions may meet with your approbation, and that this powerful remedial agent may be fairly investigated by the medical officers under your Excellency's command,

I have the honour to subscribe myself, Sir,
Your Excellency's obedient Servant,
JAMES TUNSTALL, M.D.,
September 22, 1846. Bath General Hospital.

ON DR. CASTLE'S CASE OF SUPPOSED POISONING BY FOWLER'S SOLUTION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In the case reported in the last number of the Journal, by Dr. Castle, of Leeds, it is assumed, (rather too hastily, I think, though certainly not without a degree of hesitation,) that half an ounce of Fowler's Solution of arsenic taken in unknown doses during the period of three or four days, proved fatal. I do not deny the *possibility* of a poisonous effect *in a given case*, of such a dose, because we can put no limit to the varieties of idiosyncrasy; but in forming an opinion as to the cause of death, we should indeed find ourselves on dangerous ground, if we only inclined to the admission of what is in itself extremely improbable. I shall first attempt to prove, that in the case in question, it is *highly improbable* that arsenic was the cause of death; and secondly, suggest a few hints applicable to medical testimony regarding the cause of death in other cases.

1. The smallest fatal dose of arsenious acid on record, is six grains for an adult and four grains and a half for a child. (Christison.) In the case in question not more than two grains was taken, and that in divided doses, for three or four days, the acid being rendered possibly less inert by its union with potass. Therefore if the arsenic was fatal, it was fatal in a dose of one-third of the lowest poisonous dose on record, divided by the number of times in which it was administered; and supposing it administered (as is probable,) in four doses, each dose was only half a grain, or one twelfth of the smallest dose ever known to have proved fatal!

2. Two cases have come to my knowledge from which it appears that two drachms of the solution, (or one grain of arsenious acid,) taken by mistake within twenty-four hours, was not only not fatal, but almost or quite innoxious. One of these occurred in the practice of Mr. Girdwood, in which the medicine had "no detrimental effect." The other case occurred in a patient of my own, who took forty minims of Fowler's solution three times a day, for about a week, (a grain per diem,) with but slight inconvenience. Hence it is on two grounds highly improbable that half a grain per diem for four days should prove fatal.

And further, the fact that even this dose was taken in the case before us is founded upon "imperfect evidence." And surely we are not warranted in believing on such evidence, that a dose twelve times less than any fatal dose on record, and twice less than doses which have proved harmless, was really the cause of death.

But lastly, it must not be forgotten, that the *post-mortem* appearances in this case are excedingly common even where no suspicion of poison exists. Thousands of patients die of inflammation of the stomach and bowels, from various other causes. Nor is it certain that the patient in this case died in consequence of the condition of the abdominal viscera. How often does the *post-mortem* examination fail to detect *any* cause of death, proving that there are causes of death beyond the scrutiny of the scalpel, and independent of its discoveries. Are we not often too hasty in deciding that certain ambiguous appearances after death, reveal the cause of it, *merely* because there is no other evident cause?—a most fallacious conclusion surely!

The facts of this case are highly interesting, and Dr. Castle deserves our thanks for having placed them on record; yet, with all deference to his suspicions, it must be admitted that *they prove nothing.*

I hope shortly to be able to place before your readers a host of facts on the medicinal action of arsenic, which will present a cumulative argument towards establishing the safety of small doses of the mineral, which no one fact can in the slightest degree nullify.

I am Sir, your obedient servant,
THOMAS HUNT.
Herne Bay, July 1, 1848.

Medical Intelligence.

THE BERNCASTLE TESTIMONIAL.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,—Herewith I forward you a list of subscribers to the "Berncastle Testimonial" to the present date, with a request that you will insert it together with this note. I should be much obliged by receiving the subscriptions of those gentlemen who intend adding their names to the list at as early a period as possible, in order that the subscription may be closed.

I remain, Sir, your most obedient servant,
CHARLES WILSON STEEL.

Lewisham, June 27, 1848.

APPOINTMENTS.

On Thursday last, Frederick Carpenter Skey, Esq., Richard Anthony Stafford, Esq., and Bransby Blake Cooper, Esq., were elected Members of the Council of the Royal College of Surgeons, in the room of Messrs. Briggs, Liston, and Morgan, deceased.

Professor Syme has been allowed by the Crown to withdraw his resignation of the Chair of Clinical Surgery in the University of Edinburgh.

ROYAL COLLEGE OF PHYSICIANS.

The following gentlemen were admitted Fellows of the Royal College of Physicians, on Monday, June 26th:—Dr. Francis Boott, Gower Street; Dr. T. Bell Fletcher, Birmingham; Dr. Samuel J. Jeafferson, Warwick; Dr. Alfred Lochée, Canterbury; Dr. F. Weber, Norfolk Street; Dr. E. Lloyd Birkett, Cloak Lane; Dr. C. West, Wimpole Street; Dr. T. Blackhall, Queen Street; Dr. W. W. Gull; Dr. T. K. Chambers, Hill Street; Dr. H. Munro, Harley Street; Dr. G. E. Day, Upper Seymour Street.

UNIVERSITY OF CAMBRIDGE.

The following gentlemen received the degree of M.D., on Monday, July the 3rd:—Thomas Blackhall, Gonville and Caius College; Herbert Davies, Queen's College.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members, Friday, July 7th:—H. Parfitt; J. Rhodes; T. Taaffe; F. M. D. Davidson; P. Wright; L. Parnell; A. Butler; J. Lawrence.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, June 22nd:—Joseph Alfred Tapson, St. Germains, Cornwall; John Hendley; Frederic Hodson, Goole; Samuel Elevin Brand; Joseph Nash, Edenbridge, Kent; John Thomas Arlidge; Joseph Adolphus, Jamaica.

OBITUARY.

Died, June 23rd, at Warrington, aged 32, J. Stanton, Esq., Licentiate of the Royal College of Physicians, London.

June 23rd, at Launceston, aged 44, J. F. Smith, Esq., Surgeon.

June 26th, at Partry House, Mayo, of fever, aged 34, George Lynch, M.D., late Physician to the Fever Hospital, Ballinrobe,

BOOKS RECEIVED.

Insanity tested by Science, aad shown to be a Disease rarely connected with Permanent Organic Lesion of the Brain. By C. M. Burnett, M.D. London: Highley. 1848. 8vo. pp. 107.

TO CORRESPONDENTS.

Communications have been received from Mr. T. L. Walford; Mr. R. O. Johnston; Dr. Tunstall; Dr. E. D. Walker; Mr. Crompton; Mr. Bartrum; Mr. C. Vines; Dr. Thurnam; Dr. Oke; Dr. Coley; Dr. T. O. Ward; Dr. T. Thompson; Mr. Hatton.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

MEMOIR ON TURNING,

AS AN ALTERNATIVE FOR CRANIOTOMY AND THE LONG FORCEPS, IN DEFORMITY OF THE BRIM OF THE PELVIS, &c. &c.*

By J. Y. Simpson, M.D.,

Professor of Midwifery in the University of Edinburgh.

Section VII. (*Continued.*)—Physiological and Pathological Reasons for the Life of the Child not being necessarily compromised under the Proposed Practice.

We have already found, that when the child is extracted by turning through a contracted pelvic brim, its life is not necessarily sacrificed, (as has been alleged by some,)—either, 1st, by the injurious compression to which its head is consequently subjected; or, 2nd, by the degree of traction required to be made upon its neck.

One more special objection to the proposed operation of turning remains for our consideration, viz.:—

3. Is the Practice incompatible or not with the Safety And Life of the Child in consequence of the Compression of the Umbilical Cord?

In speaking of the propriety of delivery by turning in the class of cases for which I have proposed it, Dr. Radford states as an objection to it, the danger and death to the infant from pressure upon the funis, and consequent obstruction of the umbilical circulation. In footling presentations, "the funis, (he observes,) is subject to fatal compression;" and he imagines this danger must be greatly increased in cases in which the child has been turned, on account of distortion of the maternal pelvis.

Perhaps the proper and the most direct answer to this, as to the other objections to turning, drawn from supposed dangers to the child, is simply a reference to the actual results of the cases which I have already quoted, and may yet have occasion to quote in the sequel. In many of these the child will be found to have passed or been drawn footling through a contracted pelvis, and yet, in despite of the alleged fatal danger of compression of the funis between the body or head of the child, and the interior of the maternal passages, the infant *has* been born alive. The infant has been subjected to the alleged cause of danger and death without the alleged effects following; and hence we are surely entitled to conclude that the influence of the cause is not so likely to interfere with the operation of delivery, as has been theoretically presupposed.

Let me not be misunderstood. I by no means wish to argue that in turning in distorted pelvis there is no danger to the child from umbilical compression, for I believe quite the reverse; but I imagine, at the same time, that on first thinking over this undoubted source of danger, we are apt in our own minds to magnify its effects. Experience, as I have just now stated, teaches us that they are not so great as theory might lead us *a priori* to believe; and when we consider the subject for a moment, we shall find, I think, sufficient reason for seeing,—1st, that the risk and occurrence of umbilical compression in footling presentations and turning is not so very great as to invalidate the practice, and it is in part averted by the very form of distortion to which the pelvic brim is most usually subject; besides, supposing, 2nd, the compression to take place, there may still, I believe, be measures in the resources of science, by which, if we cannot now avert the occurrence of compression of the cord, we may prevent at least the more dangerous consequences of the complication for the child. I shall speak briefly of each of these points.

The Danger and Mortality from Compression of the Cord is not so great as to invalidate the Practice of Turning.—Dr. Churchill has published a table of 542 cases of turning in which the result to the child is mentioned. In these 542 cases 182 children were lost, or rather less than 1 in 3. And when we recollect that no doubt in many of these 182 cases the child was dead *before* turning was adopted, and that in others the cause demanding the delivery, such as presentation of the placenta, was the cause also of the infant's death, &c., we shall see reason to believe that the chance of death to the child from the compression of the cord would be found to be less than the chance of death from the application, and compression, and traction of the long forceps; for, even in the more

* Continued from page 176.

common form of delivery by the short forceps—an operation which is generally looked upon as less dangerous to the child than delivery by the long forceps—the mortality among the infants is as great or greater than from turning.

Out of 871 cases of delivery by the forceps, and almost always the short forceps, collected by Dr. Churchill, 175 children were lost, or 1 in every 5.

Out of twenty-four short forceps cases which occurred in the Dublin Hospital during Dr. Collins's mastership, eight of the children were still-born, or 1 in 3. Out of thirty-three cases of presentation of the shoulder or arm which he treated by turning, in two the child was putrid, and in two others there was hæmorrhage, in one of the unavoidable, and in the other, of the accidental form, and death of the children. Among the twenty-eight remaining cases nine were born dead, or nearly 1 in 3. Here, suppose we admit that the cause of death in these nine children was traceable to compression of the umbilical cord; still the infantile mortality was probably as little or indeed less than would be found to result from delivery with the long forceps.

Out of forty-two forceps cases related by Dr. Lee in his "Clinical Midwifery," in thirty-one cases the child was still-born, or 3 out of every 4 of the infants were lost. In thirty-nine instances in which he had recourse to turning in transverse presentation, twenty-nine of the infants were born dead, or about 3 out of every 4. His deliveries by the forceps were fatal to the children in 3 out of every 4 cases; and his deliveries by turning were fatal to the children in nearly the same proportion of 3 out of every 4 cases.

Out of ninety-three forceps cases related by Madame Lachapelle in her "Pratique des Accouchmens," in fifteen the children were still-born, or 1 in every 6 of the infants was lost. In sixty instances in which she had recourse to turning in transverse presentation, eleven of the infants were born dead or 1 in every $5\frac{1}{2}$. Her deliveries by the forceps were fatal to the children in the proportion of 1 in 6; her deliveries by turning were fatal also in a similar proportion, namely, about 1 in $5\frac{1}{2}$. Of ninety-six forceps cases occurring in the practice of Madame Boivin, (*Memorial de l'Art. des Accouchmens. Table, p.* 464,) in twenty the children were born dead, or 1 in every 5 of them was lost. In sixty-two cases in which she resorted to turning in transverse presentation, seven of the infants were still-born, or about 1 in 9 was lost.

To obtain with more certainty the general comparative average mortality of forceps cases and cases of turning in transverse presentation, let us combine the data above given from the practice of Collins, Lee, Lachapelle, and Boivin.

The following table exhibits in an abridged and simplified form, the results of this collection of cases:—

TABLE VII.

Comparative Mortality of Children in Cases of Delivery by the Forceps and by Turning in Transverse Presentation, in the practice of Collins, Lee, Lachapelle, and Boivin.

Mode of Delivery.	*No. of Cases.*	*No of Children still-born.*	*Proportion of Still-born Children.*
Forceps cases	255	74	1 in every 3 died
Turning in transverse presentation	194	58	1 in every $3\frac{1}{2}$ died

Arrangements and Means by which Compression of the Cord, in its Effects, may be averted.—Dr. Radford believes that when the child is extracted by turning on account of distortion of the maternal pelvis, the danger of fatal compression of the umbilical cord is then greatly increased by the fact of the distortion. But the common variety of contracted pelvis requiring turning is, (as I have already stated, and will insist upon more afterwards,) the peculiar and common kidney-shaped distortion of the pelvic brim, which is produced by the anterior prominence and projection of the sacral promontory. When the fœtal head enters it, as it does under extraction by turning, with its long or occipito-frontal diameter lying in the transverse diameter of the brim, then we have, [See *Fig.* 4, Journal for January 12,] a free space left of greater or less size between the face or forehead of the child, and the ilium to which it looks. In this space, sufficient room may certainly, in general, be found forthe free lodgement of the cord without injurious compression. The very narrowness of the conjugate diameter of the brim prevents this space being entirely filled up and encroached upon, by preventing the great mass and breadth of the head (from the coronal suture backwards,) from further passing over to this partially-occupied side of the pelvis. Besides, this uncompressed lateral space is the very site along, or near which the cord necessarily passes in descending from the uterus, and stretching between the placenta and umbilicus. For the anterior surface of the abdomen of the child to which the lower end of the cord is attached, always, of course, looks to that side of the pelvis to which the face is directed, and it is on that side that we have the free and uncompressed space I speak of, as fitted for the safe transit and lodgment of the cord. In thus stating the space as free and uncompressed, I mean in so far as the adjoining opposite surfaces of the child's head and interior of the pelvis are concerned. The space itself may be filled up, or the cord in it pressed upon by the circle of the cervix uteri or other soft parts; but certainly a little adjustment and management may often prevent any fatal compression from these sources. For the cord may be carried round by the accoucheur to that point in which there appears the greatest space, and consequently, the greatest freedom from compression,

and he may sometimes defend it from the pressure of the cervix by allowing it to pass between two fingers, introduced either for the sole purpose of protecting it, or with the view of simultaneously assisting the extraction of the head by applying some force to the cheeks or lower jaw. In both natural and artificial footling presentations it has even been proposed to defend the cord more methodically by shielding and enveloping it at the part liable to compression in a kind of special protecting instrument. Dr. Joos, of Schaffhausen, has ingeniously proposed an instrument for this purpose. (See *Medical Gazette*, Oct. 22, 1847.) It consists of a tube from four to eight inches in length, and of calibre sufficient to contain the umbilical cord, leaving a longitudinal slit or fissure equal to 1-12th of its circumference. It is composed of caoutchouc or leather, in which are embedded a series of steel rings three lines broad, and at the distance of one line from each other. The slit is opened up at one end by the finger, so as to admit the umbilical cord, and in the same manner it is made to receive it along its whole length, the fissure closing up as the finger is removed. A handle may be required subsequently to keep the instrument in its proper place. "The application of the instrument" (says Dr. Joos,) "takes place during the act of birth, by presentation of the breech or feet, in cases where delivery is effected by version and bringing down the feet, and in cases where the cord is prolapsed and cannot be returned." But I greatly doubt whether, even if we were provided with such an instrument, as Dr. Joos describes, we should not find the difficulties of applying it, and the time required for that purpose, more dangerous to the infant, than the extraction of the child's head by more simple and direct means. It is always well to avoid instruments when we can avoid them, and such an one as the present might not be used without some danger to the structures at the os uteri.

Suppose, however, that the means we used to avoid compression of the cord, by placing it in the least occupied point at the brim, or by preventing the soft parts pressing upon it by the fingers, or otherwise, were in vain, and that at last it really became irretrievably compressed, and its pulsations arrested before the head could possibly be extracted, is the safety of the child utterly hopeless? I believe not. Long ago, Pugh and Morlanne recommended a practice that has been latterly followed by Bigelow and others, and which, I believe, is calculated in some instances to enable us to continue the life of the child, by continuing its respiratory function, whilst we go on exerting, from time to time, those cautious yet decided means, which we have seen Dr. Denman recommending, for effecting the complete extraction of the obstructed head. The means to which I allude consist in exciting pulmonary respiration in the half-born child, now that its placental respiration is stopped, and in making it continue that vital process by the action of the lungs, now that it is prevented by being exercised, by the medium of the placenta and umbilical cord. "When the parts are well made," says Pugh,* "and the child in proportion, happy the case! It will come then any way; the arms being brought down, the head only remains to be extracted, which must be done with as much expedition as possible, as indeed the arms ought to be; for, consider, when the child has passed the navel, the circulation between it and the mother is stopped from the pressure of the umbilical rope; you must then introduce the fingers of your left hand into the vagina, under the child's breast, and put the first and second fingers into the child's mouth pretty far; so far, however, that you are able to press down the child's tongue in such a manner, that by keeping your hand hollow, and pressing it upon the mother's rectum, the air may have access to the larynx; you will soon perceive the thorax expand, as the air gets into the lungs. *By this method* (he adds,) *of giving the child air, I have saved great numbers of children's lives, which otherwise must have died.*"

Acting on the plan thus suggested by Pugh, we may in some cases be able, with a little management, to change thus the respiration of the infant from its intra-uterine to its extra-uterine type, though the head were still held and arrested at the brim; for the mouth of the infant is always then within reach, and could, I believe, be used for the purpose of admitting a proper quantity of air into the pulmonary passages, even when the great bulk of the head is still held above the brim. It is a practice, at all events, which sometimes succeeds sufficiently well when the head is down in the pelvis, and we have all the difficulties of a rigid outlet and perineum to contend against, in our attempts either to extract the head, or to admit a sufficiently free access of air to the mouth of the fœtus. The two following cases which I extract from Dr. Lee's "Clinical Midwifery," will illustrate and impress the practice and the remarks upon it, which I have just made:—

Case XXXII.—The nates presented, the trunk and extremities were extracted, "but the head could not be drawn through the external parts, from the rigid state of the perinæum, and the pulsations of the cord were becoming more and more feeble. So great was the resistance of the perinæum, that it was impossible to overcome it without destroying the child. I pressed back its edge, however, so far, that the external air could enter the mouth of the child, and it respired in this way fully twenty minutes after the pulsations of cord had ceased. In spite of all our care, the edge of the perinæum gave way as the bulky part of the head passed through the external parts, but the child sustained no injury, and continued to live."†

Case XXXIII.—I attended a lady in her first labour, on the 22nd October, 1837. The nates

* "Treatise on Midwifery," 1754, p. 49.
† "Clinical Midwifery," Case 239, p. 129.

presented, and the cord ceased to pulsate after the trunk and extremities of the child had been extracted. The perinæum was so rigid, that the head could not have been delivered without using so much force, that the parts must have been torn, and the neck of the child injured. I held the body of the child as far forward as possible, while Dr. H. Davies assisted me in holding back the perinæum, that the air might enter the mouth of the child. The respiration went on for nearly half an hour before the head could be safely drawn into the world, and during the whole of the time there was no pulsation in the cord. The child is alive, and the perinæum was not injured."*

The child may not only be able to breathe, but even heard to cry, with the head still unborn, when this form of treatment is adopted. In his paper on the subject, published in the *American Journal of Medical Sciences*, for 1829, Professor Bigelow states, among others, the following case:—

Case XXXIV.—In a case (No. 3, p. 288,) of arm-presentation, in which the feet were brought down, and the body delivered, "the face turned towards the perinæum, the mouth was easily reached, and the fingers were opened to give passage to the air as before described. No struggle nor attempt at respiration however occurred. A handful of cold water was then dashed upon the body, upon which the child immediately gave a spring, and began to cry. The head was not delivered till some minutes afterwards."

In his observations and directions upon this modification of practice, Dr. Bigelow observes:—"After the body is expelled (p. 285,) if the head can be seasonably delivered, either by the recurrence of pains, or by the successful efforts of the practitioner, no difficulty ordinarily occurs. But this desirable state of things cannot always be realized; too frequently the size of the head, and the resistance of the pelvis or soft parts, renders the delivery difficult or hazardous, and the practitioner, in the midst of his efforts, is apprised by a convulsive jerk, or spring of the body, that a state of extreme danger exists, and that the time has come at which the child must breathe, or will speedily die. If at this period the fingers be introduced, so as to reach the mouth of the child, it will be perceived that each jerk of the body is attended with a gasp, and convulsive effort at inspiration, performed by the mouth and chest of the child. In this state of things, if air be conveyed to the mouth of the child, it will immediately breathe, and the efforts of nature, as will hereafter be shown, may, in most cases, be safely waited for to assist in expelling the head."

"The method to be pursued," he continues, "in conveying air to the mouth, depends upon the situation of the head. If the chin has descended low in the pelvis, so that the mouth rests upon the perinæum, or lower part of the sacrum, and can be readily reached by the fingers, the hand of the operator alone is sufficient to give the assistance required. But if the mouth is situated so high in the pelvis as to be reached with difficulty, or if, from the large relative size of the head, there is much compression, the assistance of a tube may be of use. The mode of proceeding which I have found successful in various instances, is as follows:—As soon as the body and arms are extracted, supposing the face towards the sacrum, an assistant supports the body, carrying it towards the pubes; or the reverse should the position of the face be to the pubis. The accoucheur should then introduce the hand to which the face looks, till the middle fingers rest upon the mouth of the child; the hand is then to be raised from the throat of the child, making the ends of the fingers a fulcrum, and pushing the perinæum backwards; the air will thus pass upwards as far as the chin of the child; the middle fingers are now to be separated about half an inch from each other, and thus a complete passage will be formed between them, by which the air will reach the mouth of the child. If the child be in a healthy state up to this period, it will immediately breathe and cry, and the delivery of the head may be safely postponed till the natural pains recur. If, from any degree of asphyxia, the child does not immediately breathe, it may often be made to do so by dashing cold water upon the body, or by other stimulating processes. It has even appeared to me practicable to inflate the lungs in some cases, through an elastic catheter. When the mouth is so high in the pelvis as to be reached with difficulty, or when the compression is so great as to obliterate the cavity between the fingers, a flat tube will be found useful, made of metal of spiral wire covered with leather, or of elastic gum, and having its largest diameter about half an inch. If the tube be of metal or of any incompressible material, it should be withdrawn during a pain, to prevent contusion of the soft parts, and immediately replaced, if the pain subsides without expelling the head. Such a tube may be considered as a prolongation of the trachea, and is fully sufficient to sustain life by respiration for a considerable time. The tube must be guarded and directed by keeping it between the fingers of the inserted hand."

In addition to the above remarks on the possible means of preventing fatal compression of the umbilical cord, there is one observation more which I am anxious to make. If all the preceding measures fail to avert compression, there is always still one strong hope left, namely, that if after complete compression of the umbilical vessels has occurred, no very great length of time is lost in the extraction of the head, the child may yet be born alive. For the type of vitality in the unborn infant is such that it will often survive, and be capable of being resuscitated, although the placental respiration be arrested for several minutes before its actual birth. And with others, I have been repeatedly surprised, in such cases as we are considering, both at

* "Clinical Midwifery," Case 241, p. 131.

the great amount of extractive force which the structures of the infant will sometimes undergo without life being destroyed, and at the apparent great length of time, during which, in making these extractive exertions, the infant will still survive, and that too, although the cord was compressed during their continuance. If the infant be perfectly viable, and its heart sounding normally at the time that turning is adopted, there are perhaps comparatively few cases in which it will be requisite to expend so much time upon the forcible compression and extraction of the head as to destroy during that time the child's life by simple compression of the cord alone. The following case (which occurred within the last few days,) may perhaps impress this remark. In it the fœtal heart continued to beat regularly, not only after the cord was compressed for a considerable time, during which very strong exertions were made in order to extract a large and very firm head through a pelvis three inches in its antero-posterior diameter, but its pulsations went on for several minutes, even after the head was perforated, an operation that required some time for its performance, and after the cervical spine had yielded under the traction applied.

Case XXXV. Along with Drs. Ziegler and Weir, I delivered, at the Maternity Hospital, on April 17th, a woman, aged 19, in labour with her first child. The os uteri was fully dilated, and the child's head had remained at the brim during nearly ten hours of active labour-pains. The parietal bones were riding over one another at the sagittal suture, and the right parietal bone was somewhat indented by the sacrum, upon which it rested. The conjugate diameter measured about three inches. A very deep dose of chloroform was given. Turning was effected, and the body of the child delivered. Strong traction was applied in vain to bring the head through the contracted brim, and at last the bones of the neck offered to give way. The cranium was then perforated behind the ear, and by the aid of a crotchet in the mouth the delivery was completed. The child did not breathe, but the pulsations of its heart went on regularly for several minutes after delivery. The child weighed upwards of seven pounds. It measured twenty-one inches in length. Its head was large, and firmly ossified.

Concluding remarks regarding the objections to the proposed practice founded on the alleged danger and death of the child.

In terminating the present section of our subject, I would again repeat in regard to the whole, the argument which I have used against the alleged fatality of the individual sources of danger that we have inquired into. It has been averred that under the proposed practice of turning in distorted and contracted pelves the injury which the fœtal head must sustain would be fatal to the child,—the injury of the neck would be fatal to it,—the injury of the cord would be fatal to it. I have shewn the principal fallacies to which these arguments are individually liable. Against the truth of the whole in a combined form, I would here again simply and strongly appeal to the evidence of facts and experience. For the results of the cases of the practice that I have given and of others that I may yet have occasion to give, amply attest that in various instances in which it has been adopted, the indentation and depression of the skull of the infant were not fatal to it, nor was the traction of the neck fatal to it, nor the pressure upon its funis. It was submitted to one and all of these sources of supposed danger and death, and yet escaped alive from all. And having done so when the principles and details of the practice were not at all understood, may we not expect still happier and more successful results when these principles and details come to be better comprehended and more systematically acted upon?

I have heard turning objected to by some in arrestment of the head at the brim, on the ground of its inevitably occasional, or rather frequent, fatality to the child. But when we have any new operation proposed, with the view of replacing other operations, such as turning in distorted pelvis, instead of delivery by the long forceps or craniotomy, we can only properly judge of the real and relative value of the new operation, not by looking at its own absolute and isolated results, but by looking at its results as compared with the results of those other operative measures for which it is suggested as an alternative. Now, as regards the respective value of turning to the infant in comparison with the two operations for which I propose it as a substitute, the case is, of course, very different, according as we contrast it, *first*, with the long forceps; or, *secondly*, with craniotomy.

We have seen that the fatality to the child from the common operation of turning in transverse and cephalic presentations, was, in the Dublin and Parisian hospitals, nearly the same as the common operation with the short forceps, or indeed was in favour of turning, in neither set of cases there having been any very special state of pelvic contraction; and perhaps, if we had any adequate data, we should find that the same analogy in their results held good when they were respectively applied under greater and increased degrees of difficulty as in morbid contractions of the pelvic brim, always, however, with this important difference in favour of turning,—that it could be employed at a much earlier, and, consequently, as respects both the mother and child, at a much safer period of the labour than was fitted for the adoption of delivery by the long forceps; and always, also recollecting that the comparison of the results of turning, with the results of short-forceps operations, is imperfect in this respect,—that from the *direction* of the compression in long-forceps operations,—viz., in the antero-posterior or oblique diameter of the fœtal head, the danger and mortality to the child is generally far greater than when the short instruments merely are used, the direction of the compression with them being transverse.

But, delivery by the long forceps, under any conditions, is an operation entirely rejected by many eminent accoucheurs, and very seldom indeed adopted in country practice. And I have already often stated, but cannot, perhaps, too often repeat, that it is principally as a substitute and alternative for craniotomy in contracted states of the pelvic brim, that I bring forward the operation of turning. Now, as far as regards the child, the results of these two modes of delivery—craniotomy and turning, in this special and not unfrequent set of cases, is easy of comparison and settlement. For the very essence of the one operation, (craniotomy,) is the actual death and instrumental destruction and mutilation of the child. The object of the other operation, (turning,) is to offer the child, under the very same circumstances, a chance of escape and of life. Craniotomy implies the inevitable sacrifice of the infant. Turning implies its possible safety and probable survival. And the distinction between them which has latterly been always uppermost in my own mind, is this:—delivery by craniotomy consists in opening and breaking down the skull so as thus to reduce it to such dimensions as will allow it to pass through the contracted pelvic brim; but the operation which I propose to substitute for it, and by which the requisite diminution of the fœtal head may likewise be produced, consists, not in fatal opening and emptying of the skull, but in compressing, and, if necessary, depressing its flexible and elastic parietes; and further, I have shewn that extraction by turning affords us the means of effecting this compression and indentation without always compromising the life of the infant. As far then as regards the safety and life of the infant, I hold that any general comparison between craniotomy and turning is altogether and entirely in favour of the new practice. But how stands the comparison between the effects of the two operations in relation to the safety and life of the mother? To answer this question a separate section is required.

(*To be continued.*)

CASE OF SPASM OF THE LARYNGEAL MUSCLES.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

I should not have thought the accompanying case worthy of being offered to you for publication, as it appeared to me so obviously explicable on the principles of modern physiology, if it were not that it bears directly upon a point which I see, with some surprise, has been made a subject of controversy between two gentlemen who have lately written in the Journal, Dr. Ogier Ward, and Dr. Wardell.

It occurred, as appears by the date, more than two years ago. The subject of it was a young lady, aged about 28, of a delicate constitution, and much deformed, a teacher in a school. I transcribe it from my case-book, as it was hurriedly written down at the time, with only some slight verbal corrections; as I have no wish to take any share in the controversy, I send the simple facts, without comment. It is to be supposed that the object of both the gentlemen referred to is, rather to elucidate truth, than to maintain a theory, or gain a victory; and that any example which may contribute to that end, and to the clearer understanding of an important point of pathology and practice, will be acceptable to either party, and to your readers generally. I trust, therefore, that the subjoined simple narrative, in illustration of the disputed question, will neither require apology, nor be considered an intrusion on your pages. I am happy to be able to add, in confirmation of my own views of the case, that of my friend Mr. Forman, who kindly saw the patient with me at my request. We neither of us had the smallest doubt as to the spasmodic and reflex nature of the symptoms. The case is headed in my notes, "Spasms of the Laryngeal Muscles."

February 17th, 1846. Called this morning in haste to Miss M. R., whom I found in the following state:—She was sitting in a chair, supported by attendants, labouring for breath, which she drew at long intervals, with a loud inspiratory crow; at each inspiration the chest heaved strongly. She could speak only with great difficulty, and pointed to the throat, where she said she felt a constriction. The face was pale and dusky; the hands cold; the pulse feeble, *not* quick; no palpitation of the heart; complained of *intense pain in the head.* The spasmodic action varied in intensity; at times the heaving effort of the chest in inspiration was much more prolonged than at others, and this was at times so great, and the intervals between the inspirations so long, that I feared immediate suffocation. Some æther and spirit of lavender being at hand, were given in warm water, and the feet were placed in hot water, with mustard. These means were quickly followed by considerable relief to the spasms. Previously to this, some fluid, apparently wholly mucus, was discharged by spontaneous vomiting. She was now undressed and got into bed, and was breathing with but slight spasmodic action, accompanied still by the crow in inspiration. The urgent symptoms were passed, but they returned from time to time in a less severe degree.

The patient is subject to violent attacks of pain in the head, vomiting, and other symptoms of gastric and hepatic derangement. This state of things appears to be the cause of her present distress, the irritation returning by reflected action to the respiratory muscles. The indications, therefore, are—the most urgent symptoms being removed—to get rid of unhealthy gastric or intestinal secretions or other offending accumulations, and to soothe the general and local nervous excitability.

An antispasmodic draught, containing a sixth of a grain of muriate of morphia, with æther and compound tincture of cardomums, to be given, if the spasms returned strongly, and repeated in half an hour or an hour, as required. As she had taken no food, a little piece of dry toast, and a small cup of coffee, without milk, were allowed, to be followed in an hour by a warm aperient draught of rhubarb and senna.

2, p.m. Is breathing freely and tranquilly; spasms have returned now and then, but not severely, and are immediately relieved by a dose of the medicine.

7, p.m. Better in all respects; spasms have returned two or three times, but not alarmingly; skin moist and warm; pain in the head less violent; bowels not yet moved.

R. Pilul. Hydrargyri, Extracti Hyoscyami, utrq., gr. iij.; Pulv. Jacobi, gr. ij. Fiat pil. hora somni sumenda.

18th. Has had a tolerably good night; a few slight spasms have returned occasionally only; bowels moved twice by the medicine; headache gone; skin cool and natural; pulse 68; no tenderness on moderate pressure along the larynx and trachea, but she feels as if there were a lump in the throat. She says she is very susceptible to impressions of cold air in the throat, and has occasionally had in the night slight attacks of the same character as the present, but they have not been severe enough to occasion any alarm.

I am, Sir, your obedient servant,
EDWARD DERING WALKER.
Extra-Licentiate of the Royal College of Physicians.

Teignmouth, June 30, 1848.

ON DIVISION OF THE FALCIFORM BORDER OF THE FASCIA LATA, FOR VARIX OF THE SAPHENA VEIN.

By William Bird Herapath, M.B., (Lond.) M.R.C.S., Bristol.

Without entering into a discussion of the various causes productive of a varicose state of the veins of the inferior extremities, yet I hope to be able to show that there is one cause which has hitherto escaped the attention of surgical authors, and that it also admits of an easy remedy.

Varix has been too generally thought to depend upon an imperfect condition of the valves of the venous trunks. That this alone is the case in some instances, I will not dispute, but if pressure exist upon the vein at any point intermediate between its radicles and the right side of the heart, distension of the distal portion will be produced to such a degree, that the valves can no longer close the dilated vein; but remove the cause of the enlargement, and the valves again become capable of resuming their functions.

The superficial cutaneous veins are most commonly affected. These are the internal and external saphena, both of which have to pass through apertures in the deep fascia, in order to reach the larger trunks, into which they deliver the circulating current. Now, should these apertures at any time be too small to allow the passage of the quantity of blood carried by the veins, distension must ensue, and varix result.

Long standing in the upright posture creates a *relative decrease* in the size of the aperture, inasmuch as more blood is then sent by the heart to the inferior extremities, and an opening capable of passing the quantity returned in the horizontal position, might become incapable of doing so in the altered circumstances herein spoken of.

The accompanying case proves the position here maintained, and at the same time shows the points of diagnosis upon which to found an opinion, whether the operation of dividing the saphenous border will be effectual or not.

The case detailed was purely a varicose state of the internal saphena, but it is possible that the external saphena might be also varicose in the same subject, and require a distinct operation for its cure; but should the popliteal vein be also varicose, the seat of the obstruction would of course be on or above the external iliac vein, and that remedy must be used which may be applicable to the circumstances of the case.

The operations hitherto adopted for the removal of a varicose state of the saphena relieve by *obliteration* of the vein; consequently advantage is taken of anastomotic communications, and the circulating current is simply directed into other venous trunks. But the plan which I have proposed and tested by experiment is more philosophical, as it restores the circulation in the natural direction, by removing the cause of the obstruction.

It is an operation devoid of danger when carefully performed, and therefore when applicable, it presents additional advantages over those hitherto proposed, as they nearly always give rise to more or less inflammation of the veins, which has not unfrequently been followed by fatal consequences.

Case.

Mr. Atkins, aged 24, consulted me April 19th, 1848, for a varicose state of the veins of the left leg and thigh. Eight years ago, after some excessive exertion, inguinal hernia made its appearance on the same side, for which he wore a truss during four years; this has been left off ever since, as he thought it no longer necessary. The present state of the veins first made its appearance five years ago, and has considerably increased latterly. It gives him great uneasiness, as his occupation obliges him to stand during several hours in the day; the pain is, towards night, almost intolerable, and is of a dull aching character, the veins almost threatening to burst. When in the recumbent posture, all distension disappears, but almost immediately upon assuming the erect position, the veins again acquire their former size.

The internal saphena and its branches alone are varicose. The tributary branches on the inner side of the belly of the gastrocnemius muscle, are very tortuous, and much dilated. A swelling, as large as a walnut, occurs at the inner border of the internal condyle of the femur; the walls of the veins, and the skin over them, are so thin, that there is imminent danger of bursting in this spot; from hence, nearly up to the saphenous opening, the vein presents one regular

tube-like form, much dilated, being nearly as large as the third finger, but at about one inch and a half from this fascial aperture, the vein is dilated nearly to the size of the first phalanx of the thumb. The pudic and iliac branches of the vein are also slightly varicose and enlarged. The branches of the dorsum of the foot, and below the calf, are not much enlarged. The popliteal vein cannot be felt. The external saphena is perfectly healthy. The spermatic veins are also nearly imperceptible.

These diagnostic points led me to conclude that the cause of the obstruction was not higher than the saphenous opening; and I thought that a stricture at this point, acting as a ligature, produced the retrograde dilating power. The pressure of the truss, probably, ad some connection with the origin of this. But, in order to see what effect the thorough evacuation of the colon would have on it, I gave him a brisk cathartic dose of turpentine and castor oil, previously to attempting operative measures. As I had anticipated, no diminution of the swellings occurred, although the medicine acted very powerfully.

Having explained to him the anatomy of the parts, and the supposed cause of obstruction, together with the method of relief proposed to be adopted, he at once fell in with the proposition, and said he was willing to undergo anything, provided there was any chance of benefitting him, as he was heartily sick of the annoyance and inutility of bandaging.

On April the 27th, I proceeded to perform the operation of dividing the falciform border of the fascia lata, assisted by my friend Mr. Edward Martin, who fully concurred with me in adopting the plan, and also by my pupil. The patient was placed in the same position as in the operation for femoral hernia; and as he had requested that æther should be administered to him, Mr. Martin kindly undertook the management of this part of the proceedings. When he had become thoroughly under its influence, I pinched up a fold of skin between my fingers sufficiently large, and then transfixed and divided it with a pointed bistoury; an incision three inches in length was thus obtained obliquely upwards and inwards, immediately over the swollen termination of the saphena vein. The superficial fascia was remarkably thin at this spot, and having carefully dissected it away from its attachment to the falciform border, and then with the pointed bistoury carefully passed *directly upwards* immediately beneath the iliac layer of fascia, (the vein being depressed and protected by my left fore-finger,) I divided the crescentic border of the saphenous opening, to the extent of half an inch, which of course considerably enlarged the aperture, and at once removed the stricture, and the varix immediately disappeared. At this stage of the operation the patient most unexpectedly gave a kick, the point of the bistoury penetrated one of the abdominal branches of the saphena, probably the superficial epigastric, and hæmorrhage to a greater extent occurred than the operation necessarily involved. Pressure with the thumb immediately controlled, and a sponge full of cold water soon stopped it. About two or three ounces of blood were lost.

The wound was closed by two points of suture, and drawn together by adhesive plaster, and the whole covered by a pad of wet lint, held on by a few turns of a bandage. The patient was carefully drawn into bed, and quietness was peremptorily enjoined.

The wound healed kindly almost by the first intention, and without a bad symptom.

May 11th. He was allowed to get up; *no enlargement of the veins* occurred, although no support has been hitherto applied.

14th. He has been out walking for a short time; no sign of the return of the varix appears. There is a hardened clot, the size of half a pea, in the situation of the swollen portion of vein, at the internal condyle; the other portions of the venous trunk are but little larger than in the natural state, so that the operation may be distinctly proved to have been perfectly successful.

Had I not depended too much upon the peculiar quiescent power which æther generally produces upon the muscular system, the little accident which took place would not have occurred, and but little blood would have been lost. In future it will be advisable to use a probe-pointed bistoury at this stage of the operation.

CASE OF TUMOUR IN THE AXILLA, THOUGHT TO BE CACINOMATOUS.

By George Murray Humphry, Esq., F.R.C.S.,
Surgeon to Addenbrooke's Hospital, Cambridge.

Esther Strickland, aged 57, admitted into Addenbrooke's Hospital, Nov. 27th, 1844, a woman of strong frame and not unhealthy appearance, though rather thin. She considers herself to be in indifferent health and suffers much from a sensation of sinking at the pit of the stomach. There is a tumour of stony hardness, about the size and shape of a hen's egg, in the left axilla, lying upon the ribs, projecting a little beneath the edge of the pectoral muscle, and extending up to the clavicle. It raises the pectoral muscle so as to cause slight prominence in front. The natural depressions above and below the outer third of the clavicle are filled up, and even rendered prominent, so that the clavicle occupies a depression between them. There is also rather more resistance, as well as fulness, above the clavicle on the left side than on the right, though no distinct tumour can be there felt. The left external jugular vein is fuller than the right, and a little tortuous. The woman suffers pain of a darting stabbing character, occurring occasionally, and confined to the region of the tumour. The breast is healthy.

She is the mother of a large family, always enjoyed good health till the period of the cessation of the catamenia, three years ago, since which time her health has been indifferent and she has been troubled with sinking at the stomach. For a considerable period, more than a year, she has felt, on first waking in the morning, some numbness, swelling, and stiffness in the fingers of the left hand, which passed off in an hour or two. About two months ago, she had uneasiness in the arm-pit, and then first discovered a lump as large as a sparrow's egg. This lump has gradually increased.

This tumour was judged by myself, and the other surgeons of the hospital, to be of carcinomatous character, but as it extended to the clavicle, if not higher, and was attended with numbness and swelling of the hand, we agreed in not recommending any attempt to remove it by operation. I did not see her again, but was informed that the tumour increased in size, and that she died not many months after leaving the hospital.

MODE OF REDUCING DISLOCATIONS OF THE HUMERUS AT THE BRISTOL INFIRMARY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In an early volume of the "Transactions" of our Association I published a short account of the mode of reducing dislocation of the humerus, which has been practised at the Bristol Infirmary for a great many years. As that method appears not to be generally known, although its principle is recognized in other ways, I have thought a re-publication of it may not be unacceptable to some of your readers. The experience of the present surgeons of the infirmary fully confirms that of their predecessors in finding it a plan so uniformly successful in all recent cases of dislocation, whether into the axilla or otherwise, that I may venture to assure those who will give it a trial, that they will very seldom indeed encounter any of those difficulties in the reduction which seem occasionally to be met with in the adoption of other modes.

Without any preliminary treatment, the patient is seated sideways on a firm chair, with his arm hanging over the back, which is well padded; one end of a double or reel-towel is passed through the other end, so as to form a noose, which is applied to the arm just above the elbow. The loose depending part of the towel forms a stirrup, into which the surgeon places his foot, and gradually brings his whole weight to bear on the towel, as an extending power. One or two assistants are useful to press back the acromion, and keep the patient firmly in his seat. The reduction is effected almost immediately, and if due precaution be observed in properly padding the chair, and the arm where the towel is applied, little or no pain is felt, nor any subsequent inconvenience from the pressure.

I am, Sir, faithfully yours,

W. F. MORGAN, F.R.C.S.,

Surgeon to the Bristol Infirmary.

Bristol, July 19, 1848.

ON THE EFFECTS OF THE ACETATE OF THE OXIDE OF ETHYLE; AND ON AMMONIA, AS AN ANTIDOTE TO ANÆSTHETIC AGENTS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In the year 1847, whilst at College, I was induced to try several of the organic compounds, and amongst the rest, the acetate of the oxide of ethyle. Having made some of this compound, one evening, not being aware it had before been tried, I went down to the hospital, when one of the students gladly consented to inhale it. In three minutes, he was completely under its influence; I pinched him and tried various manœuvres with him, but without any perception or feeling on his part. Satisfied in some measure with the result, and being called to an adjoining apartment, I left him, but I had not been absent above five minutes before I heard a shriek, and immediately returned to see what was the matter. I found it was one of the nurses, who, upon coming into the room, saw the gentleman upon whom I had been experimenting, lying motionless and powerless upon the ground. Not thinking that I had left as much æther on the handkerchief as would harm him, I had left without apprehension; and he, like many others of the present day, having tasted and imbibed what was at first pleasant and exhilirating, had inhaled the compound again. I could feel no pulse, and the pulsations of the heart were all but suspended. Having first dashed some cold water upon his face, and afterwards directed that they should rub his hands and feet with a warm towel and put a warm flannel cloth to the region of the heart, I ran to procure some Aqua Ammoniæ, being almost hopeless of his recovery. He inhaled a portion of the vapour and at first gave a kind of convulsive effort, but in about three minutes, by its neutralizing influence, he quite recovered. He remarked, that he felt it almost as soon as he had taken it, to go directly to his very extremities. He also stated that he had taken or been under the influence of sulphuric æther and chloroform before, after which he had always felt a degree of sickness and uneasiness, but with this agent, (the acetate of the oxide of ethyle,) he did not in the least.

I would observe, I have seen about forty operations with sulphuric æther, and fifty with chloroform. When the patient manifests pain with sulphuric æther, I have remarked it to occur when cutting through the skin, and when with chloroform it is in cutting through the larger trunks of the nerves. I have seen two deaths from chloroform; one man was in convulsions for forty-eight hours after the operation, and afterwards expired. It would appear to exercise a peculiar influence on the sympathetic system of nerves, and on the medulla oblongata, and there would seem to be no real antidote; but the agent I have mentioned, (Aqua Ammoniæ,) and some other of the alkaline compounds, may possibly tend to neutralize and destroy its effects.

I have also tried the acetate of the oxide of ethyle upon various of the inferior animals, but I will only trespass upon your valuable time in relating an experiment upon the cat tribe, in order, as I think, to confirm and strengthen what I have before stated, as to the neutralizing properties of the volatile alkali.

I gave it to a cat, and produced anaæsthesia; in about three minutes it was completely insensible to my perception, and under soporific influence; it then took one or two inspirations of Aqua Ammoniæ, when it sprung from my knees with one enormous leap.

I immersed another animal in this agent, and it seemed completely dead to my appearance, and then immersed it in Aqua Ammoniæ, and next morning it moved its limbs, and seemed lively.

A cat sustained a dislocation; it seemed to labour under very excruciating pain, and severe shock. I gave it the agent I have named, the shock was completely subdued, and it was astonishing how it recovered.

I am at present making experiments with another compound, which I have never seen nor heard tell of being tried, and which I think has considerable claims as an anæsthetic agent.

Allow me, Sir, in conclusion, to relate one other experiment which I have performed since I wrote the above. I took a frog's foot, and immersed it in the acetate of the oxide of ethyle; in about three minutes and a half it was perfectly paralysed, and by a continuance of the immersion, the other leg participated in the effect; the frog could not stir in the least. I then took and immersed it for a moment or two in Aqua Ammoniæ, and immediately the frog could jump about, and seemed to have completely lost the anæsthetic state.

I remain, Sir,
Your obedient servant,
R. OASTLER JOHNSTON.

Willow Cottage, Bramley, near Leeds,
June 27, 1848.

PROVINCIAL
Medical & Surgical Journal.

WEDNESDAY, JULY 26, 1848.

The determination of the minimum dose of any poisonous substance capable, independently of idiosyncracy, of producing fatal effects, is of so much importance in reference to medical jurisprudence, that we are induced to make a few observations on the case of arsenical poisoning, recently published in this Journal. (See p. 347.) The case, as related by Dr. Castle, of Leeds, gives, as far as we know, the smallest dose of arsenic hitherto recorded as having proved fatal. In Mr. Taylor's excellent work "On Poisons in relation to Medical Jurisprudence and Medicine," the latest and best authority on the subject of which it treats, a case is referred to in which "*two grains and a half* of arsenic, contained in two ounces of Fly-water, killed a robust healthy girl, aged 19, in thirty-six hours." The case was reported to the Pathological Society of London, by Dr. Letheby, and was published in the *Medical Gazette*, for January 15, 1847. "This," says Mr. Taylor, "I believe to be the smallest fatal dose on record; and it will justify a medical witness, in stating, that, under circumstances favourable to its operation, the fatal dose of this poison is from *two to three grains*." Dr. Castle's case, in which the quantity taken was still smaller than in Dr. Letheby's, (half an ounce of Fowler's solution, containing not more than two grains of arsenious acid,) comes strongly in favour of Mr. Taylor's inference, and gives additional value to the opinions on this subject expressed in the work referred to and elsewhere. Our valued correspondent, Mr. Hunt, in commenting on this case, in the last number of the Journal, (p. 391,) seems to have misunderstood Dr. Christison, when he brings him forward as authority, (by inference,) for six grains, (for an adult,) being the smallest fatal dose of arsenious acid. Dr. Christison, it is true, states this as the smallest fatal dose that had come within his knowledge, but he does not say that less than this quantity may not prove fatal. A reply by Dr. Castle to Mr. Hunt's observations will be found in another column, which renders it unnecessary for us to extend these remarks further in this place, as the remaining features of the case are therein commented on. In the *Medical Gazette*, (July 14, p. 87,) where the case is quoted from the *Provincial Journal*, we find the following remarks appended by the Editor:—

"This case is interesting, from the fact that, admitting arsenic to have been the sole cause of death, it is the only instance recorded in which Fowler's mineral solution has destroyed life. The whole quantity of arsenic taken by the deceased in a period of about five days amounted to 1.83 grains. This is the smallest dose of arsenious acid which has yet been known to have proved fatal to an adult. The poison, probably from its having been given in small and divided doses, did not produce the usual symptoms of vomiting and purging, although its irritant action on the alimentary canal was indicated by intense inflammation. It appears in this instance to have destroyed life by indirectly affecting the heart, and by inducing fatal syncope. It may be a question, however, whether some other irritant substances were not simultaneously administered for the purpose of inducing abortion."

We may observe that, though the suggestion here made might possibly in part explain the intense inflammatory appearances observed in the mucous lining of the stomach and intestines, the fact still remains of the unequivocal detection of the arsenic in the tissues of the stomach and in the liver.

Review.

Susrutas. Ayurvèdas. Id est Medicinae Systema a venerabili D'Hanvantare demonstratum a Susruta Discipulo compositum. Nunc primum ex Sanskrita in Latinum Sermonem vertit, Introductionem, Annotationes et Rerum Indicem adjecit Dr. FRANCISCUS HESSLER. Tom. ii. *Erlangae apud Ferdinandum Enke.* 1847. Large 8vo. pp. 250.

Two years ago (1846. April 8, p. 160,) we gave a short notice of the first volume of this work, and it was, perhaps, in this Journal that the attention of the medical profession in this country was first directed to it. We did not, indeed, pretend to give anything like an analysis of its contents, but merely recommended it to the notice of the medical public, in the hope that some of our more profound and learned contemporaries might be induced to examine it more fully than we had leisure and space to do. Our expectations were not disappointed, and shortly afterwards the subject of ancient Indian medicine was again brought before the public, in Dr. Royle's learned and interesting article on Susruta, and on Dr. Wise's "Hindu System of Medicine," in the *British and Foreign Medical Review* for April, 1847.

To this work we refer our readers for further information on the subject, while we must once more content ourselves with the humbler office of announcing to the medical profession in this country the appearance of the second volume of Dr. Hessler's Latin Translation of Susruta.

The whole work consists of six books, or divisions, of which the first volume contained the first two, entitled "Principiorum Medicorum Doctrina," and "Pathologia." The present volume contains the next three,—viz., "Somatologia," (or Anatomy,) "Therapia," and "Antidotorum Doctrina." The next volume is to contain the last portion of the work, which (as we find from Dr. Wise's "Hindu System of Medicine," p. 9,) treats of various local diseases, the different kinds of fevers, consumption, diseases of the heart, &c. This third volume will also contain the translator's introduction, notes, and indices, which we shall expect with some degree of eagerness, as it must be confessed that at present great part of the work is totally unintelligible to us.

After making this confession, it would manifestly be presumptuous if we were to venture to pronounce any decided opinion, either on the execution of the work, or on its medical value.

The third volume will shew whether the translator has bestowed on his author all the care and attention required for such an undertaking; and with respect to the other point we can only say, that, though the work contains several things that are probably not to be found in any ancient Greek, Latin, or Arabic medical treatise, we cannot help doubting whether upon the whole the Hindus were superior to these nations in medical science and skill; while our European tastes are so formed on the model of Greece and Rome, that we are inclined to think that most of our readers would find their medical writings more repulsive than even Paulus Ægineta, which at its first appearance met with such unfair treatment at the hands of some of the members of the Sydenham Society. Still we have no hesitation in saying that Dr. Hessler's Susruta is a book that quite deserves to be found in every public medical library, and the more so as we fear the price of the book is such as to prevent its finding a place in many private ones.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

Continuation of Mr. Crompton's Digest of the Depositions on Burns and Scalds, made at Inquests held before James Chapman, Esq., Coroner for the Borough of Manchester.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death	Parts which were burnt.	How the accident occurred.	Remarks.
			1841				
161	M.	5 yrs.	June 12	2 days	Arms, breast, belly & thighs	Night gown caught fire standing on the fender. Alone. Mother out.	Infirmary (out-patient.)
162	M.	37 yrs.	July 31	6 hrs. (about)	All over his body except chest & back. Lungs and air passages were also scalded	Bursting of a steam-pipe, in connection with a boiler.	Infirmary. Verdict—"Internal scald, from inhaling hot steam." &c. &c.
163	M.	2½ yrs.	Aug. 9	5 days	Right foot and knee, hips, shoulders, and bottom	Fell into a mug containing some hot water	Dispensary. (Linseed oil and lime-water.)
164	M.	3 yrs.	Aug. 25	22 hrs.	Arms, legs, belly and back	Severe scalds from falling off a gate into a sluice of boiling water, running from a steam engine	——

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the Accident occurred.	Remarks.
165	M.	42 yrs.	Sept. 2	3 days	Breast, thighs, back and arms	A druggist. Making composition for congreve matches. It exploded and set his clothes on fire	——
166	F.	3½ yrs.	Sept. 25	2 days	Not stated	Not known how. Father at work; child without mother. Woman in charge had gone into the next house	Infirmary, (out-patient.)
167	F.	5 yrs.	Sept. 27	6 days	Right side, belly, neck, and arms	Left alone by her sister, aged 11, who had been left in charge. Neighbour heard her scream, ran into their cellar, and found her in flames. No mother	Infirmary.
168	M.	4¼ yrs.	Oct. 17	12 hrs.	Severely scalded upon breast, arms and neck, and one of his feet	He fell and upset the coffee kettle which was upon the fender	Infirmary, (out-patient)
169	F.	4¼ yrs.	Oct. 18	12 hrs.	All over except feet and a little of back	Parents out	Infirmary, (out-patient.)
170	F.	2 yrs.	Oct. 20	21 hrs.	All over her body	Parents out. Pinafore took fire	Infirmary, (out-patient.)
171	F.	2½ yrs.	Oct. 20	2 days	Head, left shoulder and arm	Kettle fell off the fire	Convulsions.
172	F.	13 yrs	Nov. 15	2 days	All over except feet	Fell asleep while reading with a candle upon her knee.	Infirmary.
173	M.	4 yrs.	Nov. 18	11 hrs.	All over except back	Not known how. Mother making beds	Treacle and flour applied immediately.
174	F.	4 yrs.	Nov. 16	3 days	Back, and right cheek and legs	Scalded by kettle falling off the fire	Infirmary, (out-patient.)
175	F.	10 yrs.	Nov. 20	17 hrs.	All over	Frock caught in lifting off the kettle	——
176	F.	8½ yrs.	Nov. 23	2 days	Breast, right arm, shoulder and face	In putting coals on the fire, her handkerchief caught. Parents out	Infirmary.
177	F.	5½ yrs.	Nov. 27	3 hrs.	All over her body	Pinafore caught. Mother at the door of the house. The child *(for fear of being beaten)* did not scream or give any alarm, but ran up stairs under a bed, to which she set fire. The smell of fire and the smoke issuing from the window led to the discovery	——
178	F.	6 yrs.	Nov. 28	2 days	Face, head, throat, right thigh, arms, and hands	A burning bit of rag, thrown into the fire by her sister, fell out upon her clothes	——
179	M.	2 yrs.	Dec. 4	9 days?	Right arm and cheek, breast, & right thigh	Child playing on the hearth, when the coffee kettle tilted on one side	Linseed oil and lime-water
180	F.	66 yrs.	Dec. 11	16 hrs.	All over, except belly	Gown caught fire when her back was towards the fire. Not sober	Infirmary.
181	F.	3¾ yrs.	Dec. 24	13 hrs.	Arms, breast, & face	Left in charge of a girl aged 11 years, who allowed her to be alone	Infirmary.
182	F.	61 yrs.	Dec. 24	4 days	Arms, breast & face, and right side	Drunk. Set her clothes on fire when lighting a candle. Alone.	Infirmary.
183	M.	21 yrs.	Dec. 30	Immediate death.	——	Suffocated and scalded by steam being suddenly directed upon him from a boiler	——
184	F.	6 yrs.	1842 Jan. 4	15 hrs.	All over, except feet and part of legs	Standing on the fender chalking the chimney-piece. A girl of 8 years in charge. Parents out	Infirmary.

No.	Sex.	Age.	Date of Burn.	Interval between burn and death.	Parts which were burnt.	How the accident occurred.	Remarks.
185	F.	5 yrs.	Jan. 6	4½ hrs.	All over, except back	A cripple. Left with two young children, one of whom it is supposed set her on fire. Mother in the yard	Infirmary.
186	M.	2¾ yrs.	Jan. 4	20 hrs.	Knees, stomach, arms and face	Lighting chips. Mother out	——
187	F.	8 yrs.	Jan. 8	20 hrs.	All over, except feet	Alone. Not known how	Infirmary.
188	M.	3 yrs.	Jan. 7	23 hrs.	Bottom of his belly and right side of his head, & right arm	Clothes caught in reaching something off the top of the oven. Mother out	Dispensary.
189	F.	1⅔ yr.	Jan. 8	21 hrs.	Back and waist, legs and feet	Scalded by the mother tilting a panful of water over upon the child upon the hearth	——
190	F.	11 yrs.	Jan. 10	22 hrs.	All over, except feet	No mother. Father bed-fast. The van at the door to take him to the Workhouse. Child supposed to have been taking a potato out of a pan on the fire	Infirmary.
191	F.	11mos.	Jan. 10	14 hrs.	Neck,arms,head, ears and back	Mother out. Left with two children, eldest of them 5 years' old. One of them threw a lighted stick upon her	Infirmary, (out patient.)
192	F.	1⅔ yr.	Jan. 10	48 hrs.	Thighs, belly, arms and chin	Left by parents, along with a twin (sister,) on the hearth, there being no fender. A cinder supposed to have fallen upon her. Parents out	Infirmary, (out-patient.)
193	M.	37 yrs.	Jan. 13	8 hrs.	All over his body except his face	Fell into a brew-pan containing boiling beer. Not sober	Infirmary.
194	F.	6¾ yrs.	Jan. 13	19 hrs.	All over except left arm and head	Clothes caught in stirring the fire. No one older in the house	Linseed oil and lime-water
195	M.	5¾ yrs.	Jan. 16	11 hrs.	All over	Left locked up with another child. Man passing by saw flames in the cellar, burst open the door. The other child and the bed were on fire	Infirmary.
196	F.	6 yrs.	Jan. 8	7 days	Arms, breast and face	Reaching coffee off the chimney-piece	Infirmary.
197	M.	1⅔ yrs.	Jan. 7	9 days	Face and neck	Pulled a jugful of boiling water off a table upon himself	——
198	F.	28 yrs.	Jan. 9	12 days	All over, except legs and bottom of back	Apron caught fire while reaching to the chimney-piece. Instead of lying down she ran from room to room	Infirmary.
199	F.	5¾ yrs.	Jan. 24	17 hrs.	All over	Rubbing the bar with her frock	Infirmary, (out-patient.)

Proceedings of Societies.

BATH AND BRISTOL BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

The Seventh Annual Meeting of the Bath and Bristol Branch Association was held in the Lecture Room of the Bath Literary and Philosophical Institution, on Thursday, June 22nd.

There were present Drs. Blackmore, Daniell, Davies, Goodridge, M'Dermott, James Watson, Messrs. John Barrett, Bartrum, Barrow, Cox, Church, Evans, George, Hanks, Hunt, King, Mason, Norman, Ormond, Skeate, Stone, Skinner, G. Skinner, of Bath; Drs. Bompas, Simmons, Messrs. Burrow, Colthurst, Estlin, Hetling, Lancaster, Morgan, Ogilvie, Swayne, of Bristol; Dr. Morgan, of Bradford; Messrs. Farnham Flower, of Chilcompton, Race Godfrey, of Yatton; Washbourne, of Corsham, &c., &c.

In the absence of Mr. N. Smith, the President of the Branch, Mr. Ormond, took the chair, which, after congratulating the members on the continued success of the Branch Association, he gave up to Farnham Flower, Esq., the President for the ensuing year, who read the following address:—

Gentlemen,—I cannot better commence the short address with which I am about to trouble you, than by thanking you cordially for the very honourable position in which you have placed me upon the present occasion. I thank you, not only on my own behalf,

but also on behalf of that department of the profession which I, though so humbly and imperfectly represent, I mean the rural practitioner. It must, I think, strike every one who has been accustomed to watch steadily those changes which are insensibly affecting society at large, and our professsion in particular, that a very great alteration has occurred, as to the estimation in which general practitioners are held both by the public and by the profession itself. This change is obviously attributable to the great improvement which has been effected in medical education, and which happily is still progressive; much need of it is there still, not only that those who undertake our onerous and painfully responsible duties should avail themselves of all the benefits to be derived from the immense accessions which every year is making in the medical and surgical sciences, but also that they should be able to meet and in some measure satisfy the requirements of the non-professional public. Time was, and I am old enough to remember it, when that which patients even now have in their mouths whatever they may feel in their hearts, I mean implicit confidence in their medical attendant, was very common, that state of mind being one of mere faith and non-enquiry. Thus Mr. A or B had been the medical adviser of the patient's father or mother, or his own adviser for twenty years and more; he (that patient,) had never troubled himself about physic, he was quite sure Mr. A or B, who had cured so many of his family could also cure him. Such was then the state of mind, confidence not in actually ascertained knowledge of the attendant, but simply in individual respectability of character. There were no fashionable systems of cure then afloat, perturbing the public mind; there were quackeries it is true, empirics wandering through the country, vaunting their cures in particular diseases; neither were there in those days, books upon "Physiology made easy," and "Every man his own Doctor," which now suggest all sorts of enquiries to our patients and their families,—inquiries absurd enough and difficult to deal with from the mixture of sense and nonsense. But still such questions must be answered. Moreover, there were no express trains in those days; it was not easy when there seemed any unwillingness or inability on the part of the medical practitioner to impart information upon cases, or to adopt a plan of treatment in accordance with the preconceptions of the patient or his family,—it was not so easy to start off to the metropolis, or even to the nearest provincial city, in pursuit of further advice. All this is now changed: the laity are wide awake, or at least they think so, and we rural practitioners are compelled to bestir ourselves; and I hope we are doing so not unsuccessfully. Certainly one of our great helps is in the formation of such Associations, as that, over which, through your kind, but I fear undeserved consideration, I have now the honour of presiding,—Associations which at due intervals draw the country doctor out of his fastnesses into the society of his brethren in adjoining cities, enabling him if he has not had time by reading and study to keep pace with the current literature of his profession, to have in conversation, as well as formal meetings, the newest results of scientific investigation and the products of individual experience. From these meetings, he goes back with his wits on the alert, alive to many things which before he had never dreamed of in his philosophy, and hopeful of reciprocating from his own observations some of the additions to his knowledge obtained from the experience of others. I trust also, that from these meetings, where he has opportunity of coming into contact with minds and characters of the highest order, he may return with an increased sense of the dignity and honourableness of the art which he professes. For in these meetings he learns not only to meet the views of the public, but in some measure to lead them, and to rely not on *ad captandum* methods, but on those which have their sure foundation in the truth of things, and which it is fully as much to the interests of the public as of the profession, that we should command and enforce. From my own professional acquaintance, which is not a small one, I am satisfied that a very marked change for the better is going on in professional bearing.

My friend, Dr. Symonds, in a letter which he addressed sometime since to Dr. Forbes, in the *British and Foreign Medical Review*, and in which he at once defended the orthodox plans of treatment, and exposed the follies of some of the popular systems, as well as the more dangerous doctrine, which was creeping into the profession, (I mean excessive reliance on the curative powers of nature,) remarks,—"I am of opinion that it is not so much a reformation or revolution in medicine that is wanted, as a more thorough and extensive education of practitioners in the art and science of medicine, as it at present stands. The most intelligent and accomplished must sigh for knowledge in a thousand directions, but the interests of medicine very loudly demand that its professors should know what is already known."

With these sentiments I fully accord, and confess that I have more hopes from this sort of reform than from mere changes in the political condition of the profession, though these are not without their value, and I congratulate my brethren on the changes which are taking place.

These alterations, whatever other good effects they may accomplish, will, at all events, confirm the properly educated medical man in his position, and the public will have the opportunity of judging, if they choose to avail themselves of it, as to who are, and who are not, by training and experience, qualified to take upon themselves the care of the sick and suffering.

I am anxious to occupy as little of your time as possible on the present occasion, but I feel that I ought to make use of the position in which I am now placed, to express my hope that my professional brethren will constantly keep before their eyes the moral obligation under which they lie. We are not engaged in mere pursuit of money or fame, we undertake the charge of that on which hang the dearest interests, not only of our immediate neighbours, acquaintances, and friends, but even of untold generations; for who can tell how much hangs on the life of a man—nay, of the most immature infant; and not

only on the life, but also on the health. As an illustration, we may, by a careless mode of procedure, not actually involve the life of the patient, yet deprive him of that which makes life desirable; we may so break down the tone of the nervous system, that life has ever afterwards lost its sweetness, and the individual who was the sole support and encouragement of his family, may become a source of continual anxiety, vexation, and irritation; his mind may be full of causeless suspicions and jealousies, or, what is scarcely less painful to contemplate, of habitual gloom and unfounded apprehensions. Such results may ensue from the best medical treatment, for which, with safety to life, there was no alternative, but we must feel convinced that in pursuing it we have chosen the right course. There is no satisfaction for us, in our many anxieties and perplexities, but in conscientiously determining to allow no considerations of ease or comfort, convenience, or popular opinions, to divert us from prosecuting what, to the best of our knowledge, judgment, and experience, is the right thing to be done. In this is included the duty of taking the best means in our power of improving our own knowledge; when we once acquire this habit and singleness of purpose, our course is plain and easy; we do our best, and leave the issue to an all-wise and all-benevolent Providence. If we endeavour to work on that high and christian feeling which should characterize the actions of all, and none more than medical men, we shall find our task will be less burthensome, and our reward will be sure, if not in a worldly point of view, at all events in comfort and peace of mind,—a reward beyond money and beyond price.

Mr. Bartrum, the Secretary for Bath, then read the report of the Council for the past year, which was unanimously adopted by the meeting.

Report.

The Council of the Bath and Bristol Branch of the Provincial Medicial and Surgical Association, in presenting this, their seventh Report, cannot but congratulate its members on the interest taken in the proceedings of the Association, and especially on the continued success of the quarterly meetings, the full attendance at which shows that they are valued as affording pleasing opportunities of professional intercourse, and cementing those friendly feelings that should exist among the members of a liberal profession.

It is also gratifying that the numbers included in the Branch Association have steadily increased, though occasional fluctuations must be expected.

The proceedings of the past year present but little requiring a detailed report or particular notice.

The subject of Medical Reform has so often been brought before your notice, as now almost to lose its interest; nevertheless, a subject so important to the interests of the future race of practitioners cannot be wholly passed over, your Council are therefore gratified to learn, that after the many vain attempts to modify the views and balance the interests of the various bodies governing the different branches of the profession, there is some probability that a legislative enactment sanctioned by them, and satisfactory to the bulk of the profession, should at last have been agreed upon, and will probably become law. The proposed measure, though not embracing several of the points strongly urged on the attention of previous Governments by deputations from the Association, appears to offer the only present probability of the settlement of this long and much agitated question. The part of the measure appearing to press unjustly upon the future English general practitioner is that, requiring of him to pass two examinations in surgery before two Boards with conflicting interests. Notwithstanding this, it is gratifying to learn, that the examinations and qualifications of the various Boards of the kingdom are, as far as possible, to be assimilated.

In the correspondence connected with the proposed bill, it will be scarcely necessary to remind the members of the Association of what marked benefit to physicians of a certain standing has been the intervention of the general Council. It should, however, be always remembered, that no legislative enactments will avail to consolidate the interests of the profession, or make it more respected by the community at large, unless its members, in their individual capacity, feel that to each other they owe a duty as strong as to themselves, and that while endeavouring to augment the usefulness of their divinely sanctioned art, they should not be harsh to the failures or failings of their neighbours.

Your Council are also pleased to observe, that the just claims of those ill-requited members of our profession entrusted with the care of the parochial poor, are being enforced on the attention of the government, who cannot fail to perceive the hardship commonly entailed on those obliged to undertake such duties, and they feel convinced that it is only necessary for the public to have their attention drawn forcibly to the matter by their professional brethren, in order, ere long, to place the medical relief of the poor on a footing more favourable to the sick, and more equitable to their medical attendants.

The hopes not only of the public but of the profession, having so often been raised, that the Legislature would enact a Sanitary Bill, remedying some of the causes of disease and death, it is with much pleasure that your Council can congratulate the Association in the prospect of some provision (however inadequate,) being made against the endemic sources of disease so abundant in our densly crowded cities. They, nevertheless, feel it incumbent on them to state their belief, that the sanguine expectation entertained by many engaged in this good cause of removing so large an amount of sickness, misery, and death, by mere sanitary improvements, is contrary to that sound judgment founded on experience, which it should be the aim of members of our profession assiduously to cultivate.

During the past year, by the untiring zeal of Mr. Newnham, the recently appointed secretary of the Benevolent Fund, the claims of this fund have been brought before the notice of each member of the Association; his appeals have been responded to by some of our members, but not to the degree commensurate with his endeavours, or with the paramount importance of the object in view, as many members still refrain from extending by this channel the help so often needed by the disabled practitioner, or his widow, or his children.

Though not forming an integral part of the Association, your Council hail with pleasure the formation within both cities of two Societies devoted to Pathological research, and having kindred objects with our quarterly meetings. Instead of regarding these with jealousy, all must rejoice to see this or any other indication of professional zeal, since the aim of all must be the same who desire to raise the character of the profession by making observation more accurate, and deduction more correct, thereby adding to the efficiency of the healing art, and thus conferring a lasting benefit on mankind.

After alluding to the loss of Dr. Riley, and noticing him as a man of the most intense industry and high philosophical mind, devoted to anatomy in its highest branches, the Council expressed their sincere hope that each member of the Association will use his earnest endeavours to make each meeting more instructive and more agreeable, and thus do his part to render permanent and more useful the Bath and Bristol Branch of the Provincial Medical and Surgical Association.

It was then resolved on the motion of Mr. Morgan and Mr. R. Godfrey, that John C. Swayne, Esq., of Clifton, be the President-elect.

The Secretaries and Council were re-appointed, with thanks for their services during the past year, William Church, Esq, being elected to fill the vacancy in the local Council, caused by the retirement of Peter Marriott, Esq.

The following resolutions were then proposed, and after some conversation thereon, unanimously adopted :—

Resolved—

"That the number of the local Council in future do not exceed 36, the like proportion being selected from the cities of Bath, Bristol, and the rural districts."

"That any member of the local Council, who, during one year shall not be present at one meeting, (illness or absence from home excepted) shall thereby be rendered ineligible for re-election during the year next ensuing."

The thanks of the meeting having been voted to the Committee of the Literary Institution for the use of their room, and to the President for his able conduct in the chair.

RESPONSIBILITY OF THE INSANE.

Dr. Daniell read a "Case of Poisoning by Prussic Acid, with observations on the relation of such cases to moral Insanity and Medico-legal Medicine." This case will be published in the Journal.

Mr. Hetling drew the attention of the members to the varying strength of prussic acid at the druggists' shops, Mr. Godfrey having found it in Bristol to vary 70 per cent. subsequent to the interesting case narrated by him, and published in the Journal of 1844, p. 398.

Mr. John Barrett begged that this meeting would not sanction the present fashionable doctrine, that decided moral insanity could or did exist without some intellectual insanity.

Mr. Ogilvie observed, that after a long experience he found, that though insanity might affect chiefly, or almost wholly, the moral faculties, yet to those intimately acquainted with persons labouring under this malady, some degree of intellectual aberration was always present, and that in such cases the bodily functions were ill-performed, and very constantly bodily ailment preceded the attack of insanity.

Mr. Estlin, though opposed to the punishment by death, had viewed some of the recent verdicts in cases of this character with great fear, as the tendency to such verdicts had been wholly to exculpate those, who, in pursuance of their designs, had shown full powers of reasoning, whose crimes had been marked by cool premeditation, and by a long-continued neglect of that control of the passions and feelings that was essential to the comfort of the individual, and the safety of the community.

Dr. Blackmore confirmed the remark of Mr. Ogilvie, that in all cases of moral insanity, the bodily functions will be found more or less failing.

Dr. Davies read the history of a "Case of Rheumatic Paralysis, treated by Electro-magnetism, with Observations thereon." The case will be published in the Journal.

MALIGNANT ERYSIPELAS AFTER PARTURITION.

Mr. G. King then narrated two cases of "Malignant Erysipelas after Parturition" which had occurred in his practice :—

On February 4th, he had attended Mrs. T——, in her third labour; her room was airy, house well situated; the labour was natural, and soon over. At the time she had a swollen face, which was hard, and much inflamed; it had disturbed her rest for some nights previously. She went on very well for two or three days, when the inflammation now became erysipelatous, extended around the neck and over the chest, with great constitutional disturbance, delirium, diarrhœa, &c. The submaxillary swelling went on to suppuration, degenerating into sloughing phagedenic ulcers, exposing the muscles of the neck, and involving a large portion of the upper part of the chest, and nearly the whole of the left breast. Here it was arrested; some parts filled up and healed, and she recovered so far as to be able to be removed to another part of the town. Six weeks afterwards she had an inflammation of the lungs, when she was under the care of another practitioner, and died.

The next case was Mrs. N——, in labour with her first child. February 21st. The labour, though lingering, was otherwise natural. About five minutes after the removal of the placenta there was frightful hæmorrhage, which for some time endangered her life. Except suffering from extreme debility, she went on very well for the first week, when she complained of excessive pains of her legs, which, previous to her confinement had been very large. On examination they presented nothing remarkable beyond their size, Mr. King considering that the pains were due to the reaction. They were well bathed with warm water, and a moist bandage was applied; she, however, became restless and

feverish, and diarrhœa came on. The next day Mr. King's attention was drawn to a small dark bladder beneath the right leg, to which the nurse had applied a poultice. On removing the poultice there was immediately recognized the peculiar fœtor and gangrenous appearance presented by the last patient. The poultice was continued, and the part became clean and healthy, but the diarrhœa continued unrestrained, and she died on March 16th, three weeks after her confinement.

In both cases the diarrhœa was the most unmanageable symptom. Mr. King had delivered eleven women in the interval between the first and second case, none of whom suffered from any untoward symptoms. This latter he had been obliged to visit in the clothes worn after seeing the first case, while in all the others he had been able to avoid that source of contamination.

SOUTH-EASTERN BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

On Wednesday, the 28th of June, 1848, the fourth Anniversary Meeting of this Branch of the Provincial Medical and Surgical Association was held at the Sussex Hotel, Tunbridge Wells, when the following gentlemen were present:—

Messrs. Hargraves, of Tunbridge Wells; Stedman, of Guildford; Martin, of Reigate; Drs. Mackness, of Hastings; Plomley, of Maidstone; King, and Davies, of Brighton; Messrs. Underwood, of Battle; Trustram, Gream, Turner, Rix, Mitchell, and Cook, of Tunbridge Wells; Reid, of Canterbury; Giraud, of Faversham; John Cordy Burrows, of Brighton; Constantine Holman, of Hurstpierpoint; Dr. Butler Lane, of Ewell; Messrs. Stilwell, of Epsom; Newington, of Gondhurst; Samuel Battley, of London; Starling, of Hadlow; Thompson, of Westerham; Pickance, of Penshurst; Bottomley, of Croydon; Gold, of Wateringbury; Long, of Barham, Canterbury; Whitfield, and Wilks, of Ashford; Colebrook, of Southborough; Penkivil, of Staplehurst; Harris, of Northiam; Drs. Soulby, of Dover; Duncan, of Tunbridge Wells; and Silvester, of Clapham.

At one o'clock Mr. Hargraves, the President for the year, took the chair, and addressed the gentlemen present, to the following effect:—

Gentlemen, in taking this chair, and commencing the duties of the office which your kind partiality has assigned to me, and which I wish were in abler hands, my first agreeable duty is to bid you all heartily welcome to this place, which is on this occasion, honoured by the presence of an assemblage from all parts of the district, of gentlemen distinguished for cultivated talent and professional eminence. It is not my design to trespass long on your time and attention in any address from this chair, which would prove only an irksome delay of the far more interesting matter which will presently be submitted to your consideration. The principal objects of this Association are, the advancement of medical science, and the maintenance of the honour and respectability of the profession. This Association affords, therefore, an active and inspiriting stimulus to members to exert their best faculties, and most earnest efforts to investigate professional truths and practical results, so as to arrive at as accurate conclusions as can possibly be attained. To the talents and zeal of the members of our body, the records of our Association bear ample testimony, more especially in the Journal, which has of late been greatly improved: and the sentiments to which I am giving utterance, so far as my judgment and feelings are capable of guiding me, I have no doubt will be responded to by every impartial mind; and each returning year will afford fresh demonstration of the advantages which will result from an Association which has in view the promotion of harmony and good feeling among its members, and the collection and diffusion of facts which may serve to render medical science more signally beneficial to mankind.

The minutes of the last annual meeting at Reigate were then confirmed, as were those of the special general meeting at the same place on the 1st March.

The President then called on the Secretary to read the report of the Committee.

REPORT.

The Committee of the South-Eastern Branch of the Provincial Medical and Surgical Association, as on previous occasions, take the liberty of addressing themselves to their friends and neighbours, members of the Branch, on two or three points of especial, as well as of general, interest; and more particularly as respects the public affairs of the profession, the unsettled state of which has long given great concern to those who have ardently wished for that cordial and harmonious state of feeling, and of sentiment, among all classes of the profession, so much to be desired, and, as your Committee believe, so surely to be attained, by honourably-minded men taking up the consideration of the subject in a liberal and patriotic spirit.

A settlement of the question of Medical Reform, the Committee beg to inform their brother members, is now likely to take place; and certain "principles" have been agreed upon by delegates, consisting of some of the most eminent members of the different medical colleges and corporations of England, Scotland and Ireland, acting on behalf of themselves and their constituents. The "principles" alluded to were unanimously adopted by the Conference Committee; and it may be taken for granted, that every member of the Association has had an opportunity of reading and considering them, as they have been printed in all the medical journals. Some may be of opinion that the plan suggested will prove highly beneficial to the interests of the profession, while others probably may think that an alteration in the constitution of either the College of Physicians, or the College of Surgeons, or of both, without the addition of a third institution, would have better met with the requirements of the age. But the fact of the new arrangements having met with the unanimous approbation of the representatives of the different colleges and corporations who assembled

at the conferences, it is to be hoped, is a guarantee that they will meet the requirements of our body.

With regard to the constitution of the new College of General Practitioners, respecting which much anxiety has been felt and expressed, it is hoped that both the Bill and the Charter of Incorporation, when they are completed, will be found worthy of the approbation of every general practitioner in the kingdom.

Your Committee beg further to express their hope that if this long desired measure of Medical Reform should be accomplished in a comprehensive and liberal spirit, it will eminently conduce to the advantage of every branch of the profession, and likewise to the public welfare, by assuring to the whole population of the country the benefits of a continually improving agency in the treatment of disease; and by inducing the universal prevalence of a friendly feeling, and a good understanding among all sections of the profession, the practice of which has so long been alloyed and embittered by the contention of classes, and the constant intrusion of unqualified pretenders.

This pleasing prospect your Committee contemplate with the highest satisfaction. The calm, delightful, and peaceful pursuits in the study of the science of the profession, and its beneficent practical exercise in the cause ofhumanity, will constitute the great reward on which we shall congratulate ourselves, and each other, when, as we hope, at no distant day, these agreeable anticipations will be realized.

In consequence of the publicity given to the circumstances attending the Croydon inquest, and the consequent resolutions of the Board of Guardians reflecting on the conduct of Mr. Bottomley and Dr. Berncastle, a requisition for a special meeting of this Branch, to take into consideration the circumstances of the case, signed by the requisite number of members, having been sent to the Secretary, he summoned a special general meeting of the members of the Branch, which took place at Reigate on the 1st of March, when certain resolutions were agreed to in vindication of Messrs. Bottomley and Berncastle, which were inserted as advertisements in two daily London papers, two local weekly papers, in the weekly medical journals, and in the fortnightly journal of the Association. They have likewise, as of course, been recorded in the minute book of the proceedings of this Branch of the Association, and have doubtless been read by every gentleman present. It is worthy of particular remark that the medical officers of the Dartford Union, being unable to attend this meeting, most liberally forwarded a special contribution in aid of its objects.

During the past year a vigorous effort has been made to effect an improvement in the system of poor-law medical relief. A meeting was held in London last autumn, at which the grievances which oppress Poor-law Medical Officers, were fully stated, and a Committee was appointed to lay their case before the Government. This Committee has endeavoured to interest the three medical corporations in the matter, and has succeeded in so doing. It has also had interviews with the President of the Poor-law Board, Mr. Buller, and with the Secretary of State for the Home Department, and has obtained from Mr. Buller an assurance that he would consider the whole subject of Poor-law medical relief, with a view to its improvement. The Committee of the Poor-law Medical Convention has also prepared a plan for an improved system, which it is believed would be satisfactory to the profession; but your Committee cannot but feel, so great is the prejudice and the ignorance pervading all classes of the community, even the highest, upon the subject, that great exertions are still necessary to accomplish this most desirable improvement. This fact, however, should not lead to apathy on the part of the profession, but should stimulate to increased exertion, and your Committee are confident that, were the profession generally to exert their influence strenuously and continuously, success would be the result. That which is necessary is, to impress on the minds of rate-payers and guardians the fact, that their interests would be better served by an improved system, and more liberal payment for medical relief.

The Committee of the Poor-law Medical Convention have just issued a short address* on the subject, which your Committee recommend to your attention; and they strongly advise that all the members of the Branch should take every opportunity of impressing upon members of Parliament, guardians, and rate-payers, the impolicy, as well as the injustice, of the present system. No fact can more strongly show the great want experienced by the profession of a better organization than our powerlessness in remedying this great evil. Had the great body of the profession a central organization which really represented its wants and wishes, it would be impossible for a system so fraught with injury to the public, as well as injustice to the profession, to be continued. The Poor-law Medical Officers have experienced the sympathy and the co-operation of all the governing bodies, but neither of the colleges is prepared to take the leading part which should belong to the representatives of the medical profession, and which would be decisive as to the result. It remains, then for gentlemen, whether Poor-law Medical Officers or not, as individuals, to use their best exertions in persuading their friends and neighbours of the iniquity of the present system, and to aid the Poor-law Medical Convention in its endeavours to press the subject on the attention of Parliament and the Government.

At the annual meeting of the parent Association last year at Derby, a Committee was appointed to revise the laws of the Association, particularly as respects the caution to be observed in the proposition of candidates, and the admission of members; likewise as to the most eligible mode of treating the moral or professional misconduct of members, should any cases of gross delinquency unfortunately occur. That Committee will have to present a report at the meeting shortly to be held at Bath, respecting which it will be premature to make any observation, further than that members will do well to continue to be cautious in the recommendation of candidates for membership.

With respect to the Benevolent Fund of our society,

* See *Provincial Journal* for July 12th, p. 389.

our worthy associate, Dr. William Conolly, the treasurer, having, at the Derby meeting, expressed a wish to resign the management of it, on account of the infirm state of his health, and Mr. Newnham, of Farnham, having signified his willingness to be considered as Dr. William Conolly's successor, Mr. Newnham's offer was gladly accepted, and he was appointed the treasurer accordingly. It is well known to every member of the society that Mr. Newnham has always, and upon every occasion, advocated the cause of the Benevolent Fund with the greatest spirit, vigour, and eloquence, at the annual meetings, and by his pen in the pages of the Journal. Since Mr. Newnham's appointment he has been indefatigable in pleading the cause of the indigent widow and orphan, and of the worn-out practitioner himself; and no doubt he has been successful in a corresponding degree in the augmentation of the fund.

Since our last meeting we have had to lament the loss, by death, of our worthy associate Mr. West, who, at the preliminary meeting of this Branch, kindly took the chair. He was also the President of the first regularly-constituted meeting of this South-Eastern Branch, on both which occasions he officiated very much to the satisfaction of the members who were present; and at the time of his decease was a Vice-president. Born at Oundle, the son of a clergyman, he was apprenticed to his uncle, Mr. Lomax, in London. At the conclusion of his professional education he acted as an assistant at High Wycombe, where he distinguished himself by several surgical operations, particularly on the eye. In 1824 he settled at Tunbridge, where he speedily attained eminence, and acquired the confidence of a large circle of friends, by whom he was considered to be a sound and skilful practitioner, availing himself of the various improvements in modern medical and surgical science as they became known. He had a nice and particular, and generally, an accurate diagnosis and discrimination of disease, of its pathological bearings, and of the effects likely to be produced by remedial agents, and prescribed with much boldness, decision, and success. Added to these strictly professional and practical qualifications, he had a very respectable knowledge of geological and botanical science. In a social point of view, Mr. West was much esteemed as an eminently friendly, worthy man, possessing many virtues and excellent qualites, and his loss is much regretted by all who had the enjoyment of his friendship or personal acquaintance.

The report having been read, it was resolved unanimously that it should be adopted and printed.

It was then moved and seconded, and unanimously adopted, "That it appears to this meeting, that Brighton would be a convenient place for the general meeting in 1849; therefore, that the members of this branch of the Provincial Medical and Surgical Association shall be invited to assemble at Brighton on that occasion; and that Dr. Hall, of Brighton, be requested to accept the office of President of this Branch at the Brighton meeting, and for the ensuing year.

"That Dr. Jenks and Mr. Furner, of Brighton, be requested to accept the offices of Vice-presidents at and after the Brighton meeting.

"That Mr. Martin, of Reigate be requested to continue in the offices of Secretary and Treasurer for another year.

"That Drs. King and Plummer, of Brighton; Messrs. Winter and Cordy Burrows, of Brighton; Messrs. G. Weeks, and Henry M. Holman, of Hurstpierpoint; Peter John Martin, of Pulborough; Harris, of Worthing; Thompson, of Westerham; Trustram, of Tunbridge Wells; Peter Martin, of Reigate, and Charles Leeson Prince, of Uckfield; do form the next Committee of management.

"That the best thanks of this meeting are due to the officers and other members of the committee of management for the past year, for the services which they have rendered to this Branch Association at and since the last meeting to the present time; and that they be requested to accept the grateful acknowledgements of the members now present."

In reference to that part of the report of the committee which relates to the subject of Poor-Law Medical Relief, it was moved, seconded, and unanimously resolved,—

"That the profession generally is deeply interested in the improvement of the system of Poor-law Medical Relief; and that the Council of the Provincial Association be urgently requested to continue its exertions for the attainment of an object so necessary to the honour, as well as for the interests of the profession."

In reference to the biographical notice of the late Mr. West, the Secretary was requested to express in appropriate terms to the widow of the late Mr. West, the sentiments of respect for the memory of their deceased brother member, entertained by all the gentlemen present at this meeting, and of sympathy for her loss.

The Treasurer's account was then read and passed.

Medical Clubs.

Mr. Thompson having brought the subject of medical clubs before the meeting, so far as respects persons much above the rank and means of the mechanic, or farm-labourer, availing themselves of their privilege of membership in common with men of very inferior position, for whom such clubs were originally intended, and Mr. Trustram having still further elucidated and confirmed Mr. Thompson's statements, by corresponding facts and observations, it was moved, seconded, and resolved unanimously,—

"That while this meeting approves of medical clubs as a means of adding to the independent character of the lower classes, it is strongly of opinion that such clubs should be strictly limited to the lower classes only.

"That the admission of master tradesmen and persons of independent property into such clubs, is a gross imposition upon the profession, and tends greatly to lessen its usefulness and respectability.

"That the members present at this meeting pledge themselves to discountenance medical clubs, unless this latter class of persons are altogether excluded; or

that a scale of insurance is adopted with regard to them, more commensurate with their means of payment, and their position in society.

"That a Sub-committee, consisting of Messrs. Thompson, Trustram, and Pickance, be appointed, with full powers, to carry out the foregoing resolution in respect of Medical Clubs, and that they have power to add to their number."

(To be continued.)

NORWICH PATHOLOGICAL SOCIETY.

The first meeting of this Society was held on the 15th of last month, in the Museum Room, at the Norfolk and Norwich Hospital, when between thirty and forty of the medical gentlemen residing in that city, and in the adjoining counties of Norfolk and Suffolk, assembled together. J. G. Crosse, Esq., was called to the chair, and in a brief address alluded to the now general existence and formation of similar societies, in most of the important provincial towns of the kingdom, to the interest connected with the study of pathology, and the advantages to be derived from the investigation of so important a branch of medical science. Various rules for the order and management of the Society were then agreed upon by the members, and the following gentlemen were chosen to fill the post of officers to the Society for the ensuing year:—

J. G. Crosse, Esq., F.R.S., Norwich, President.
W. H. Crowfoot, Esq., Beccles, Vice-President.
W. H. Ranking, M.D., Norwich, Treasurer.
J. W. Crosse, Esq., Norwich, Hon. Sec.

The following specimens were then brought before the notice of the Society:—

DISEASED KIDNEY.

Mr. W. E. Crowfoot, exhibited a specimen of granular degeneration of the kidney, and gave the details of the case.

MORBUS CÆRULEUS.

Mr. C. B. Rose, of Swaffham, exhibited a heart which had been taken from a child, eleven weeks old, in which the aorta proceeded from the right ventricle, and the pulmonary artery from the left. The foramen ovale was patulous; the ductus arteriosus pervious; the right ventricle thicker than the left; valves healthy. Hence very little arterial change could take place, though the child lingered for eleven weeks. It was a fine child when born, but wasted rapidly till it died.

CALCULUS OF THE KIDNEY, WITH MALIGNANT DISEASE OF THAT ORGAN, AND OF THE LIVER.

Mr. Rose, of Yarmouth, related the following case referring to the specimen brought before the Society. A man, aged 55, had been the subject some time of a most acute, sharp, cutting pain in his left flank, occuring in spasmodic paroxysms, and never leaving him free from pain. He was attacked in a similar manner twenty-three years ago, and it then lasted three or four weeks, attended with almost complete retention of urine, considerable dysuria, and passing frequent small quantities only, which he compared to dirty gutter water. At the end of this time all his painful symptoms subsided upon the passage in the first instance, of a semi-solid gummy matter, the size of a bean, which dropped away exactly like semi-fluid lime. Immediately following this matter came away two hard dark calculi, exactly similar to pepper corns, accompanied with a plentiful flow of the same dirty looking urine.

Present Condition.—There is no tumour or swelling perceptible in the left flank, although a superficial hardness is very evident between the crista ilii and the ribs above, over which the slightest pressure produces agonizing pain; the skin also appears to be morbidly sensitive over the upper and outer side of the ilium. He can only lie upon his back. The acts of defæcation and micturition have no influence upon his pains. Bowels much constipated. His urine is of a dingy dirty colour, with a pretty copious sediment of small shreds (undoubtedly blood,) and exceedingly albuminous; pulse 75; tongue furred and dry. In the months succeeding this last attack he was at times free from pains, but they never entirely left him, and after awhile became worse. Within the last month of his illness he had symptoms of liver disease, with a sallow complexion, and urine loaded with bile, and he died convulsed.

Autopsy thirty-six hours after death. Upon laying open the abdominal parietes, the small intestines, omentum, and some large distended coils of the larger bowels, were healthy and natural in appearance, but upon handling them there was found to be quite a solid mass, fixed, without form or shape, filling the left side, and encroaching over the vertebræ upon the right side; it was most massive up in the left hypochondrium. The left kidney was sought for, but it was found next to an impossibility to get at it, and afterwards it was obliged to be cut out. The malignant mass which was found in the left side of the abdomen surrounded the left kidney, so as entirely to conceal it; but by cutting and violent tearing, it was at length detached from the ribs and lumbar vertebræ, breaking away gritty and solid. Occupying the kidney was found a large calculus, of coarse, grey, sandy concretion, confined to the cavity of the pelvis and its infundibula, which it had distended, condensing and thinning the walls of it. The structures of the kidney were all converted into malignant masses of yellow fibrinous structure; the same was the case with the mesenteric glands, and left lobe of the liver, which formed the upper and inner portions of this mass, as well as a considerable part of the front of it, the descending colon for several inches being covered by the edge. Upon examining the bowel, numerous round knobs as large as peas and beans projected into it, consisting of the same malignant matter, yellow, and hard. No maligant disease nor contraction of bowel was found in any other part of the alimentary canal. The liver was full of malignant matter, hard, fibrous, yellow, and cheesy-looking, with round lumps thickly studding its whole structure. The spleen was small, shrivelled, and quite healthy; the right kidney was half as large again as natural, pale and flabby, but apparently healthy; the bladder was empty, small, and contracted. The ureter of the diseased kidney could not be distinguished running within the malignant mass. The aorta and its branches were small and healthy.

DRY GANGRENE IN THE LOWER EXTREMITY, OCCURRING IN A GIRL TEN YEARS OF AGE.

Mr. James Cooper, of Filby, near Yarmouth, related the symptoms of this case, which occurred in a girl ten years of age. The girl was of a generally healthy habit, spare, of nervous temperament, and had been subject at intervals to attacks of nausea and vomiting, with palpitation of the heart. On the 10th of April last, (having had one of these attacks the day previous,) she was seized with pain and swelling in one finger; on the 13th with numbness of the legs and hips, especially the left. After a while these left her, but the pain subsequently returned most severe in the right foot, which became cool and livid from the foot to the knee, slightly swelled, of diminished temperature, with some pain on pressure. Leeches, &c., were applied.

On the 17th, the leg was much the same. She had an attack of vomiting this day. The sensation of the limb subsequently became more and more impaired, and the limb more livid. Afterwards there commenced all the symptoms of dry gangrene of the limb, extending as high anteriorly as the middle of the tibia; and posteriorly above the ankle the line of demarcation formed, and vesication appeared.

June 9th. She had no appetite, hectic, considerable discharge from the limb, and no pulsation could be detected in the femoral or popliteal arteries. It was, consequently, deemed necessary to amputate the limb, which was done, and the patient subsequently recovered.

Mr. J. G. Johnson, in trying to account for the occurrence of the disease in so young a subject, thought it must, in the beginning, have been a disease in the arteries—that it was the result of arteritis. And he related some cases that had occurred under his observation, where, in treating the case with this view, upon antiphlogistic principles, he had been successful in allaying the symptoms.

[This girl, and a boy of the same age, whose case is reported by Mr. Dayman, of Milbrook, in the *Provincial Journal* for 1846, p. 302, are, probably, the youngest subjects in which spontaneous gangrene has been known to occur. An instance in a subject aged 23, is recorded in the "Monthly Journal," March, 1848.]

FUNGOID TUMOUR, OCCUPYING THE LEFT LATERAL VENTRICLE OF THE BRAIN.

Mr. Thomson stated that this specimen had been removed from a patient who had been subject for some time to epilepsy and consequent paralysis, and who, ultimately, died of apoplexy. A large fungoid growth was found occupying the left lateral ventricle, which was also much distended with fluid. The brain, with the exception of some congestion, was in other respects tolerably healthy.

The specimens which had been exhibited were presented to the Museum of the Hospital, and the Society then adjourned.

Foreign Department.

MEMOIR
ON THE LOCALIZATION OF SKIN DISEASES.*

By M. Baron.

(Translated for the Provincial Medical and Surgical Journal, from the Gazette Médicale, April 1847.)

DISEASES OF THE VASCULAR APPARATUS.

Roseola.—The patches of roseola are due to congestion of the vascular plexus. Whether the congestion is limited to one order of vessels or not, it is not easy to determine.

Rubeola.—This is but an exaggerated condition of the former state.

Scarlatina.—This disease is due to congestion or inflammation of the venous capillary plexus. The desquamation is thus explained:—In health, the epidermis is constantly renewed upon its under surface, while the cells composing its outer surface are expended and thrown off, no interruption of continuity existing; but during the eruption of scarlatina, the secretion of epidermis is suspended, and there is consequently an interruption in the continuity of this matter. The epidermis which was secreted prior to the eruption is not united to that which is formed when secretion re-commences, and the former is therefore dried up and thrown off.

Erythema is due to a high degree of congestion, united to effusion of serum into the cellular tissue.

Erysipelas is a veritable inflammation of the capillary vascular plexuses. Ribes locates the disease in the venous radicles; and the engorgement of the derma and subcutaneous cellular tissue, together with the formation of abscesses, and the occasional presence of pus in the veins, appear to favour such an opinion. Others consider the lymphatics to be the chief seat of the disease. This is, doubtless, the cause of the vesications.

Pemphigus is a chronic inflammation of the superficial lymphatic plexus of the skin.

Nævus Maternus.—Among the various congenital blemishes to which the infant is subject, most are due to alterations in the cutaneous vascular system, sometimes of the veins, at others, of the arterial capillaries.

Erectile Tumours.—These are exaggerated developments of the vessels of the cellular tissue, and of the true skin.

Purpura is due to extravasation of blood, from the minute vessels of the skin.

To recapitulate, we may have the following alterations in the cutaneous vascular plexuses:—

1. Congestion probably of the arterial capillary system.—Roseola.

2. Congestion, or slight inflammation of the same vessels.—Rubeola.

3. Congestion or inflammation of the venous capillaries.—Scarlatina.

4. Congestion, with slight cellular engorgement.—Erythema.

5. Acute inflammation of the capillary plexus,

* Continued from page 329.

occupying either the veins, the arteries, or both conjointly.—Erysipelas.

6. Chronic inflammation of the superficial lymphatic plexus.—Pemphigus

7. Abnormal development of the superficial capillaries.—Nævus.

8. Exaggerated development of the deeper vascular plexuses and subcutaneous cellular tissue.—Erectile tumour.

9. Extravasation in the tissue of the derma.—Purpura.

DISEASES OF THE PAPILLÆ.

1. Congestion of the papillæ, and of the vascular network surrounding them.—Urticaria.

2. Chronic inflammation of isolated papillæ.—Prurigo.

3. Exaltation of sensibility.—Hyperæsthesia.

4. Diminution of sensibility.—Anæsthesia.

5. Abolition of sensibility, with hypertrophy of the papillæ.—Elephantiasis.

DISEASES OF THE SUDORIPAROUS APPARATUS.

Profuse perspiration, miliary sweat, sudamina, miliary fever, are all different degrees of exaggerated action of the sudoriparous glands. It is doubtful whether sudamina are caused by rupture or dilatation of the perspiratory tubes.

[This portion of the memoir ought to have preceded that inserted in the last number, but was overlooked through the confusion in which the French journals have lately been sent.—For the continuation, see p. 387.]

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS.

Of the memoirs recently presented to this Academy, the most interesting are those relating to obstetrics.

CÆSAREAN SECTION.

M. Malle, Surgeon-in-Chief to the army in Africa, reported a case of the Cæsarean operation, which proved successful both to mother and child. The mother was 19 years old, a *primiparous* patient. She recovered perfectly.

DOUBLE MONSTER.

M. Derieu narrated a case in which labour was terminated without artificial aid, although the fœtus was at full term, and had two perfectly developed trunks, united from the neck to the umbilicus, two heads, and eight extremities. This double monster was dead, and putrefaction had commenced. The mother was aged nineteen.

INTRA-UTERINE FRACTURE OF THE CRANIUM.

The third communication was one by M. Blot, of intra-uterine fracture of the cranium. The mother was twenty-seven years old, and during her labour fell down stairs, and fractured her right thigh. Having removed her to bed, it was ascertained that the head was in the vagina, and a sensation of crepitus was distinctly perceived; the fœtal pulsations were inaudible. The labour was terminated by the forceps, and it was found that blood was effused on both sides, between the cranium and pericranium. Fracture of both parietal bones was also discovered. The dura mater and membranes of the brain were uninjured.

Other communications were presented, none of which were of particular interest.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

The memoirs presented during the past month are—

1. A report by M. Fortex, on the growth of a peculiar cryptogamic plant, in the bread served to the garrison at Budah.

2. A memoir on the means of eradicating the marks of tattooing.

3. A memoir on the active principle of Cannabis Indica.

4. A report by M. Rayer on the signs of death, and the means of preventing premature interment.

General Retrospect.

PATHOLOGY & PRACTICAL MEDICINE.

PARALYSIS OF THE TONGUE FROM PASSION.

The following case is related in the "Medicinische Zeitung." A man, aged 59, of delicate constitution, and choleric temperament, while engaged in a dispute, suddenly lost the power of speech, his intellectual faculties, however, remaining. He was unable from this time to move his tongue freely, or to utter any articulate sound. Respiration, the heart's action, the digestive and urinary functions, were normal. No symptoms of congestion of the brain were to be observed. His physician had recourse to electricity, which was continued daily for from five to ten minutes. In the course of five days the faculty of speech was restored.—*Journal of Psychological Medicine*, No. 2.

CHLOROFORM IN CHOREA.

Mr. Harris, of Rotesdale, relates the following instance of the beneficial effects of chloroform in this disease:—The patient was a female in her seventeenth year. The immediate cause which gave rise to her complaint was fright, the system being, doubtless, predisposed to its influence, owing to a chlorotic state of constitution. The ordinary remedies—purgatives, either simply or in combination with one or other of the mineral tonics—constituted the general treatment for the first ten days of his attendance. The symptoms gave, however, no perceptible evidence of any improvement; the involuntary muscular movements of the extremities especially, as well as those of the face, (causing the countenance to be at times hideously distorted,) continued rather to increase than otherwise, which, together with a constant state of watchfulness by night and day, (in spite of opiates,) contributed not a little to her exhaustion and suffering.

The chloroform was used every day for a week, preserving its influence with her on each occasion for about half an hour, when the muscular movements

became almost magically arrested, and a calm sleep was induced. Upon recovering from its influence, the muscles again resumed their state of excitement, although with decided and perceptible mitigation as to the power and severity of action. The nights, which before were watchful, became now, and without the aid of opiates, devoted to sleep and quietude. Believing that these beneficial results might be fairly attributed, if not wholly, at least in part, to the chloroform, Mr. Harris continued its employment for another week, twice daily, extending its influence to an hour each time, and on a few occasions to an hour and a half. It ought to be stated that the medicines were throughout regularly persisted in, and doubtless might have tended considerably to share in effecting the amelioration, which by this time the symptoms of the disease had undergone. The chloroform had been used rather more than a fortnight; the medicines were continued a few days longer, when the patient became perfectly convalescent.—*Lancet*, June 3rd.

CANCRUM ORIS: RECOVERY.

Two cases of recovery from this intractable disease are reported by Dr. Keiller. The first, a child, aged twenty months, became the subject of diarrhœa, with apthous sores on the tongue. The mouth soon got well, but the diarrhœa continued, and the aspect became extremely emaciated and feeble. He improved somewhat under quinine, but his gums became separated from the incisor teeth, and looked black. Muriatic acid was applied freely to the parts, and quinine and port wine were exhibited internally. In two days the sloughing process had extended to the lower lip, which it soon perforated, and then began to invade the left cheek, which it speedily destroyed. The aspect of the case was now such that recovery was neither expected nor wished for, but the tonic treatment was still persisted in. In a few days the gangrenous process stopped, and the sloughs began to separate, exposing the whole of the cavity of the mouth, and leaving the molar bones bare. The granulating process soon filled up the gap, and in a few weeks a large portion of the lower jaw exfoliated, together with two molar teeth. The place of bone is supplied by a hard gum, and the child is now healthy.

In the second case the breath was observed to be fœtid, and on examining the mouth, the upper gum was seen to be detached from the teeth and sloughy. The gangrene reached the cheek, which it completely destroyed, as in the preceding case. The treatment consisted in the application of nitric acid, and quinine and wine internally.—*Monthly Journal*, June.

[These cases must be considered as unusually fortunate. It has occurred to us to meet with five or six cases of the disease in question, but no external application or internal medicine appeared to have the smallest effect in checking the destructive process, and this we believe is the general experience of the profession. As a means of moderating the horrible stench, which is such as almost to prevent the most tender mother from waiting upon the suffering child, we have found a creosote gargle one of the most efficacious.]

NITRATE OF SILVER ENEMATA IN INFANTILE DYSENTERY.

Mr. Garlike (*Medical Times*,) relates some instructive cases of infantile dysenteric diarrhœa, in one of which great advantage was derived from enemata of nitrate of silver. As he states that he is not aware of the same treatment having been recommended by any writer, we refer him to a clinical lecture on the "Diarrhœa of Infants," (*Half-Yearly Abstract*, Vol. iv., p. 199.) In this lecture the following passages occur :—"If colitis accompany diarrhœa, it is necessary to act locally upon the large intestine, and this we do effectually by medicated enemata,—an injection, containing two grains of nitrate of silver to eight ounces of fluid, &c."

DIAGNOSIS BETWEEN SYPHILITIC AND SCROFULOUS AFFECTIONS OF BONE.

This is laid down as follows by Ricord :—

Syphilitic Affections of Bone.	*Scrofulous Affections of Bone.*
1. Very rare with young subjects.	1. Very frequent in youth.
2. Syphilitic antecedents.	2. Scrofulous antecedents.
3. Compact textures of the bone attacked.	3. Spongy tissues of bone attacked.
4. Superficial layers attacked.	4. Deeper layers attacked.
5. Little tendency to hyperostosis.	5. Much tendency to hyperostosis.
6. The pains which precede the development of the affection, increase and become very intense, until they decrease again.	6. The tumefaction precedes the pain, but the latter soon increases, and becomes more intense as the disease proceeds.
7. A tendency to circumscription.	7. A tendency to diffusion.
8. Exostosis.	8. Hyperostosis.
9. Ossification, eburnation, but seldom suppuration.	9. Tendency to softening, suppuration, caries, and necrosis.
10. Rapid cure under appropriate treatment.	10. Difficult cure, and sometimes impossible.

Lancet, June 10.

SURGERY.

WOUND OF THE HEART.

The following case is narrated by Dr. Alexander, of Charlestown, U.S.:—The deceased, whilst engaged in a scuffle, received a blow on his back, which arrested his attention; he turned and pursued the man who struck him, but another man followed him, who, while in the rear, and on the left side of the deceased, was seen to strike him with his left hand, in which was an open knife. The deceased immediately put his hands to his side, and, exclaiming "I am a dead man," staggered a few steps and fell; there was but little external hæmorrhage. He was taken to a neighbouring house, and died 78 hours after the infliction of the wound. On inspecting the body after death, two wounds were found upon the left side of the chest, one below the clavicle and over the second rib, which had arrested the instrument; this wound was seven-eighths of an inch long, but of trivial importance. The other wound was over the fifth rib, three-fourths of an inch from its junction with its cartilage; it was surrounded by a livid circle of considerable extent. Upon examining it with a probe, an indentation of the rib was perceptible, and upon opening the chest, the left

cavity was found filled with bloody serum. There were also signs of acute inflammation of the pleura, and an incision, corresponding to the wound on the surface, was seen on the internal surface of the ribs, by which the rib itself was severed, and the intercostal artery divided. This wound was found also to have entered the throat and pericardium obliquely, and to have passed entirely through the heart, about half an inch from its apex, opening and traversing the left ventricle, and wounding the diaphragm. There were a few ounces of bloody serum in the pericardium.—*American Journal of Medical Science*, January, 1847.

OBSTETRIC MEDICINE.

RUPTURE OF THE UNIMPREGNATED UTERUS.

M. Gozzo, of Naples, narrates the following extraordinary case:—A woman, aged 34, the subject of dysmenorrhœa, and sterile, was examined. The uterus was felt above the pubis, as large as at the fifth month, but perfectly destitute of inequalities of its surface. The uterus continued to increase until its fundus reached the xiphoid cartilage; the menstrual discharge was irregular, and followed by considerable leucorrhœa. She was shortly seized with symptoms of intestinal obstruction, from which she was recovering, when she was suddenly seized with collapse and abdominal pain, and died in less than twenty-four hours.

After death the peritoneal cavity was found to be almost filled with pus, mingled with serous fluid and fœtid gas. The uterus adhered to the lateral parts of the abdomen, from the pubis as high as the umbilicus, filling the iliac regions; it was covered by the large omentum. The intestinal surface was irregular, and covered with fungous excrescences and tubercular masses of various sizes and forms, its cavity being filled with a white inodorous pus. The uterine walls were thickened, and contained several small abscesses, some of which were close to its peritoneal surface. The posterior aspect of the organ exhibited a rent, through which the matter had escaped into the abdomen. An encephaloid tumour was likewise found occupying the lower segment of the uterine surface.—*Archives Générales*, Mars, 1848.

INFLUENCE OF INSUFFICIENT FOOD ON THE GROWTH OF THE FŒTUS.

Dr. Frentruss relates, in *Casper's Wochenschrift*, the case of a woman, thirty six years of age, who was pregnant for the third time. So short were the diameters of the pelvis in consequence of rickets, that he had been obliged, in the two former deliveries, to perforate and extract. He resolved in the present instance not to await the full period of gestation, and was proceeding to provoke premature labour towards the thirty-second week, when he found that the fœtus was so small that its position could in no way be ascertained; nor was he more successful a fortnight afterwards. Dr. Frentruss was then struck with the idea of *starving* the child, to keep it within the dimensions of the pelvis, and very low diet, with occasional purgatives, fully answered his expectations. At the usual time of gestation, he was able, with the forceps, to extract a *living* child, extremely small and meagre!—*Lancet.*

MEDICATED PESSARIES.

The following are those chiefly used by Dr. Simpson:—

Zinc Pessaries.—R. Zinci Oxidi, dr. j.; Ceræ Albæ, dr. j.; Axungiæ, dr. vi. Misce et divide in pessos quatuor.

Lead Pessaries.—R. Plumbi Acet., dr. ss.; Ceræ Albæ, dr. iss.; Axungiæ, dr. vi. Misce.

Mercurial Pessaries.—R. Unguent. Hydrarg. Fort. dr. ij.; Ceræ Flavæ, dr. ij.; Axungiæ, oz. ss. Misce.

Iodide of Lead Pessaries.—R. Plumbi Iodidi, scr. j.; Ceræ Flavæ, scr. v.; Axungiæ, dr. vi. Misce.

Tannin Pessaries.—R. Tanninæ, scr. ij.; Ceræ Albæ, scr. v.; Axungiæ, dr. vi. Misce.

Belladonna Pessaries.—R. Extr. Belladon., scr. ij.; Ceræ Flavæ, dr. iss.; Axungiæ, oz. vi. Misce.

Monthly Journal, June, 1848.

MEDICAL JURISPRUDENCE.

METHOD OF RECOGNISING SPOTS OF BLOOD ON THE CLOTHES.

A new method, proposed by M. Piria, depends on the property that fibrin possesses of attaching itself to the texture of the clothes, and on the action of sulphuric acid on articles made of hemp or linen. The suspected texture is to be plunged into concentrated sulphuric acid, which dissolves out all the vegetable tissue, and leaves the fibrin forming a network, in which may be distinguished the impressions made by the texture on which the blood was fixed.

REAGENT FOR STRYCHNINE.

In 1843 M. Marchand described the remarkable and perfectly characteristic property possessed by strychnine of giving a magnificent blue colour, passing quickly to violet, and lastly to yellow, when triturated with peroxide of lead, and a few drops of concentrated sulphuric acid, containing 1-100th of its weight of nitric acid. Since the period above mentioned several chemists have examined this reaction, and M. Herzog has proposed to omit the nitric acid as useless; another chemist proposes to substitute peroxide of manganese for peroxide of lead, and M. Otto prefers bichromate of potash to these oxides, which, according to him, gives rise to a much finer violet colour, and to a certain extent this is the case.

M. Marchand proposes some objections to these omissions and substitutions, and demonstrates that the reagents which he has proposed are the best suited to the purpose.

First, the nitric acid added in the proportion of 1-100th to the sulphuric acid is not useless, as stated by M. Herzog; for by its influence the series of colours is produced much more readily and sensibly than when it is omitted. M. Marchand states that he was aware that strychnine yielded a fine blue colour by the action of pure sulphuric acid and peroxide of lead only; but that it is almost impossible to perceive the red and yellow colours, which are readily perceptible in the conditions described by him: and the author adds that he never said nor believed, as supposed by M. Herzog, that strychnine, when placed in the circumstances described, might serve as a reagent for nitric acid.

As to the substitution of peroxide of manganese for that of lead, the author has only one objection to make, which is that the salts of manganese sometimes possessing a red colour, there can be no certainty that the series of colours obtained belongs properly to the substance supposed to be strychnine, since one of the reagents employed may itself give rise to one of the colours indicated.

The same is the case with the bichromate of potash recommended by M. Otto. This salt produces by its solution in sulphuric acid a yellow or green colour, and it follows that the series of colours indicated by M. Marchand is diminished by at least one colour, and sometimes by two, the yellow and the red, and consequently the reaction is far from being complete.

The method of employing M. Marchand's process is that of triturating the strychnine with peroxide of lead and concentrated sulphuric acid containing one per cent. of nitric acid; by this process the colours obtained are blue, becoming rapidly violet, then gradually red, and lastly, after some hours, it assumes a delicate yellow colour.—*Journ. de Pharm.*, Avril, 1848.—*Chemical Gazette*, May 1, 1848.

THE PRESENT ASPECT OF MEDICINE.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In asking for a very small portion of the columns of the Journal in rejoinder to Dr. Forbes, I would deprecate, in the first place, any systematic answer to the various links of his reply; and still more, anything like that species of logomachy, which turns upon the possible construction which might be placed upon detached sentences of that reply.

Let me also offer my thanks to Dr. Forbes, for the kind and courteous manner in which he has spoken of my paper,—a manner, however, in which I felt assured he would speak, because from my long knowledge of his character, I was certain that literary differences would, in his estimation, make no inroads upon private friendship. Nevertheless, we are essentially at issue; his paper on "Homœopathy, Allopathy, and Young Physic" was carefully perused by me without its having wrought one new conviction, or effected even the semblance of a conversion in my opinions. They remained as at first, except that they were deepened and strengthened by collision, with what appeared to me to be very serious error; indeed, many of these opinions were publicly stated years before the publication of Dr. Forbes's essay. In their present form, however, they were put together shortly after its appearance, but they were consigned to the dark closet of many other papers, which will, probably, never see the light, until I was stimulated to their publication by the occurrence of some most fearful cases,* produced by an adoption of the principles of the "Natural History of Disease;" and by meeting in consultation with the grievous offsets from this heresy, by which the minds of practitioners had been lulled into fatal security, and several valuable lives had been lost, by the absence of active treatment, where it had been indispensably required, in the vain expectation that nature would do her own work, and effect the cure, if curable. It was under these circumstances that I was induced to publish my remarks on "The Present Aspect of Medicine."

And, now, although Dr. Forbes has quoted from my paper, some detached sentences, which give the semblance of an identity of views with his own; yet it would be easy to show, that these are only those portions of truth, which are mixed up with error, in the natural history of disease, which serve to give it currency and to render its influence so insidious and alarming.

It would occupy my time and yours, Mr. Editor, far too long, and too unprofitably to go into the proofs of this assertion; and I must fall back upon the general issue. This, I will venture to say, will bear me out in the observation, that the doctrines and the practice arising from, or advocated by, the respective papers, will appear, to all persons reading them without prejudice, to be diametrically opposed, and might be shown by the numerous letters of thanks I have received for my remarks in *opposition to "Young Physic;"* and if there were really any thing of similarity in the two essays, it is very remarkable that Dr. Forbes should have been so thoroughly miscomprehended.

I verily believe, that were I to meet my friendly antagonist at the bed-side of a patient, we should readily, and thoroughly, and rationally, agree upon the indications, and their mode of fulfilment; but I am equally persuaded, that the effect upon the minds of the great body of his disciples, will be to paralyse exertion, and to induce a system of waiting, not *for indications, but for results.*

Finally, if I have misrepresented Dr. Forbes in any way, I much regret it; I can only say that I then thought, and still think, (however mistakenly,) that there was sufficient ground for all I said. But admitting that I was mistaken upon these points, I shall still claim for myself and Dr. Forbes, that we are both in pursuit of what we believe to be truth, and that we shall both rejoice if the issue of this discussion shall advance our joint object in promoting rational medication,—if it shall have established the paramount importance of medicine, and the secondary, though confessedly great value, of diet, regimen, and hygienic rules,—and if it shall have induced a greater amount of circumspection in forming rational indications, and of fearless judgment in carrying them out into *active*, though not *heroic*, practice.

To my professional brethren I now leave the decision of right and truth between us; and

I remain, Sir,

Yours faithfully,

W. NEWNHAM.

Farnham, July 14, 1848.

* These, probably, I shall publish, as soon as circumstances permit.

REPLY TO MR. HUNT ON THE MINIMUM FATAL DOSE OF ARSENIC.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I am pleased to see that the report of the case of poisoning by Fowler's solution, which appeared in the Journal of the 28th of June, has attracted the notice of so able and indefatigable an inquirer as Mr. Hunt, the result of whose investigations into the medicinal action of arsenic I await with some impatience. Meanwhile will you allow me, Sir, to encroach for a little on your valuable space, while I attempt to substantiate my view of this particular case, and thus to dissent from the belief that the minimum fatal dose of arsenic, or its compounds, is yet known.

When we consider that a third of all the fatal cases of poisoning result from arsenic alone, it is matter for surprise and regret that this drug can be procured by any one in almost every village. A pharmacien of Paris has been fined for leaving his shop without first locking up his poisons; but in this country, an allusion to rats, and a fewpence, will enable the murderer, or the suicide, to procure an ounce of arsenious acid!

Mr. Hunt, in his remarks on the case of H. T., seems entirely to have overlooked the fact, that arsenic was detected in the contents of the stomach, in the stomach itself, and in the liver; if so, the question is not so much whether arsenic was the cause of death in this case (for it can scarcely be doubted,) as whether the case itself be of value sufficient to enable us to generalize, to a certain extent, and to say,—"It is *highly probable* that two grains of arsenious acid, in the form of arsenite of potass, will prove fatal, in circumstances favouring the action of the poison."

When it is stated that the poor woman, H. T., was ill fed, and lived in a cellar, it is not, I think, difficult to conceive, that twenty or thirty minims of Fowler's solution, repeated at intervals till half-an-ounce had been taken, sufficed to originate disease, which, left to its course, terminated fatally.

I fully agree with Mr. Hunt that isolated cases should not be valued at more than they are worth, and I apply this caution in the cases he has cited. Data founded on the use of arsenic, under the eye of the surgeon, can be but partially applied to toxicology, and then only negatively; and, conversely, cases of poisoning, either accidental or designed, are rarely available as guides in therapeutics. That Fowler's solution has been taken in large doses, and for a long time, with comparative impunity, only proves that some constitutions are much less susceptible of the influence of arsenic than others. But many cases of extreme intolerance might be quoted. "Dr. Burne has reported the case of a young female, who took in divided doses, in three days, one-fifth of a grain of arsenic. Symptoms of inflammation of the stomach, and alarming symptoms of a nervous character, appeared, which rendered a discontinuance of the medicine absolutely necessary."* Hahnemann says that one or two grains of the white oxide may prove fatal in a few days. "The effects of medicinal doses, which seldom exceed a quarter of a grain, without causing irritation of the stomach, must convince every one that the general statement of Hahnemann cannot be very wide of the truth.*

The smallest fatal dose hitherto recorded, shows us what *has* proved fatal, not what *may* do so. Such a case is a beacon to warn, not a chart to guide.

Again, "If the substance with which a poison is combined increases its solubility, it generally increases its activity, and *vice versâ*."† And as potass is a recognized constituent of the blood, it is, perhaps, not fanciful to infer that the power of election which determines its presence in the vessels, also facilitates the absorption of a salt having this alkali for its base.

With regard to *post-mortem* appearances. Their presence alone cannot determine a case to be one of poisoning, any more than their absence can prove the contrary. Illustrations of this axiom are scattered throughout every work on toxicology. Notwithstanding the authority of Mr. Hunt, I still doubt whether it be "exceedingly common" to find, after sudden death, intense inflammation of the stomach, duodenum, and rectum, "where no suspicion of poison exists." That redness of the mucous membrane of the stomach is frequently met with is true, and no medical jurist would trust to this *post-mortem* appearance alone as evidence of poisoning; yet, if mere venous congestion were found to co-exist with arsenic in the tissues, the conclusion that they stood in the relation of cause and effect could scarcely be avoided. The degree of inflammation is not always in proportion to the quantity taken. "It is also the general opinion of toxicologists, that arsenic occasions death more frequently through means of its remote effects, than in consequence of the local inflammation it excites."‡

In the case under consideration, I judged the immediate cause of death to be the action of the poison on the heart, and regarded the inflammation of the alimentary mucous membrane as a link only in the chain of causation,—as a valuable point of departure for suspicion to be afterwards verified or not by analysis.

The importance of acute observation, ever-wakeful caution, and sound, cool, and unbiassed judgment, is never lost sight of by the surgeon who has formed a just estimate of the power of his profession for good, or for evil. Such an one does not wear a glossy creed of the newest fashion, but prefers the gold-headed cane of experience. He neither rushes into the arms of "Young Physic," nor is he carried into the air by fumes from the laboratory of Giessen; but, standing on the time-tried rock of induction, "with the free thought placed in the middle," he calmly surveys the whole.

If it be always necessary to guard against the taking hypothesis, the pet theory, the assumptive system, and the mere *ipse dixit*, it is so, *à fortiori*, in conducting a medico-legal inquiry. Here the surgeon is often beset by the artifice and cunning of the murderer, the maniac, and the slanderer, and the scarcely less formidable

examination of the counsel for the defence. A false step may be fatal, and one of the most frequent is that of quoting an authority as dogmatically as a schoolboy demonstrates a problem in Euclid.

The following extracts, from a letter from the distinguished chemist who performed the analysis, besides their direct bearing on the case of H. T——, serve also to strengthen the general argument derived from it:—

"As to the chemical proof in T——'s case, I may state that I operated on the stomach itself, its contents, and the liver,—on each by Reinsch's method, on some by Marsh's also; and that I obtained, from each of the three, metallic arsenic, and on the re-sublimation, arsenious acid."

"When the medical, moral, and chemical testimony concur in proving, *on the whole*, that death has been produced by poison, I think it most futile to argue the contrary from larger doses having been taken with impunity,—from the absence of this or that symptom, lesion, &c."

"My own pretty extensive experience in toxicology for thirty years, and all my reading, tell me that the history of poisons is a history of anomalies and exceptions."

I am, Sir,

Your obedient servant,

HENRY T. CASTLE.

Leeds, July, 1848.

INFLUENZA.

[We have been requested by Dr. Theophilus Thompson to insert the following questions on the last epidemic influenza. Dr. Thompson will feel obliged for any information on the subject, and the replies may be addressed to him at his residence, 3, Bedford Square, London, or to the Editor of this Journal, Worcester.

1. Was there any epidemic or peculiar state of public health prevailing in your neighbourhood prior to the occurrence of the influenza?

2. What were the usual symptoms, and what the most remarkable of occasional symptoms, attending influenza under your observation?

3. What influence had age, sex, mode of life, temperament, and locality, either in securing exemption from the malady, or in modifying its phenomena?

4. At what time did the disease commence in your district?—when attain its height?—when cease? Were relapses frequent?

5. What was the proportion of fatal cases, and what were the principal *post-mortem* appearances?

6. What medical treatment proved most useful?

7. What temperature, and what plan of diet, were most appropriate?

8. What conclusion did you form as respects opiates and bleeding?

9. Was the liability to the disorder influenced by exposure to the air, or by shelter in public institutions, such as schools, manufactories, barracks?

10. Were members of the same household usually affected together, or in succession, and what other facts did you observe bearing on the question of contagion?

11. What did you observe regarding the direction of its advance, and did it appear first in detached houses, villages, or towns?

12. What are the geological features of your district; and what is its condition as respects drainage?

13. Have you any meteorological records regarding the season of the epidemic, or the period preceding?

14. Did any epizootic diseases prevail about the same time?

15. Have you noticed any change in the public health since the epidemic?

Will you have the kindness to mention any other particulars worthy of record, and also to specify what replies are derived from notes taken at the time, and what others from general impression?

Medical Intelligence.

PROGRESS OF CHOLERA.

It is with regret we have to record the fatal progress of the cholera in the Russian dominions. Six large hospitals exclusively intended for cholera patients have been opened at St. Petersburgh. At St. Petersburgh, from June 24th to July 3rd, there were 5,063 cases, of which 2,596 have proved fatal; 198 have been cured; and 2,269 remained under treatment. On the 4th instant there were 1,064 new cases announced; 553 deaths, and 131 recoveries. On the following day there were 2,983 cases in the hospitals. At Moscow, from the 12th to the 19th of June, there were 1,724 new cases, and 728 deaths. On the 19th of June, there were 327 new cases, and 153 deaths. The number of persons labouring under the disease at Moscow on the 30th of June was 1,974. The cholera is also raging in several of the Russian provinces.

At Jassy, in Moldavia, from the 17th to the 28th of June, 1,799 persons had been attacked, of whom, 810 had died, 334 were cured, and 655 remained in the hospitals.

Some of the cases were so rapidly fatal that the patients died within four, and even two hours of the attack.

APPOINTMENTS.

M. Archambault, Medical Director of the Lunatic Asylum of Mareville, near Nancy, has been appointed Physician to the Asylum at Charenton, in the room of M. Foville, dismissed.

M. Chatin has been appointed Professor of Botany in the School of Pharmacy, Paris, in the room of M. Guiart, deceased.

William Bowman, Esq., has been appointed Professor of Physiology at King's College, London, conjointly with Dr. Todd. This appointment was made on the proposition of Dr. Todd, and the recommendation of the Medical Professors of the College.

John Hughes Bennett, M.D., has been elected Professor of the Institutes of Medicine in the University of Edinburgh, in the room of Dr. Allen Thompson, who has been appointed Professor of Anatomy in the University of Glasgow.

ROYAL COLLEGE OF SURGEONS.

At a meeting of the Council on the 13th of July, Edward Stanley, Esq., was elected President, and Joseph Henry Green, Esq., and James Moncrieff Arnott, Esq., were elected Vice-Presidents of the College for the ensuing year.

Gentlemen admitted Members Friday, July 14th:—A. Birney; R. Wilson; H. B. Robertson: E. Batt; T. English; T. Walker; J. T. Matthew; J. W. Crow; W. Scott; E. Ilott; J. Conry; J. F. Johnson; and T. M. Jones.

Monday, July 17th:—J. M. Todd; G. M. Young; T. S. Ludlow; G. W. Paternoster; T. S. H. Jackman; J. George; T. Roberts; W. C. Lake; G. Smith; J. Hinton; T. B. Rake; H. E. Turnour; and H. Turner.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, June 29th:—Augustus Robert Henry Padmore, Pilton, near Barnstaple; Thomas Rhys, Penlline, Glamorganshire; Samuel Nathaniel Squire, Pakefield, Suffolk; Eade Sewell, St. Oakley Hall, Essex; Alfred Drew Dunstan, Wadebridge; James Kingdon Luke, Week St. Mary, Cornwall; John Vacy Lyle, Launceston; Hugh Creolahan; Blackall Marsack, Barnstaple.

Thursday, July 13th.—Henry Llewellyn Williams, Beverley; Robert Edwards Jones, Long Melford; Henry Mervill Williamson, Chapel-in-le-Frith; John James Robert Robertson, Chelmsford; James Nuttall, Liverpool; Charles Wethered, Little Marlow.

OBITUARY.

Died, June 24th, aged 46, John M. Jameson, M.D., late of Enfield.

June 30th, at Cavan, Hugh M'Donald, M.D., Physician to the County Fever Hospital in that town.

July 2nd, at Tewkesbury, aged 57, Joseph Higginson, Esq., Surgeon.

July 3rd, at Headford, of fever, Mr. J. T. Oben, Medical Assistant to the Headford Dispensary.

July 4th, at Southampton, aged 28, James Claudius Paxton, M.B., only son of Dr. Paxton, of Rugby, and recently elected to one of the Travelling Fellowships on the Radcliffe Foundation at the University of Oxford.

July 9th, at Oxford, aged 53, Charles Webb, Esq., Surgeon.

July 14th, aged 47, of fever, Joseph Howell, Esq., Surgeon, Southwark Bridge Road, London.

BOOKS RECEIVED.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen having cases or other communications to read at the Anniversary meeting, are requested to send information of the same to the Secretary of the Association, on or before Wednesday, the 9th of August.

ROBERT J. N. STREETEN, Secretary.

TO CORRESPONDENTS.

Communications have been received from Mr. T. Crosse; Dr. C. Barham; Dr. Herapath; Mr. Newnham; Dr. Castle; Mr. Crompton; Mr. Whitehead; Mr. W. F. Morgan; Mr. T. Hunt; Dr. Soulby.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

ON DIVISION OF THE CICATRICES CONSEQUENT UPON SEVERE BURNS.

By James Whitehead, Esq., F.R.C.S., Manchester.

(The subjoined case was mentioned at the Annual Meeting of the Newton Branch of the Provincial Medical and Surgical Association, held at Newton July, 1847.)

Morbid contractions, the result of deep and extensive burns, are among the most unmanageable deformities which the surgeon is called upon to remedy. In instances where the whole thickness of the integument, together with its subjacent cellular expansion, has been destroyed to any considerable extent, and especially if the injury happen to have been inflicted upon parts naturally enjoying great sweep of motion, as about the large joints of the extremities, or the neck, the consequences are frequently of the most disastrous kind, the members or parts being, in many instances, incommoded to a degree rendering them worse than useless, accompanied with physiognomical disfigurement of a description often painful to look upon. Thus, the head may be bowed down, and permanently fixed upon the chest, or towards the right or left shoulder; the jaw may be immoveably depressed, and the lips held apart, subjecting the whole interior of the mouth to constant exposure, while the faculties of articulation and mastication are rendered almost useless; the eyelids may be prevented from closing upon the eye, the arm be bound down upon the side, and the forearm violently flexed towards the shoulder, so as to become little better than a mere incumbrance. It is not without a very humbling sense of the poverty of our scientific resources that one is forced to acknowledge moreover, how completely surgical art has hitherto failed to furnish an efficient means of remedying these unfortunate conditions, whether as regards its unavailing efforts at restoration of the maimed organs to even a moderate degree of usefulness, or towards improving the appearance of the seared and unsightly surfaces which cover them.

In accidents of the class now under consideration, the lost integument is replaced by a structure which necessarily possesses a very low degree of organic force, being, for a great length of time after its formation, little more than a mere protecting web, wanting in the adequate power to sustain the deeper-seated organs within their assigned limits, and deficient also in its capillary development. The natural consequence resulting from this absence of tonic resistance is, shrinking of the cicatrix, with simultaneous displacement of the subjacent organs, followed by deformity and disorganization to a degree commensurate with the gravity of the accident. These changes in the relation of parts do not usually occur immediately after the infliction of the injury, nor even during the continuance of treatment; they take place most commonly after the reparative process is considered to be complete, and appear to be owing, in some degree, to the abandonment of the curative measures at too early a period. For it generally happens, even in cases where the loss of substance is very considerable, that until the healing process is fairly effected—the parts having, up to this crisis, been kept in a quiescent state, and well protected by the artificial covering employed to promote reparation—no tendency to displacement is perceived; but so soon as the new surface is freely exposed to atmospheric influence, and the subjacent muscles resume their functions, the cicatrix begins materially to alter its dimensions. Its imperfectly-formed cells, unoccupied by adipose deposit, fall together, and speedily become obliterated, and the organizing process going on within it, is, comparatively speaking, arrested; for while its extent of surface is daily diminishing, a corresponding increase takes place in its thickness and density, and the new formation, scantily supplied with nerves and blood-vessels at this early period, soon acquires a textural condition peculiarly unsusceptible of further organic increase. The nature of the structures entering into the composition of the bands of cicatrix, for the removal of which it is the intention of this paper to propose a remedial measure, and the manner in which they assume their abnormal arrangement, may probably be better understood if the reader be first of all briefly reminded of the anatomical disposition of the parts more immediately implicated.

The aponeuroses of the human body form a very important appendage to the organs of locomotion. Long neglected, as Cruveilhier has noticed, by the early anatomists, or alluded to in a very cursory manner as existing in particular parts only, and in portions independent one of another, they were first studied in an especial manner by Bichat, who arranged them under the head of fibrous membranes, of which system they constitute the most considerable portion. Of late years, however, the minute examination of these structures has occupied the attention of several able anatomists, and their importance in a physiological sense, is now duly appreciated.

Regarded in their totality, the fibrous membranes form a perfect model of the body of which they constitute so important an element. Immediately beneath the integument they are everywhere present; they afford a lining to all the great cavities, and a protecting sheath to the organs contained within them, as well as to their prolongations, the vessels, nerves, &c., in their minutest ramifications; they extend processes from the superficial to the deep-seated parts, becoming inserted in an especial manner into the various prominences of the osseous frame, which they also surround in its entire extent. Were it possible to remove every other organ and tissue, leaving only the fibrous membranes *in situ*, the latter would form a perfect skeleton of the whole body, nearly equal in its dimensions with those of the original. Being subject to the same laws which influence other tissues in reference to organic development, as a consequence of healthy functional activity, these structures may be seen to the greatest advantage in vigorous, athletic individuals, and in parts which enjoy great extent of motion, as the extremities. Thus, in one possessing a well-developed muscular system, they are thick, tense, and of a glistening pearly whiteness; but become flabby and attenuated, with loss of their characteristic pearly aspect in feeble subjects, and those who have undergone emaciation by chronic disease. In carniverous animals they are remarkably strong; the interfascicular septa which, in the young, or in the domesticated of this species, appear but as thin cellular membrane, being in the adult animal, especially if untamed, replaced by a thick pearly-looking structure, manifestly fibrous. This transformation of cellular into fibrous tissue, proves the analogy which exists between the one and the other, in relation to their organization, their vitality, and their uses, (Cruveilhier.)

The aponeuroses of different regions form with each other one continuous expansion, although generally described as existing in distinct portions, each of which is denominated according to its form, situation, use, or some other attribute. Their extent, therefore, is commonly regarded as being limited by certain marks, palpable or imaginary, forming the boundaries of different regions, and which, for the purpose of facilitating description, are referred to as indicating the commencement or termination of particular portions of fascia. For instance, that which envelops the upper extremity, called brachial aponeurosis, may be said to commence above at the lower margin of the clavicle, the acromion and spine of the scapula, and the muscular boundaries of the axilla. From these lines of departure, the membrane is expanded, in variable thickness and density, upon the whole circumference of the limb, tightly embracing the muscles and tendons from the shoulder to the points of the fingers, and being firmly implanted in the various osseous prominences about the joints and into the shafts of the cylindrical bones. From the internal surface of this general investment, processes are detached, called intermuscular septa, supplying each muscle with its proper sheath; these again, are seen to furnish other more attenuated projections to surround the component muscular bundles, each constituent fibre of which is also similarly provided; the subdivision being continued to a degree of microscopical tenuity. Thus it is found, that each ultimate fibrilla of which a muscle is composed, possesses its *sarcolemma*, or proper tubular investment of membranous tissue, not unlike in its nature, probably, to that which is manifestly fibrous.

The general aponeurotic investment just described, is nearly void of elasticity, and is immoveably adapted upon the parts which it surrounds. But between it and the skin is another similar though looser tissue, called the superficial or subcutaneous fascia. This fascia, in which the subcutaneous vessels and nerves are embedded, is connected by its outer aspect to the skin, of the cell-work of which it is a continuation, and by its deep surface, through the medium of innumerable thread-like fibres, to that upon which it rests, but in such a manner as to allow considerable extent of movement of the one upon the other in most parts of the body.

In those injuries classified by Dupuytren, as burns of the fourth degree—namely, where sloughing of the skin and both layers of fascia leaves the surface of the muscles exposed, the organizable matter destined to form the cicatrix or new skin, is furnished by the vessels ramifying upon the intermuscular and interfascicular tissues, with each of which, consequently, it becomes intimately associated; the vascular, nervous, and cellular prolongations of the one being directly continuous with those of the other. It thus appears evident, therefore, that in the kind of contractions now alluded to, simultaneous displacement of the subjacent tissues is physiologically inevitable:—in fact, the cicatrix from the moment it first begins to shrink, drags after it all the portions of interfascicular tissue with which it has become inseparably connected, disturbing at the same time, to greater or less extent, the relations of the muscles themselves. The fibres thus raised forward, soon shew signs of increase both in thickness, and in power of resistance; the result partly of shortening in their linear direction, and partly of actual structural accretion. Each movement of the limb tends to augment the mischief, so that in process of time a thick, firm, unyielding band is found developed within the folds of the meagre integument, consisting of dislocated intermuscular fibres, which it is impossible to replace by any means hitherto known.

The procedure generally recommended for the prevention of these deformities, is to keep the limb or part in an extended posture, until the new skin be sufficiently consolidated to act as an efficient substitute for that which was lost. But this of itself appears to me altogether inadequate to the purpose. The only media which are alone capable of supplying the deficiency,—namely, an ample extent of good skin, and a firm fascial investment beneath it,—are still wanting, and must of necessity remain unsupplied; yet, although the power of reproduction be, physiologically speaking, very limited, there is little doubt that the substitute may be materially improved, both in texture and efficiency, by careful management during its formation. The practice generally adopted of allowing the cicatrix

to be freely exposed immediately after the healing process has been effected is, in my opinion, a great evil, as it effectually hinders all further efforts of the re-organizing function, which would probably proceed to a much greater extent than is usually seen, if the atmosphere were to be so excluded as to prevent for a time the formation of hard cuticle over the new surface, which has the effect of arresting increase of substance, in an outward direction at least, if not throughout the entire structure. In addition to the plan of keeping the part extended in a direction opposed to that of the contracting tendency, my belief is that the whole extent of the cicatrix should also be surrounded by an impermeable tissue, oiled silk for example, in such a manner as completely to exclude the atmosphere, and the new skin ought to be now and then smeared with an unctuous application, having occasionally in combination, as necessity may require, some irritating or stimulating agent, such as turpentine, or an essential oil. These measures ought to be continued, in severe cases, many months after the healing process is considered complete.

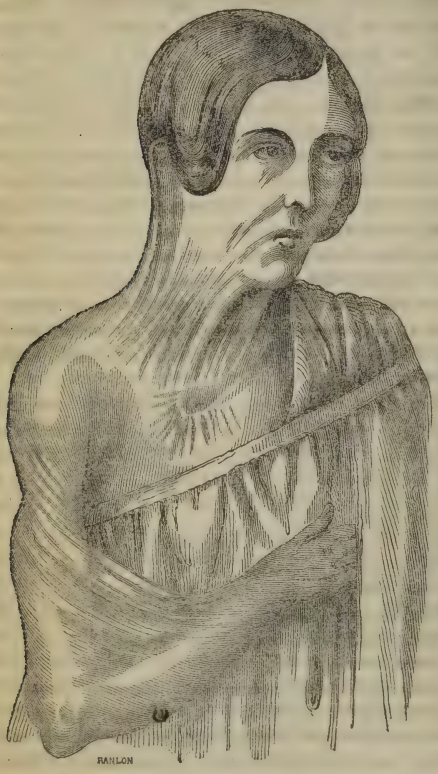
But my present purpose is to direct attention more especially to a means of restoring the use of parts disabled by the firm unyielding structures constituting the cicatrices already described, and which, in cases such as the one presently to be noticed, are productive both of serious functional inconvenience, as well as of great disfigurement. The almost uniform want of success which has hitherto attended surgical operations practised with a view to the relief of such deformities, has led medical men to regard them, for the most part, as irremediable cases; the removal or division of the abnormal structures having been generally followed by a state as bad as, or even worse than, that which it was attempted to remedy. Mr. Earle's plan of bringing the edges of the sound skin forcibly together, and securing their union, may possibly succeed in cases where the mischief is limited to a small space; but in extensive injuries, as for example where half the circumference or more of a limb is implicated, such procedure would be impracticable. The favourable issue obtained in the following case, which remains permanently relieved after the lapse of four years, has induced me to submit it to the notice of the profession, believing that the plan adopted in this, may be practised with a reasonable prospect of success in other cases of similar character.

Case.—E. B——, daughter of respectable parents, resident in North Cheshire, received a severe burn from accidental ignition of her clothing, in August, 1830, when *eight* years of age. The injury implicated a considerable portion of the left, the front, and the whole right side of the neck, extending from the ear, jaw, and occipital scalp, to the chest and axilla in front, and lower part of the shoulder behind; also the boundaries of the axilla, the whole circumferance of the arm at its upper third, and the entire half of the rest of the limb on its anterior aspect, from the last-named part to the hand. The left limb was also severely injured, but to a less extent. Twelve months afterwards, in August, 1831, the surfaces having been for a length of time completely cicatrized, the right fore-arm was found immoveably contracted upon the arm to the degree of an acute angle, in which posture it was maintained by a web of cicatrix extending between the distal extremities of the two portions of the limb, and occupying of course the whole intermediate space. The corresponding limb was similarly fixed, the displacement being, however, less considerable. She presented herself at the last-named date for the purpose of having the position of the limbs restored by operation. The skin of the neck was also deeply furrowed, and the head distorted, but an operation upon these parts was not deeemed advisable on the occasion in question. The cicatrices on the arms were accordingly removed, and the limbs maintained in an extended state by means of splints. A thick cord was tied round each limb at the elbow-joint, after a fashion long since recommended. Being at that time engaged in the pursuit of my elementary studies, I had an opportunity of witnessing from time to time the progress of the case. At the end of twenty-one weeks the cure was considered perfect, but in consequence of some degree of contraction being already manifest, the use of splints was ordered to be continued. Had this injunction been fully complied with, the issue would probably have been much more favourable than it proved to be. But once from under the actual surveillance of the surgeon, daily attention to the measures enjoined soon became irksome, even to the anxious parent, and the apparatus was not long afterwards abandoned altogether.

The contraction alluded to as existing at the time when the patient was returned to her friends, although but slight, was, nevertheless, not susceptible of replacement, even by the application of considerable force. But in twelve months after the operation, both limbs were again fixed in nearly the same position as before, and the right one rendered all but useless. Bands of cicatrix had sprung up nearly equal in extent with, and much more resistant than, those which had been removed, and the deformity, which was subsequently further aggravated, remained unrelieved for *twelve* years following.

In May, 1844, the patient, being 22 years of age, presented herself again to my notice. The parts exhibited the appearance represented in the accompanying engraving, made from an original sketch by a talented artist, Mr. G. W. Anthony. At this period the head was dragged downwards towards the right side in a very inconvenient and unsightly manner, the distortion in this part being in reality much greater than the figure appears to represent. The fibrous band subtending the angle at the elbow-joint, was equal in thickness to, and tangibly as firm as, the Tendo Achillis. The first operation was performed upon the neck, the incision commencing below the ear, the lower part of which organ was merged in the folds of the cicatrix; it was thence continued below the line of the jaw to a point opposite the middle of the chin. Division of the skin simply appeared to afford no relief whatever to the distortion, there being immediately beneath numbers of bands of a bright fibrous aspect, which effectually prevented the parts from resuming their natural position. These being successively divided with the bistoury upon a grooved probe, and the head raised, other sets presented themselves to view, which, when extended, still produced a tractive effect upon the cicatrix below.

Bundle after bundle was in turn dragged forward and divided, from one extremity of the wound to the other, until caution suggested a cessation. The wound, which appeared dreadfully large, was cleansed and covered with simple dressing; it was quite healed in four weeks.

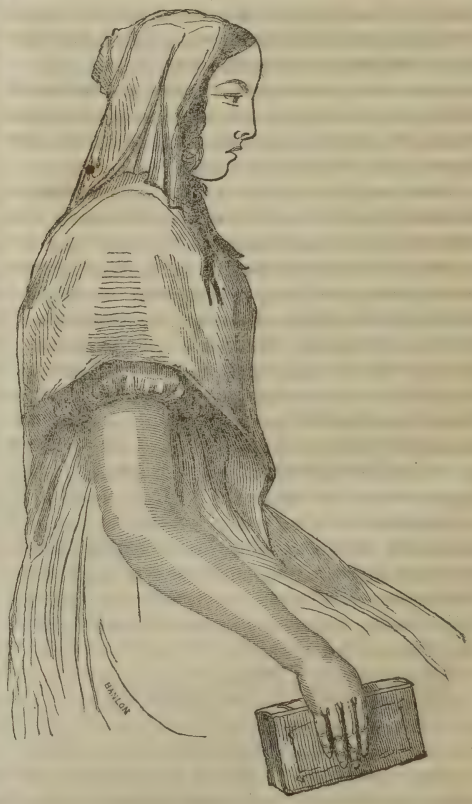


The relief afforded by the above operation encouraged confident hopes of a successful issue from a like procedure upon the arm; this was accordingly practised on the 8th of June, 1844. The bistoury was plunged through the structure at the angle of flexure, as close upon the joint as safety to the neighbouring parts would admit, and thence carried forwards, emerging at the free edge. But this incision, which might, *a priori*, have been looked upon as all that was necessary, constituted comparatively but a small share of the operation. The divided parts immediately retracted considerably; but when extension was attempted, even but to a limited degree, a number of shining fibrous bands started forwards completely hindering further movement. These were also divided and extension again attempted, when others of similar character were brought into view, occupying an elevated position in front of the joint, and opposing like resistance. In this manner successive groups of fibres had to be separated, layer after layer, before the limb could be brought into a straight line, which was not accomplished until all the deep-seated bands reaching across the joint on each side of the large vessels, and outwards towards the condyles, has been completely divided, including of course the fascial insertion of the biceps muscle. During the operation the median basilic vein was accidentally wounded; this, it was found necessary to ligature on each side of the puncture, before further steps could be taken.

The wound, which measured eight or nine inches in the long direction, and upwards of four inches transversely, was cleansed and covered with simple dressing and a bandage. A splint was applied to the back part of the limb on the fourth day, but this appeared unnecessary, as there was no difficulty in easily maintaining an extended position; the apparatus was altogether abandoned at the end of three weeks, and never afterwards required. The wound was completely cicatrized in six weeks.

About three months afterwards I divided, in a similar manner, the cicatrices bounding the axilla, on the same side of the body, with nearly equal success.

The accompanying engraving from a sketch made on the 30th of March, 1847, nearly three years after the operation, by the artist above-named, represents the state of the arm at that period, and its appearance now



is even still more favourable, the limb having become more rounded and fleshy.

The successful issue of the operation was undoubtedly attributable, mainly, to the *perfect* division of *all* the fascial fibres traversing the elbow-joint anteriorly from the arm to the fore-arm, or at least *all* that could be exposed with safety.

It is not a little remarkable that the elbow-joint, which had been almost totally unused for twelve years,

appeared in no way injured, as no pain was complained of, nor difficulty experienced, in the attempts that were made to move it. The limb is now plump and well shaped, and apparently as strong and useful as though it had not been materially injured.

OBSERVATIONS ON ANÆSTHETIC AGENTS IN SURGICAL OPERATIONS.

By George M. Humphry, Esq., F.R.C.S., Surgeon to Addenbrooke's Hospital, Cambridge.

(Read at the Annual Meeting of the Suffolk Branch of the Provincial Medical and Surgical Association, held at Bury St. Edmunds, June 16th, 1848.)

My experience in anæsthetic agents having been confined to æther and chloroform, the following remarks must be understood as applying to them, though the mode of operation of other substances of a similar kind which have been more recently brought into notice is probably much the same. I should likewise state, that my observation has been almost entirely limited to the effects of these agents upon the human body, the experiments on animals which I have seen being few, and not very instructive.

After a brief consideration of the *modus operandi* of æther and chloroform, I will proceed to state also briefly the results of my own experience as to their value in surgical operations.

There can, I think, be little doubt of the anæsthetic properties of these agents being due to a direct effect upon the nervous centres produced by them in consequence of the mixture of their vapour with the blood, which takes place in the lungs much in the same manner as the components of the atmosphere are added in the ordinary process of respiration. Travelling the round of the circulation, and carried into the capillaries of all organs alike, the influence of the vapour is first observed in the nervous centres, which we know from other experiments to be peculiarly susceptible of impressions made in this manner through the medium of the blood.

The complex organ or rather system of organs which we include under the denomination of nervous centres, ministers to a variety of functions. To the intellectual, the sensational or perceptional, and the volitional, by the cerebral hemispheres;—to the special senses and the emotions, probably by the corpora striata, optic thalami, and other ganglia, at the base of brain;—and to the reflex functions by means of certain of these ganglia, by the spinal cord, and by the medulla oblongata, the reflex functions most essential to the continuance of life,—viz., those upon which respiration and deglutition depend, being executed by the latter of those organs. These functions of the nervous centres have been enumerated above in the order of their liability to be interrupted by various agents affecting the whole system. A blow on the head may deprive a man of consciousness, and, as a necessary sequence, of volition; the persistence of a certain amount of sensation being often evinced by his resisting attempts to separate the eyelids, withdrawing his limbs from irritating causes, curling himself up into a comfortable position in bed, and even crying out lustily when hurt. In all this, being unconscious, he may have no perception of annoyances; in strict language, he may not feel them. A more severe injury is followed by total loss of sensation as well as of volition; the limbs lie motionless wherever they are placed, and the man exhibits no sign of discomfort from any irritation or impression of light or sound. Even some of the reflex functions are suspended, the iris and the sphincters cease to act, but the actions of respiration continue, deglutition is performed, and there may be vomiting. The effect of all this disturbance upon the heart, which is less directly influenced by the nervous centres, varies a good deal; sometimes its pulsations are slow, laboured, or intermitting, at others they are accelerated or continue but little altered. In these cases of cerebral injury, the different parts of the nervous centres are for the time paralysed by the direct effect of the shock or jar upon them; and they suffer in proportion to their delicacy or their susceptibility to such an impression. Happily, the parts which minister to the reflex functions most essential to life are the last to be affected.

In their general outline the symptoms of cerebral injury correspond with those produced by anæsthetic agents, though in the latter case the several portions of the nervous centres are paralysed, not at once by a rude shock, but gradually, one after another, by the application to them of a subtle and evanescent poison, which thus dissects or unravels, as it were, the functions of the brain, removing first one, then another, with a regularity and certainty we were not prepared to expect. Moreover, with both æther and chloroform, a period of excitement sufficiently distinct precedes the depressed or paralysed condition. The first few inhalations are usually productive of some cerebral excitement or wandering, with suffusion of the face and eyes, and acceleration of the heart's action; various sensations are felt, strange sounds, knockings and beatings are perceived, and stars or flashes of light are seen, which increase in rapidity till they are lost in silence and gloom; for these signs of excitement are soon followed by a depression or suspension of the cerebral functions, the loss of consciousness, of perception, and of volition, shewing that the hemispheres of the brain are yielding to the agent. It occasionally happens that volition is lost before perception and consciousness; thus, a gentleman who took chloroform by way of experiment, was aware of the pinchings, and pullings of the hair, which I inflicted on him, but could not move nor express that he was so. I was told that a young woman felt the key applied, and the wrong tooth drawn, without being able to intimate the mistake, or to offer resistance. More frequently common sensation is the first to yield, and the patient may watch the steps of the operation upon his own person, may comment upon them, may hear the scissors snap, or be conscious of the crash caused by the dislodgement of his tooth, without feeling pain.

Usually, sensation or perception, volition, and unconsciousness, are lost together, and an interesting period may now often be observed before the parts of the brain subservient to the emotions are paralysed,

during which laughter and crying take place, sometimes even to a violent degree, being unrestrained by the controlling influence of the mental powers. There may also be struggling, even violent struggling, requiring several persons to hold the patient, with delirium. These emotions and strugglings are sometimes the effect of the anæsthetic agent exciting the ganglionic, at the same time that it is paralysing the hemispherical, portions of the brain; or they may be the result of irritating impressions made upon the surface, as during the operation, and acting through the nerves upon the emotional part of the brain. Consciousness and perception are lost, but the emotions remain; for it must be remembered that the former are by no means essential to the latter, and that the exhibition of the latter is no evidence of the existence of the former. The patient partially under the influence of æther or chloroform may cry out, not because he perceives the pain of the operation, but because the emotional parts of the brain remain free, and easily excited, after the perceptional regions are paralysed. It may be sometimes that he feels and forgets the sensation, but no doubt it often happens that the emotion of crying is produced without the perception of pain actually taking place. It is of importance that we should be fully aware of this distinction, and remember, that so far as our patients' sensations are concerned, it is not necessary to press the anæsthetic influence to such extent as to quell the emotions.

If the inhalation be continued the emotions subside, and not unfrequently a clonic contraction of all the muscles is observed, a condition which the dentist has often found to baffle his attempts to open the mouth. This contraction will pass off, and the muscles again become released, as the effects of the æther or chloroform go off, and by watching the gradual subsidence of the anæsthetic influence, the operator may succeed in opening the mouth and drawing the tooth, without the consciousness of the patient. The contraction will likewise subside under the increased influence of the agent which produced it; the muscles now become released, and the reflex functions begin to give way. Probably the clonic contractions just described, and the quick deep inspirations which immediately precede this last state, are the result of the exciting influence of the agent upon the reflex system, which precedes its paralysing effects. If this be true, the order of sequence of the stages through which the patient usually passes, when submitted to the influence of æther or chloroform, is as follows:—First, excitement, followed by depression or paralysis of the mental powers, including sensation and volition; then, excitement and depression of the emotions; and, lastly, corresponding excitement and depression of the reflex functions. I do not mean to say that these stages can be clearly traced in each instance, or, indeed, that they are invariably present, but that the above is the order in which they usually occur.

When the last-mentioned stage has commenced,—when the iris ceases to act,—when the breathing becomes less quick,—when the head falls back, and the arms fall flaccid beside the patient,—more especially when snoring indicates that the natural reflex powers which preside over the upper part of the respiratory apparatus are failing, the operator knows that his patient has imbibed quite enough, and the inhaler should be removed. A further dose might irrecoverably paralyse that part of the nervous system (the medulla oblongata,) upon which respiration depends, and produce a fatal result. Happily the diminished frequency of the breathing which now takes place commonly prevents the further rapid inhalation of the agent, and induces the operator to remove the inhaler. But he will do well to desist before this point, and by repeating the dose as the effect wears off, to keep his patient in an anæsthetic state, short of that in which the reflex functions of the medulla oblongata are affected; for the symptoms of fainting and collapse which are apt to occur under such circumstances are sometimes very alarming.

I have considered the effects of these agents almost exclusively as they relate to the nervous system; for it is probable that the influence excited by them upon other organs is, for the most part, secondary, and the consequence of that produced upon the nervous centres. The action of the heart varies; it sometimes remains unaltered, either as to frequency or force, during the whole period of the inhalation; more frequently it is at first accelerated, and subsequently becomes depressed, slower, feebler, irregular, or intermitting, and occasionally it appears to stop altogether for a few seconds. Sometimes the depressing influence of the agent is evidenced at once; the pulse goes down during the first few inhalations, and may rise again as the state of insensibility comes on. In what classes of persons each of these varieties is likely to occur, I cannot tell, nor in what cases the depressing effect upon the heart's action may be most early expected.

The congestions of internal organs, the brain, and lungs, which have been observed in *post-mortem* examinations, and regarded as the cause of death, are more probably the result of impaired nervous influence, and the cessation of respiration, than of any direct effect of the agent upon the minute vessels.

As the anæsthetic influence passes off, the patient retrogrades through the stages of insensibility in the order corresponding to that by which they had advanced. A considerable period often intervenes between the recovery of consciousness and sensation, so that the patient is often holding conversation during the latter part of an operation, without evincing any signs of feeling. Sometimes he wakes up suddenly from a state of complete insensibility, and is quickly himself again; thinks he has been asleep, and is for some time occupied with the recollection of his dreams, rather than with his present condition, till, perhaps, his stump meets his eye, and he is astonished to find that he has lost a limb.

The difference in the effect of æther and chloroform depends upon the greater potency and more rapid influence of the latter, so that the several stages of insensibility are less clearly marked, and the complete state of anæsthesia more quickly induced by it. Its evanescence is correspondingly quick, and the after effects, the excitement, giddiness, headache, &c., are much less persistent. Indeed, the patient is commonly

so far recovered in a few minutes as to feel no remains of its influence. In the administration of æther we were anxious to produce the effect quickly, so as not to overload the system with the poison, whereby the period of recovery was prolonged. In the use of the more rapidly-acting agent, the chloroform, we endeavour to feel our way and are careful not to paralyse too quickly the several parts of the nervous system, for fear the influence should extend too severely to that segment upon which the continuance of life immediately depends. Happily the cases in which death has followed the employment of these agents in the human subject, have been too few to enable us to reason with much certainty upon them, but it has appeared that the fatal results from æther depended upon the long continued influence of the agent upon the brain which could not recover its natural energies, death occurring after a few hours or even days. But chloroform has killed by sudden and complete paralysis of the respiratory and circulatory forces, the patient dying in a few seconds.

I come now to the consideration of the practical value of these agents in surgical operations. This is a question to be decided by observation alone, for we must be unwilling to admit speculation upon a discovery which had taken us so much by surprise, and exceeded our highest expectation of it. Surely, by no previous discovery, except perhaps that inestimable one of vaccination, has so much pain been saved at so little cost. That we should be able to remove limbs and perform other grave operations without the infliction of pain, was a triumph too great for our belief. Still less could we imagine that an agent capable of producing such an effect would be unattended by deleterious or even fatal results in the indiscriminate use which was too likely to be made of it. Though I commenced the use of æther very early after its discovery was announced in this country, I must say I did so with much apprehension, and with great care. It was a source of no little anxiety to me, and I used to watch the weekly periodicals in the fear that they would soon teem with the records of fatal cases. Even at the present time, after the administration of æther and chloroform in a great number of cases during the last year and a half, I cannot forget that I am wielding a powerful and very dangerous weapon, which requires the greatest care and attention in its use.

I have witnessed the administration of æther and chloroform in some hundred cases, nearly all the operations of importance in our hospital having been performed upon patients subject to the influence of one or other of these agents during the last year and a half. The æther was used from Christmas, 1846, to October, 1847. Two patients, young women, one of whom suffered amputation of the toe, the other of the thigh, were excitable, hysterical, or delirious, and at times faint, during the remainder of the day, Two other women to whom æther was exhibited for slight operations were said not to have recovered their memory and the full use of their mental faculties for several days after. One lad died with peculiar symptoms of oppression of the sensorium, preceded by delirium, three days after amputation of the arm on account of accident. Æther was administered; its effect was quick and complete and soon passed off, so that he slept well and the delirium was not observed till the following morning: we cannot with certainty attribute the fatal result in this case to the æther. With these exceptions I saw no ill consequences from the inhalation of æther beyond, occasionally, headache, sickness, and giddiness, lasting for a few hours.

Since its introduction, chloroform has entirely superseded æther in our practice; we have been in the daily habit of using it during the last nine months, and I am not aware that its administration has been productive of any ill consequence in a single case. It is usually given on a small sponge fixed in a mouth-piece to prevent excoriation of the lips. The mouth-piece is not closely applied at first, so that some air is admitted in the early inspiration. A drachm of the fluid is poured upon the sponge, and additional doses of half a drachm are given as occasion requires. The best time for commencing the operation is when the muscular system is relaxed and the head falls back. The administrator should be careful to remove the inhaler directly any snoring is observed, and indeed he will do well to stop short of that point. The only formidable symptoms which I have witnessed from the administration of chloroform have been those of fainting. On one or two occasions these were rather alarming. Splashing the face freely with cold water was found to be the most effectual means of inducing re-action. I cannot tell what conditions of the system decidedly contraindicate the use of chloroform, but I should be unwilling to administer it to persons in whom fainting was likely to be attended with serious consequences,—such as old people, or persons with feeble or diseased heart, intermitting pulse, or disease of brain.

I have observed chloroform and æther to act exceedingly well on delicate and enfeebled persons, those very cases in which we have most to apprehend from the pain and shock of an operation; and the knowledge of this fact has induced me to recommend amputation in some cases where I should have been unwilling to submit the patient to the unmitigated pain of such a procedure.

Of the influence of chloroform in preventing the sufferings of the patient, during an operation, there can be no doubt, and if it do no more, it is a wondrous boon; but the more important question of its influence upon the ultimate recovery of the patient can be decided only by the carefully collected results of extensive experience. I can venture only to give my own impressions, which have gradually grown, from the observation of many patients, and which are decidedly in favour of the agent. Though quite prepared for occasional fatal accidents, during its administration, I believe that the average success of operations will be increased by its cautious and discriminate use. The shock to the system (a very important item in an operation,) is so closely connected with the pain felt during the time, and is so greatly lessened by the absence of pain under the influence of chloroform, that

in several instances, and those cases in which its effects were most to be dreaded, I have been unable to trace any of its usual consequences. There has been certainly, on the whole, less prostration followed by feverish re-action, after operations under æther and chloroform, than we used to witness before the introduction of these agents.

There seems, moreover, to be a connection between the pain felt during an operation, and that which is experienced in the wound afterwards; for you cannot have failed to observe the comparative freedom from pain which patients enjoy for some time after operations which have been performed under the influence of æther and chloroform; they often converse on other subjects, as though there were nothing the matter with them, and when placed in bed they are at ease, and, perhaps, fall asleep.

Beyond the benefits which result from the lessening of the shock of the operation, and the diminution of the pain for a variable period afterwards, I am not aware that æther or chloroform exert any influence, good or bad, upon the progress of the wound, or the ultimate recovery of the patient.

We have sometimes thought the oozing of blood from wounds, after the administration of æther, to be greater than under ordinary circumstances. It always ceased upon the application of moderate pressure, and secondary hæmorrhage very rarely occurred.

Though I cannot but regard the introduction of anæsthetic agents as a general improvement in surgery, I hope enough has been said to show that I am not without due sense of the danger that may result from them, and of the great caution required in the employment of such very powerful agents.

HISTORY OF A CASE OF POISONING BY PRUSSIC ACID.

By J. Bampfylde Daniell, M.D., Fellow of the Royal College of Physicians, and Senior Physician to the Bath United Hospital.

(Read at the Annual Meeting of the Bath and Bristol Branch of the Provincial Medical and Surgical Association, held at Bath, Thursday, June 22nd. 1848.)

Whatever tends, either as the result of pathological observation, chemical analysis in toxicology, or through medico-legal enquiry, to detect crime or vindicate innocence, cannot fail to be of interest to the members of the medical and surgical profession. It is with this view therefore, that I submit to this Society an account of the *post-mortem* appearances, chemical analysis of the suspected contents of the stomach, with some medico-legal observations on suicidal acts, committed in an irresponsible condition of mind, in reference to a case recently brought to my notice. Permit me to state, that I was present at the examination of the body, and at the subsequent chemical analysis of the contents of the stomach, both of which were ably and conclusively conducted at the Bath United Hospital, with the assistance of my friend and colleague, Dr. Davies, and our attentive House-Surgeon, Mr. Brace. I also attended the coroner's inquest.

Forty hours after death the examination commenced. The body presented strong muscular conformation; a livid patch over the posterior superior portion of the scapula extended to the coracoid process. The hands and mouth were partially closed, the usual effect when death is caused by prussic acid. There was an apoplectic resemblance in the eyes; no odour was evolved from the body; neither were there any external marks of violence. On dividing the scalp, fluid blood, perhaps more than usual, escaped; the vessels of the membranes of the brain were much injected, and the brain rather firmer than natural. On opening the lateral ventricles, the characteristic smell of prussic acid was observed by myself, Dr. Davies, Mr. Brace, and Mr. King; there was also a small cluster of hydatids in the fluid of the ventricles. The same odour was apparent in other removed portions of the brain. The lungs were healthy, but congested. The structure of the heart, with its valves and cavities was healthy. On reflecting back the muscles of the abdomen, there was observed an abundant deposition of adipose tissue, and before opening the abdominal cavity, a smell of prussic acid was again perceived; with the exception of the liver partaking of a slight tawny tint, the other viscera were healthy. On removing the heart and lungs, ligatures were placed around the upper portion of the œsophagus as well as at the pyloric opening, and the stomach with its contents carefully removed.

Near the cardiac extremity the mucous membrane of the stomach was vascular. The stomach was large, and contained about six ounces of pultaceous partly-digested food, smelling strongly of spirit. Some of the clearer portions of its contents were filtered and submitted to the action of three tests for the detection of prussic acid,—namely, "sulphate of copper, sulphate of iron and nitrate of silver." A portion of the filtered solution was subjected to the sulphate of copper test, when a greenish precipitate was thrown down, which was dissolved on the addition of hydrochloric acid. To a second portion, the sulphate of iron test was applied, and on adding dilute sulphuric acid, instead of the formation of Prussian blue, the greyish precipitate produced by iron, was re-dissolved. To a third portion the nitrate of silver test was used. A heavy precipitate fell, which remained unchanged on the addition of cold nitric acid, but was immediately dissolved on raising the acid to the boiling temperature. This might perhaps be considered open to a fallacy, as the fluid previous to being tested, had not been distilled, and probably contained animal matter. It was therefore deemed necessary to procure a distilled portion from the remaining contents of the stomach, by the employment of the water-bath, at a boiling temperature. This operation was continued for several hours, and strange to say, no distilled product was collected. Sulphuric acid was added to the fluid before distillation commenced.

It is probable that the cause of the prussic acid not passing over at the temperature of a water-bath, may be referred to the fatty matter contained in the ingesta,

which on melting formed a thick layer on the surface of the fluid, and thus the vapour of the acid was prevented escaping.

The following letters were received in reference to this point:—

"King's College, London,
"January 20, 1848.

"My dear Sir,—I fear I cannot give you any very certain answer to your questions; probably, however, your test with the filtered liquid from the stomach failed from the great state of dilution of the acid. When distilled, being very volatile, it came over in the first portions of the liquid, which thus was much more concentrated than the original solution, and so acted with the test.

"The reason usually given for employing a vapour bath is, that some organic substances in distillation furnish prussic acid though they contained none. Formiate of ammonia is one of these. I cannot say that the objection to the employment of a boiling heat seems to me a very serious one. No doubt you would have obtained the acid, however, by the employment of the water-bath, had you continued the operation, the only objection to this process being the greater length of time required, which, in such cases, ought not to be allowed to have much weight.

"Believe me, my dear Sir,
"Very truly yours,
"Wm. Allen Miller.

"J. H. Brace, Esq."

"Edinburgh, February 7, 1848.

"My dear Daniell,—In the process for obtaining hydrocyanic acid by distillation at a vapour-bath heat, from complex organic mixtures, it is recommended to add sulphuric acid to the suspected material before distillation. Was this attended to in your proceedings? for, if not, the poison may have existed in the form of hydrocyanate of ammonia, which may resist a mere vapour-bath heat, although ebulition may carry it over; or, may not the failure to obtain any acid by distillation without boiling have arisen from the heat not having risen sufficiently high around the retort or matrass, so that what rose from the fluid condensed above, and trickled back into the subject of analysis? for I have known this occur in other parallel processes of distillation.

"If you look again at what I have said, on the degree of heat and mode of applying it, you will see I am by no means so positive in prescribing ebullition as you seem to have thought (see pp. 755, 756, 4th edition,) nor is anything said derogatory to the spirit-lamp. In point of fact, the objection to the use of a distilling heat, on the ground of risk that intestine changes may thus be produced, with the effect of forming hydrocyanic acid in complex organic mixtures, is treated as a hypothetical one, and in practice I have been in the habit of disregarding it, boiling the suspected matter with a naked gas-flame, without fear of fallacy.

"Yours faithfully,
"R. Christison."

"15, Bloomsbury Square,
"January 17, 1848.

"My Dear Sir,—I have only time to express an opinion in favour of poisoning by prussic acid in the case you detail, founded partly on the details of the case, and partly on the test of "the odour." Your tests, however, are inconclusive when applied to the stomach before distillation. The best way to apply the several tests is by holding a watch-glass moistened with them over the mouth of a bottle containing the contents of the stomach, &c. If this do not give very decided results, you must distil, at a gentle heat, and test the distilled liquid. I would recommend you to get Mr. Taylor's "Toxicology," as containing the newest information, and if you have no chemist at Bath, to forward the matters for analysis in a sealed vessel, to Mr. John Bowman, or Dr. Miller, at the King's College; but, perhaps, the evidence at the inquest will dispose of all difficulties.

"Yours very truly,
"William A. Guy.

"W. H. Brace, Esq."

The same contents of the stomach were now submitted to the heat of a spirit-lamp, and distillation completed. A solution of the sulphate of copper being added to a portion of the distilled fluid, rendered alkaline by Liquor Potassæ, the usual green precipitate was observed, which, on the addition of hydrochloric acid was rendered white. A solution of sulphate of iron added to another portion, (also rendered alkaline,) threw down a greenish brown precipitate, which was re-dissolved by dilute nitric and sulphuric acid. This test was carefully repeated again and again, the same tests being applied to a solution of prussic acid, (rendered alkaline,) the characteristic blue colour immediately appeared. A solution of nitrate of silver in a third portion of the distilled fluid gave a dense white precipitate, which was insoluble in nitric acid, at a common temperature, but was dissolved when boiled.

The evidence of prussic acid was now established, although the quantity detected by the several tests was small and insufficient to account for death; but from the time that elapsed between swallowing the poison and the examination of the body, much might have volatilized. The blood was in a fluid state, indicative of death from prussic acid.

Before entering on the defence set up on the question of medico-legal enquiry, I may briefly relate the previous history of the case:—It appears that on the evening of the 13th of last January, two females passing up Dorchester Street, observed a man lying on the ground, and on going near him found him nearly lifeless, a slight gurgling noise in his throat being the only evidence of life. They immediately sought assistance, and by the help of two policemen removed him to the United Hospital. On being received it was found that he was dead; enquiry was made, and it was ascertained that the deceased was a surgeon, who *had left a widow and seven children:* the deceased had arrived from Chippenham by the night train, at which place he had stopped several hours, and drank at several inns; that latterly he had been in embarrassed circumstances, *which produced great depression of mind.* His mental disquietude was further established by the evidence of a police constable, who, on calling at the residence of the deceased, was met at the door

by Mrs. Spencer, who immediately exclaimed "Is he dead," and expressed her fears that she should hear of his destroying himself, every time he left home, as he *was so troubled in mind about his affairs.*

A druggist, residing at Chippenham, deposed that the deceased entered his shop about eight o'clock on the evening of the 13th, and asked for an ounce or an ounce and a half of prussic acid, but did not say for what he wanted it. Witness handed him an ounce bottle of Scheele's hydrocyanic acid. Deceased appeared as if he had been drinking. Witness had known him for three or four years, and considered him only an occasional customer.

The Counsel for the defence having in his cross-examination endeavoured to elicit something favourable to the supposition that deceased had died of apoplexy, or some such cause, a conversation arose between him and the Coroner, whether the evidence could lead the Jury to the conclusion that the deceased had committed suicide, and if so, the Counsel would request an adjournment, in order to produce evidence of unsoundness of mind. The Coroner commented on the evidence, and remarked, "Should the Jury consider death was caused by taking poison, *the next point* on which they ought to be satisfied, was the *state of mind* in which the deceased was prior to his death, and unless they had evidence that he was not sane, or was suffering from temporary derangement, the law allowed of no intermediate verdict, in what state of mind the deceased was there was no evidence to show; should there be no evidence of insanity, the jury must return a verdict of *felo de se*; at the same time, should they do that, it was not for him to inform them beforehand what would be the legal effect of such a verdict, as it respected property or life-insurance." The Jury having intimated that they had made up their minds as to the first point, desired an adjournment on the second, for the purpose of ascertaining by evidence, whether deceased *was of sane or insane mind.*

It was urged in the defence, that the deceased was of a plethoric habit, addicted to spirit-drinking; that British brandy (having drunk some shortly before his death,) sometimes contained essential oil of almonds; that there was no evidence to shew when prussic acid was taken; that if deceased had taken an ounce of Scheele's hydrocyanic acid at the Bath Station, he could not have walked from thence to the spot where he fell; (a case, however, is given in "Taylor's Medical Jurisprudence," of a person taking half an ounce of hydrocyanic acid, who had walked a similar distance;) that deceased being a surgeon, it was essential to his business that he should possess poisonous drugs; that very little prussic acid had been discovered in the stomach, and that *little*, insufficient to cause death; that the human senses were fallible; and that as odour presented no visible test, it was dangerous to place too implicit a reliance on it; that no bottle was found near the body,—a fact which Professor Taylor had remarked was seldom found to occur in cases of suicide from deadly poisons, so instantaneous in their paralysing effect as prussic acid is, to destroy the power of volition, by means of which the bottle or vessel whence it was imbibed could be flung to a distance; that the deceased was of a plethoric temperament, and constitutionally predisposed to apoplexy,—a disease simulating the effects of violent poisons.

Should the Jury, however, be of opinion that deceased had poisoned himself, the next question was, whether he had committed the act in a *sound state of mind or not.*

Evidence was adduced that deceased had first called at a druggist's shop where he had been in the habit of purchasing all his drugs for some years; that between six and seven o'clock on the evening of the 13th, deceased entered the shop and asked for an ounce of prussic acid, Scheele's strength. It was refused him, his manner being very strange, and his answers wandering. Witness had known him to be in embarassed circumstances, particularly during the last two years. Deceased soon left the shop. From his appearance witness believed he was in a deranged state of mind; he was far from being affected with delirium tremens; he was low, lost, and wandering.

The brother of the deceased also stated some circumstances, which confirmed the unsettled condition of his mind, and that deceased had given a bill at two months, for some trust-money, which he had appropriated to his own use, and which became due on the day of his death.

Dr. Daniell deposed that he had seen the brain of the deceased at the *post-mortem* examination, and found a similar condition of the brain and vessels with that of those who had died in an unsound state of mind.

The form of insanity under which the deceased laboured, appears to me referable to that which has been termed *moral mania*, as distinct from *insanity* of the intellect. Since the time of Esquirol, all the distinguished authorities in insanity have recognized this form of lunacy. In the one the moral sentiments are perverted; in the other the reasoning powers are overturned. These two forms of insanity may be observed separately, or in combination. We may see cases of *moral mania* in which the reasoning powers remain unaffected; and we may see cases of purely *mental mania* in which the *moral sentiments and the affections* are in a healthy state.

No one can observe the separate forms of moral and mental mania in a lunatic asylum without being able to trace their separate indications in mixed cases.

We cannot shut our eyes to the real existence of cases in which the tendency to crime is a disease which no self-control on the part of the individual can arrest. What must be contended for, is the distinction in criminal cases betwen the results of vice and disease. Let the laws of the country deal with vice, but let the victim of disease, or of that peculiar condition of disorder where insane manifestation is temporary, be handed over to medical care and superintendence. The great object is to ascertain where *vice* ends, and *disease* begins. That the two run into each other so closely, that the separation is difficult, admits of no doubt; but this should not prevent medical men from following out the truths of crime to their legitimate consequences.

In the case I have just related, there was no evidence of intellectual mania; professional business was attended to; medical directions were correct; there was no disposition to injure others; but the *res augusta domi*, pecuniary embarrassment, the unhappy and soul-thrilling reflection of the present, as well as future, circumstances of an affectionate wife and seven helpless children, crowded on his brain. His habits vary. He was addicted to stimulating liquors; self-control is destroyed, and *on the very day when his difficulties* chiefly pressed on him, he destroys himself. His self-control was lost by disease, and he required the control of others to guard and protect him.

It is a very strong ground for the extension of pardon to a prisoner, where all the members of the jury, who by the terms of their oath, are compelled to find him guilty, have concurred in recommending him to mercy.

In the case of the unfortunate Annette Meyers, not only did this recommendation run with the verdict, but we find that the Jury, before quitting the Court, reiterated their entreaty to the Chief Baron, that the life of one whom they term a guilty, yet deeply injured woman, may be spared.

Let us see the reasons the Jury assign for their recommendation.

After hearing the testimony of the witnesses delivered orally in Court, they arrived at the following conclusion:—"That she slew the man for whose murder she stands condemned," say the Jury, "admits of no doubt. The degree of deliberation, however, and premeditation used by her previous to the commission of the act, materially affects its nature. To make the slaying of a man 'murder,' there must be cool premeditation." The Chief Baron on the trial insisted on this point.

Now, the Jury in their letter to the Chief Baron, state that they find Annette Meyers guilty of *murder*, but without premeditation. They are of opinion that, *up till the very hour* in which the fatal act was committed, *her purpose was not fixed.*

"It was," say the jury, "the deliberate and atrocious contempt with which the guilty deceased treated the prisoner,—it was the last crowning act of cruelty and indignity, which drove her into a state of phrenzy and uncontrollable passion. In that moment of phrenzy she drew forth the pistol, and laid the worthless wretch dead at her feet. That she purchased the fatal weapon under the influence of strong feeling, there is no doubt; it might have been directed against her own life, or that of the deceased. It was the merest affair of chance which of the two should fall. She accosted him in the Park with no fixed intention of injuring him. The deliberate cruelty and determined baseness of the deceased at that moment, drove her to madness, and in her frenzy she slew him. The prerogative of mercy, therefore, is prayed to be extended to her."

I need not enter more fully on this important subject at present, as an opportunity will probably occur during the meeting of the Provincial Medical and Surgical Association, of offering my remarks in a more matured form, and collecting valuable opinions from those enlightened professional gentlemen whose views have been particularly directed to such subjects.

CASE OF PERMANENTLY SLOW PULSE.

By C. Barham, MD., Truro, Physician to the Royal Cornwall Infirmary.

(Read at the Annual Meeting of the South-Western Branch of the Provincial Medical and Surgical Association, held at Truro, July 16th, 1847.)

In the *Dublin Quarterly Journal of Medical Science*, for August, 1846, there is an interesting communication from Dr. Stokes, on the connection of permanently slow pulse with repeated cerebral attacks of an apoplectic nature, though not followed by paralysis. Dr. Stokes has directed the attention of the profession to the subject as one requiring further investigation, and not hitherto much attended to, and he has himself collected only seven cases, in which the above combination of cardiac and cerebral phenomena was well marked. On this account I have thought it desirable to place on record, a decided instance of the co-existence of these affections, although I am not furnished with the precise results of any physical examination of the heart during life, neither was a cadaveric inspection permitted.

A lady, aged 69, the mother of a large family, having risen from her chair, and moved towards the bed, fell forward on it, and almost instantly expired. She was at the time apparently recovering steadily, though slowly, from an attack of hemiplegia, following an apoplectiform seizure, which had occurred about six weeks before. Her usual pulse was 28 in the minute, but it had risen on the day of her death eight or ten beats, a circumstance which excited some apprehension in the mind of her medical attendant, who had visited her some hours before the fatal event.

The first decided cerebral attack occurred in Sept., 1834. Before this she was a remarkably good walker, and took a great deal of exercise in the garden, but from that date she was obliged to discontinue walking and stooping, which produced an uneasy feeling about the heart. The affection was decidedly apoplectic in its character, and life was considered in great danger for some hours, but the recovery was afterwards rapid and perfect, and there was no paralysis. A similar attack occurred in the following year, and another about Christmas, 1841. Sickness and gastric disturbance attended them all.

There were thus, altogether, at least four seizures of this kind. But in the intervals between these, her family were many times alarmed by the occurrence of what they designate "fainting fits," which came on especially after dinner, when she would often appear quite oppressed, and sometimes talk in rather an incoherent manner. This was more particularly the case towards the latter part of her life, when cupping on the nucha, which had always relieved her, was repeated about once in three months. On the last two or three occasions, however, the benefit derived from it was very transient; the blood was always thick and flowed tardily. She was often obliged to have recourse to aperients, but their action produced no effect on the head symptoms, or rather seemed to aggravate them. The appetite was always good. Cold weather increased the affection of the head, and occasioned her severe suffering. In her latter years the breath became very

short on exertion of any kind, so as to oblige her to stop several times in mounting a flight of stairs, and the feet and legs becoming œdematous, she was limited to carriage exercise. In her earlier womanhood she was subject to very severe headache, which recurred at intervals, and sometimes confined her to a darkened room for two or three days. The Bath waters were of more service than any other remedy in obviating these attacks, and she subsequently derived much advantage from the use of porter. This was exchanged for brandy and water about fifteen years before her death, and she habitually took this with her dinner and supper. Diffusible stimulants were also administered from time to time for the relief of the feeling of faintness. Depressing influences, physical or mental, were always injurious, and the more severe attacks appeared to be generally attributable to circumstances which had occasioned considerable grief or anxiety.

It will not, I think, be doubted, that the heart was the organ chiefly in fault in this case, which presents a marked similarity in symptoms and the effects of treatment to those detailed by Dr. Stokes.

Another instance of the same combination of symptoms, though the slowness of pulse is not equally extraordinary, has been mentioned to me by my friend Mr. Spry, in an elderly patient of his in this place, who has had an apoplectiform seizure without paralysis, and several attacks of transient leipothymia, and has been greatly benefitted by the use of brandy and water, now continued for two or three years. His habitual pulse was 50, and is now 56.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF PROFESSOR SANDS COX, F.R.S., SENIOR SURGEON TO THE HOSPITAL.

Reported by Peter Hinckes Bird, Resident Medical Officer.

Case II.

UNUNITED FRACTURE.

Joseph Roden, aged 22, painter, of pale anæmic appearance, was admitted into the Queen's Hospital, October 27th, 1846, under the care of Professor Cox. He states that about nine hours since he fell down from a ladder, and broke his arm. He was attended by a surgeon, who put the arm in splints. Has come from Weedon, a considerable distance, by railway, and must have necessarily been much shaken by the journey. The arm was found broken in its upper third; the ends of the bone were in good position.

November 14th. On examining the arm no union had taken place, nor was there any evidence of any callus having been thrown out. His health is good; appetite tolerable. The arm was well bandaged, and put into splints. On minute enquiry no syphilitic taint could be discovered. Extra meat. Mist. tonica.

Dec. 24th. No union has taken place, nor has any callus been thrown out. It appears that the lower end of the bone is drawn rather upwards and inwards by the action of the deltoid muscle. The ends of the bone were placed in the nicest apposition, and firmly rubbed together; the arm was then put in splints, and evenly bandaged. Appetite good; bowels costive. A pint of ale daily. Continue Mist. tonica. Pil. Extr. Coloc. Co. (Palmeri,) ij., pro re nata.

30th. The arm appears in good position; general health improved. To be made out-patient.

January 14th. The arm was examined this morning; the ends of the bone are pretty firmly united; health improved. An apparatus was contrived by which the fore and upper arms were retained at a right angle to each other, and the ends of bone kept in apposition by pads and light bandaging. R. Pot. Iodid., dr. ss.; Mist. Cascarillæ, Oss. Sumat unciam ter die.

29th. Firm union has now taken place, and he can raise his arm well; health continues good. Continue the medicine.

Feb. 8th. Can now move his arm well in all directions; the bone is perfectly straight, and its ends firmly knit. Discharged cured.

1. *A few remarks upon the circumstances under which fractures do not unite.*—The non-union of fractures sometimes happens from the anatomical structure of the parts, as when the neck of the thigh-bone is broken within the capsular ligament; in other bones it occurs from the want of proper apposition, from constitutional disorder, or disease of the bones themselves; sometimes from careless treatment, but more frequently from meddlesome conduct on the part of the patient. A piece of muscle may by chance get between the extremities of the bone, and prevent that apposition which is necessary for union.

2. *The most probable causes of slow union in this case.*—Continual disturbance of the parts was, in this case, the most probable cause of slow union, as the patient was constantly in the habit of undoing the bandage at night, and stating in the morning that it had slipped off of itself, or that it was too tight, and prevented him from sleeping.

It was the opinion of Mr. Cox that union would take place if the bones were kept in a state of perfect repose, and for this purpose the apparatus mentioned above was contrived; and there is no doubt that by means of the steady pressure, fresh action was induced, and the bones in a manner grew together, provisional callus on the outside being exceedingly small.

Case III.

INFLAMMATION AND SLOUGHING OF THE SHEATH OF THE TENDONS OF THE GREAT TOE: INFLAMMATION OF THE LYMPHATICS OF THE LOWER EXTREMITY.

Thomas Cole, aged 50, wood-turner, admitted Oct. 1st, 1846, under the care of Professor Cox. He states that about twelve years ago the second toe of the right foot swelled, and the sinew sloughed; about twelve months after the middle toe swelled and inflamed, which inflammation was followed by sloughing of the tendon; the sheath of the tendon of the fourth, and

afterwards of the little toe, inflamed and sloughed, two years intervening between each attack. Since these attacks he has lost the power of extending his toes; has had an ulcer on the foot for some time; attributes the present attack to lengthened exposure to wet and cold. About six weeks ago his great toe began to inflame, which inflammation was followed by suppuration, for which his toe was lanced.

On admittance the great toe of the right foot was found much inflamed, having two small ulcerations on its inner side, from one of which the extensor tendon protruded; he cannot extend the toe; the ulcers have an indolent appearance, and discharge a thin pus; general health good; bowels open; appetite good. To have a linseed poultice applied to the toe.

5th. The tendon has sloughed out; the inflammation is considerably abated; bowels rather costive. Extr. Col. Co., (Palmeri,) gr. x., statim. The wound to be dressed, and a bandage applied.

10th. Doing well; the wound looks healthy; does not complain of pain.

12th. Complains of pain all over the right leg; the pain commenced suddenly, and is described as sharp, gnawing; the foot is much inflamed and swollen; bowels costive. Pil. Calomel. cum Opio, quartis horis. Mist. purgans, oz. iss., cras mane. To have a poultice applied to the foot. Broth diet.

13th. The foot is still much inflamed, and the great toe is much swollen, and has a red and shining appearance; red lines are seen extending from the foot all up the leg; the femoral glands are much swollen, and are painful on pressure; there is some slight swelling and tenderness of the popliteal glands; tongue much furred; is very thirsty; pulse frequent and strong; no pain of head; the integument of the leg is much inflamed and hot; the redness disappears on pressure, but immediately returns. Appl. Hirud. xij. pedi; to be followed by warm fomentations. Lemonade. Mist. salinæ, oz j., quartis horis.

14th. The leech-bites bled freely; he feels better; tongue clean; bowels open; the inflammation is abating; the red lines are not so well marked; the femoral glands are not so painful, but are still enlarged to about the size of an egg; the foot is still inflamed and shining; the redness disappears on pressure, but immediately returns; the cuticle of the foot is desquamating. Linseed poultice to be applied to the foot. Lotio Plumbi to be applied to the leg.

15th. Better; the inflammation is abating; there is considerable discharge from the ulcer on the foot; the red lines are disappearing; the femoral glands are decreasing in size, and are not painful on pressure; the foot is shining and œdematous; tongue clean; bowels open. Meat diet.

16th. Doing well; inflammation of the foot subsiding; the red lines on the leg and thigh have entirely disappeared; the femoral glands are much smaller; general health improves.

21st. All appearance of inflammation has subsided; the swelling of the femoral glands has disappeared; the ulcer on the toe is nearly healed; health good.

28th. Discharged cured.

The lymphatic vessels, owing to their general and close distribution within, as well as between, all the organs of the body, necessarily take part in inflammation, constituting the disease termed angioleucites. From their simple structure, and their uniform reticular ramifications, they can rarely attain a distinct individuality, or be so substantially isolated from the parenchyma of organs, or even from cellular tissue, as to escape with the same frequency as arteries and veins, the influence of organic changes in the parts to which they belong. It is, therefore, only in unision with general experience, that Sömmering* insists upon this participation of the absorbents in the inflammation of every part of the frame.

The inflammatory process in the lymphatic vessels is originally developed in the contiguous cellular tissue, and from thence communicated in a reflex manner to the parietes of the canals. The vitiated contents of individual branches of the lymphatic vessels do not at once go into the larger trunks, and from thence into the general circulation, but have previously to pass through a series of glands, placed at various intervals from each other, and seeming to operate, to a certain extent, like purifying instruments; it thus follows that the consequences of a general diffusion of the morbid product, so serious in phlebitis, are here rarely to be apprehended. Having observed upon the slight susceptibility of the lymphatic vessels to irritation, and, as resulting therefrom, the comparatively rare occurrence of genuine inflammation of their tunics, it remains to inquire under what circumstances a septic inflammation is brought about. Velpeau assumes a peculiar disposition. A first condition, however, is that of liability to transudation of the morbid contents through the parietes of the lymphatic vessels. An exosmosis of this kind is induced, partly by the immediate action of the irritative matter upon the membranes of the vessels, partly by the clogging and distension of the latter, in proportion as the lymphatic glands become less permeable to the affluent lymph. This is abundantly confirmed by facts; for during life we observe that the lymphatic glands become turgid, whilst the course of the lymphatic vessels is indicated by a network of red stripes. These changes were well seen in the above case. After death the surrounding cellular texture is found to be the principal seat of the inflammatory changes; it is saturated with the transuding fluid, which, at an early period, is limpid, and of a pale red colour, but afterwards becomes turbid, either coagulating or being converted into pus. In the midst of this the lymphatic vessels may be recognized as thin knotty cords, their coats being thickened, especially in the vicinity of the valves, and about the point of the decussation of the individual branches. Externally they are milk white; their internal membrane, however, is of a pale red, and no longer smooth, but of a fine velvety aspect.

Inflammation of the lymphatic vessels and glands is observed as a sequence of very various and dissimilar diseases, but more especially of such as either result from the introduction of noxious, poisonous, or contagious

* De morbis vasorum absorbentium corporis humani.

substances, or as representing constitutional cachexia. Sömmering has enumerated a long series of disorders in all of which the lymphatic system is, in one way or another, primarily or secondarily engaged. In my opinion the inflammation was in this case induced by the absorption of acrid matter from the ulcer on the great toe. It is by a reference to the course which is pursued by the lymphatics that we are enabled to decide, almost at the first view, from a consideration of the figure and situation of the enlarged gland, whence the primary irritating cause has arisen. If, for example, the swollen and inflamed gland be situated just over Poupart's ligament, and more particularly if its greater diameter be disposed transversely to the direction of the long axis of the limb, then the swelling has, in all probability, been produced by some affection of the external genital organs,—a chancre on the penis, or the discharge of a gonorrhœa for instance; if, however, the tumour be situated lower down upon the front of the thigh, and its longest diameter be placed obliquely, and parallel with the course of the saphena vein, we may rest assured that the cause will be detected still lower down upon the limb, perhaps about the ankles, upon the heel, or between the clefts of the toes. In this case the cause was situated on the base of the great toe. Inflammation of the superficial absorbents of the thigh frequently ensues after contused and lacerated wounds of the leg and foot, and less frequently it is caused by the absorption of the acrid matter from ulcers. In the preceding case it was accompanied by very severe febrile disturbance of the whole system. If the disease be not quickly checked in its progress, it is often followed by diffuse inflammation of the subcutaneous cellular tissue of the limb.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, AUGUST 9, 1848.

It is related in the history of the Court of Bajazet, that this Sultan, whose career is replete with crime and dreadful excesses against the Christians, had condemned the judges of the country to death for bribery. Sinam, the tyrant's Fool, availing himself of a favourable moment, procured the dress of an Ambassador, and in that capacity desired to be sent to the Greek Emperor. "For what purpose!" said Bajazet. "To request some of his poor, miserable, bare-footed friars, for us to make judges of, now my dear lords are sent to prison." "I can," replied the Sultan, "supply their places with my own subjects." "We have none as learned in our realms," answered Sinam. "Well, well, you loved them," cried the Sovereign, "but they took bribes, and I will have their heads tomorrow." "'Tis just for that reason," said the Fool, "that I am going to fetch those silly Christians hither; none but such as they, who take an oath to starve themselves, will forbear the receipt of fees where no adequate salary is allowed."

It would seem that the authorities of the Poor-law entertain a similar opinion of the integrity of the members of the medical profession, who, though they may not absolutely have taken an oath to starve themselves, are yet considered to be the only persons who can be trusted to perform official duties without adequate remuneration.

But though we firmly believe, that, with perhaps a few unworthy exceptions, the Union Medical Officers will be found thus to have sacrificed themselves in the cause of suffering humanity, the sense of deep injustice cannot but remain *alta mente repostum*, rendering the performance of a sacred duty—the exercise of professional skill in behalf of the sick-poor—a source of annoyance instead of gratification, and pressing most where it is most efficiently and conscientiously discharged.

We have just received the able report of the Committee of the Convention of Poor-Law Medical Officers, too long, we regret to say, to be transferred to our columns entire. Every line of this document bears out to the full the complaints which individual members of the profession have from time to time made of the injustice inflicted on them in the working of the medical department.

"Although" (says the Report,) "the profession is sensible of the great defects in the present system of Poor-Law Medical Relief, almost every man affected by its operation, has hitherto been inclined to consider his own case, as special, and one of peculiar hardship; it is believed, however, that the facts obtained, and the inferences to be drawn from the labours of the Committee, will have the effect of merging all sense of individual grievance, into that of a deep feeling of general oppression and injustice."

The following extract from the Report on collating the returns made by the Poor-Law Medical Officers of no less than 805 medical districts is important:—

"By several of the returns, it appears, that on the issuing of the order of the Commissioners for the allowance of Extras, several of the Boards of Guardians, for the purpose of evading it, reduced the Salaries of the Medical Officers—others (a few only,) gently constrained the Medical Officers to compound for all extras, by a small fixed addition to the annual salary;—whilst others *have systematically and rigorously evaded it, by peremptory instructions to the Relieving Officer* to send all cases of accident, or cases requiring surgical operations, to the Hospitals to which the

Board subscribes. This is much complained of, not on account of the mere loss to the Medical Officer of the fees, only, but for the injury and risk suffered by the patient during the removal—sometimes in carts, over bad roads, for many miles."

The resolutions introduced into the House of Commons by Lord Ashley had, it appears, for a time, the effect of suspending the proceedings of the Committee with respect to their own plans. On these resolutions, however, being defeated and withdrawn, the Committee resumed their operations, and we now extract from the Report, as affording a summary of the remedial measures proposed, the heads of a scheme for carrying out the objects in view. These heads were submitted to Sir George Grey, prefaced by an appropriate memorial, explanatory of the evils existing under the present system.

1st.—"That in the opinion of your Memorialists, it is essential that the payment of Medical Officers should be by a fixed salary, exclusive of Fees for Midwifery and important Surgical cases."

2nd.—"That the amount of Salary might justly be fixed;—either by an estimate of the average of cases attended during a series of past years, considered in connection with the area of the Medical District; or by the payment of a certain sum per head on the population, corrected by the consideration of the relative density and poverty of the District.

3rd.—"That making every allowance for the difference which must exist in the remuneration of private and public practice, it would not be just that the Salary should be based on a less amount than 6s. 6d. per case, with the charge varying with the area.

4th.—"That Medical Officers of Workhouses should be paid a separate Salary, based on the average number of Inmates, at not less than 7s. to 10s. per head.

5th.—"That it is just and proper, and conducive to the interests of the Poor, that an extra payment should be made, as at present, for Midwifery and for important Surgical Cases; and that it appears to your Memorialists advisable that the Fees should be paid for cases occurring in Workhouses, as well as in Out-door cases.

6th.—"That to the cases of Surgery requiring payment, enumerated in the General Order of the Poor-Law Commissioners, should be added:—

Fractures of the Clavicle;—
Fractures of the Skull;—
Retention of Urine, when requiring repeated introduction of the catheter;—
Severe Burns and Scalds;—
And that £3 be paid for Compound Fracture of the Arm.

7th.—"That the payments allowed for Midwifery and Surgical Cases under the General Order of the Poor-Law Commissioners are satisfactory in amount.

8th.—"That in order to remove difficulties in the way of a more equitable payment of Medical Officers, and considering that half the Union Medical expenses are already paid from the Consolidated Fund, it is highly desirable that the whole expenses of the Medical attendance on the Poor should be removed from Unions to the Consolidated Fund.

9th.—"That it is expedient that there be a Director-General of the Poor-Law Medical Department appointed by Government, and exercising supervision over Poor-Law Medical Practice, in the manner of the other Public services.

10th.—"That it is expedient that there should be Inspectors-General of Poor-Law Medical Practice appointed by Government, and acting under the orders of the Director-General.

11th.—"That the Inspectors General acting each in a district assigned to them, should examine the Infirmaries of Workhouses, inspect the Reports of the Medical Officers, inquire into cases of alleged negligence, &c. &c., and that matters of disputed payment should be referred to them.

12th.—"That the Medical Officers of Unions should be appointed by Boards of Guardians as at present, subject to the approval of the Director-General; that their Qualification should be as at present ordered, but that all future modifications of the qualifications should be made by the Director-General.

13th.—"That the appointments of all Medical Officers should be permanent, that is, to endure until they die, resign, or are dismissed for some valid cause.

14th.—"That the Forms of Books or Reports should be approved by the Director-General, and should be as short and simple as is consistent with the requirements of the Public service.

15th.—"That the access of the Paupers to the Medical Officers should be made as ready as a due distinction between those who require Parochial attendance, and those who do not, will admit. That in doubtful cases where illness exists, and there appears to be temporary destitution only, the Board may grant Medical relief by way of Loan; that in such cases a Fee of be paid by the Board of Guardians to the Medical Officer."

Signed in behalf of the Committee,
THOMAS HODGKIN, M.D.,
Chairman.

4, Hanover Square, March 26th, 1848.

INQUIRY INTO THE TREATMENT OF BURNS AND SCALDS.

[The following communications have been forwarded by Mr. Crompton.]

CASES TREATED IN THE BATH UNITED HOSPITAL.

1, Circus, Bath, July 10th, 1848.

Dear Sir,—I send you the return made out by the House-Surgeon of the Bath United Hospital, by which you will see that various treatment has been employed; and you will see the proportion of deaths.

The opinion I have formed as the result of my practice in burns and scalds is, that each case must be treated according to its own peculiar circumstances,—that the constitutional treatment is the essential part,—that the local application is of minor importance; that which affords relief from pain is the best,—and that there is no real difference between a severe burn, and the destruction of the same extent of surface from contusion, laceration, or any other injury. Slight cases do not differ from the blister you produce by cantharides, and require only the same treatment. To

more severe and more extensive cases, I generally apply cloths, wet with cold water; or where a large extent of integument has been destroyed, cloths wet with warm water, frequently renewed. Opium, with stimulants, in the first instance, where the powers are much sunk, and strict antiphlogistic treatment afterwards; for I think the greater portion of deaths arise from inflammation of the throat, the pleura, or the peritonæum, according to the site of the injury. A severe burn over the throat and chest rarely recovers. Where the integument has been extensively destroyed, I dress the parts with ointment, in which there is spirit of turpentine, so soon as suppuration commences, and not before; and support the system with wine, bark, &c., so soon as the inflammatory symptoms have subsided. In this stage of severe burns it is that the patience, the care, and the nicety of dressing in the surgeon, will often make the difference between success and failure. The cleanliness, the early suppression of luxuriant granulations, the bandaging, the position of limbs, &c., will all tax the patience, and prove the ingenuity of the surgeon. I had a patient a year ago, in private practice, whom it took me two hours to dress; but for that care she would not have recovered. With these views you will see how difficult I should find it to answer the question of "What is the best treatment for scalds and burns?" I can only reply, shew me the case, and I will tell you how I would treat it.

I am, dear Sir, Yours truly,

To S. Crompton, Esq. GEORGE NORMAN.

TABLE OF CASES OF BURNS AND SCALDS TREATED IN THE BATH UNITED HOSPITAL,

(From January, 1846, to May, 1848.)

Date.	Sex.	Age.	Parts burned.	Result.	Discharged.	Treatment.
1846						
Jan. 1	F.	3	Chest and arms	Cure	Jan. 16th. 1846	Linseed oil and lime-water
3	M.	11	Abdomen (6 days)	Cure	Feb. 5th	Dressing on a granulating sore
25	M.	17	Legs scalded	Cure	Feb. 11th	Water-dressing
29	F.	12	Body extensively	Death	Feb. 6th	Linseed oil and lime-water, with wool
Feb. 20	M.	14	Abdomen and thighs	Cure	June 6th	Linseed oil & lime-water, &c.
21	F.	33	Face scalded	Cure	March 9th	Linseed oil and lime-water
March 17	M.	2½	Throat scalded	Cure	April 15th	Water-dressing
18	F.	5	Body extensively	Death	March 19th	Hot water
21	F.	54	Neck, arms and hip	Death from erysipelas	April 2nd	Linseed oil and lime-water
April 6	M.	3	Throat scalded	Cure	May 3rd	
6	M.	46	Back, arms, and leg, scalded	Cure	June 25th	Water-dressing
17	F.	51	Foot scalded	Cure	May 9th	Linseed oil and lime water
25	F.	18	Face and arms	Cure	April 30th	
June 17	M.	18	Face and hands	Cure	June 30th	
19	F.	18	Foot scalded	Cure	June 27th	
Sept. 13	M.	40	Foot scalded	Cure	Sept. 19th	
Nov. 3	F.	22	Body extensively	Cure	Feb. 12th, 1847	
5	M.	9	Body extensively	Death	Nov. 5th, 1846	
7	M.	8	Body extensively	Death	Nov. 9th	
20	M.	17	Legs and arms scalded	Cure	Jan. 4th, 1847	
20	F.	10	Chest and arms	Cure	Mar. 29th	
30	M.	10	Body extensively	Cure	Feb. 1st	
Dec. 10	F.	40	Chest and arm	Death	Dec, 11th, 1846	
21	F.	31	Feet	Cure	Mar. 26, 1847	
26	F.	11	Arms and neck	Cure	Feb. 10th	
1847						
Feb. 15	M.	8	Arms and side	Cure	March 1st	
April 2	F.	27	Leg	Cure	May 3rd	
13	F.	19	Chest and arm	Cure	May 10th	
Oct. 25	F.	16	Face scalded	Cure	Nov. 2nd	
Nov. 10	F.	24	Shoulder and arm	Cure	Feb. 21st, 1848	
24	F.	4	Thigh, leg, and chest	Death	Dec. 23rd, 1847	
Dec. 27	F.	55	Body very extensively	Death	Jan. 2nd, 1848	
28	F.	2	Legs	Cure	Feb. 11th	
1848						
Jan. 5	F.	27	Body very extensively	Cure	April 19th	
10	M.	3	Body	Death on the same day		
24	M.	8 mths.	Leg	Cure	March 2nd	
Feb. 28	F.	12	Chest and arms	Death on the same day		
March 31	F.	16	Perineum and thighs	Cure	April 10th	
May 15	F.	8	Legs and right arm	Cure	May 24th	

In all severe cases, as where the integument has been destroyed, the parts burned are freely painted over with a mixture composed of equal parts of linseed oil and lime-water, and then covered with cotton wool; these applications are renewed occasionally until the sloughs separate, when the granulating surface is dressed in the usual way, and the granulations are kept down by caustic and careful bandaging.

In less severe cases the cure is effected solely by the use of cold applications.

CASES TREATED IN THE ROYAL CORNWALL INFIRMARY.

Truro, July 5th, 1848.

My Dear Sir,—The following is a statement of burns and scalds treated at the Cornwall Infirmary within the last three years, which our Assistant House-Surgeon, Mr. Gorringe, has drawn up at my request. Though the house contains only forty beds, it is rather difficult to account for the smallness of the number of cases. It is, I presume, mainly attributable to the moderate population of Truro, (about 12,000,) and to the non-existence of those employments which call mothers away from the charge of their children. In the mining districts around they are differently circumstanced, but the nature of the accident would usually prevent the removal of the sufferer to any great distance. You will take the return as an evidence of good will, though it be like my little tract,—a very trifling contribution to the store of facts from which you will deduce inferences as to treatment.

Believe me, dear Sir,

Yours, with much esteem,

C. BARHAM.

S. Crompton, Esq.

TABLE OF CASES TREATED IN THE ROYAL CORNWALL INFIRMARY,

(Admitted during the last Three Years.)

Age.	Sex.	Interval between accident and death.	Interval between accident and recovery.	Situation and Cause of Injury.	Treatment.
Yrs.					
7½	F.	10 days	——	Her clothes caught fire. The parts involved were the arms, hands, neck, and face, with a few patches of raised cuticle upon the chest	Linseed oil and lime-water soon after the accident. The next day brought to the Infirmary, when *flour* was used. She did well until the sixth day, when inflammation of the lungs came on, and caused death. No *post-mortem*, as a few hours before death the mother removed her home. Small doses of carbonate of ammonia appeared for a time to do good.
30	M.	——	2 wks.	Scalded leg from boiling water	Spirit of turpentine.
36	M.	——	4 months	Fell with one foot into a trough containing the strong oil of vitriol at the Arsenic Works, Bissoe-Bridge. He had a thick lace-up boot on, and worsted stocking, these were so charred, that on withdrawing his foot they remained in the vessel. Deep ulceration followed, principally over the neck of the foot	Flour for a long time, and then red wash, (sulphate of zinc lotion.)
23	M.	——	2 months	Fell with one hand and arm into melted tin	Lapis Calaminaris, and afterwards the cerate.
16	M.	——	2 months	Clothes caught fire, and burnt both legs	Flour, afterwards the wash.
9	M.	——	2 months	Pinafore on fire. Burnt the chest and neck. Was treated at home, and admitted at the Infirmary for the contraction remaining after the cicatrization, the chin resting upon the upper part of the sternum. The integuments were divided, and the head kept back by a circle of wood fitting to the head, having attached behind a flat long piece of board, which was made to come as low as the scapulæ, and fastened by straps in front of the chest.	Relieved.
16	F.	——	3 months	Burnt neck and chest, and treated at home. Admitted for the contraction after cicatrization, the chin resting upon the sternum; the parts were divided as in the last case, and the same kind of instrument used.	Relieved.

Proceedings of Societies.

NEWTON BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

A Council Meeting was held at Newton, June 29th, Sir Arnold Knight, M.D., of Liverpool, in the chair, when the following members of the general Association were admitted members of this Branch:—C. R. Hall, M.D., Holmes Chapel, Cheshire; J. D. Price, Esq., Standish, Lancashire; S. Crompton, Esq., Manchester; T. W. Christie, Esq., Knotty Ash, Liverpool; at the conclusion of which, the business of the general meeting was proceeded with.

The members present were—Edmund Lyon, M.D., Wm. Chas. Bell, M.D., John Hatton, James Whitehead, Samuel Crompton, Manchester; Sir Arnold Knight, M.D., G. C. Watson, M.D., Liverpool; T. W. Christie, Knotty-ash; Henry Johnson, Walton; John Burrows, Liverpool; J. M. Robinson, Bolton-le-Moors; George Dagleish, Wigan; C. R. Hall, M.D., Holmes Chapel; A. O. Leete, Newton-le-Willows; Thomas Gaskill, St. Helen's; John Sharp, Warrington; J. D. Price, Standish.—*Visitors*:—John Hall, Congleton; Joseph Rogerson, Wigan; Alexander Shaw, Surgeon of the Middlesex Hospital, London.

The Secretary then read the following Report of the Council.

REPORT OF COUNCIL.

It has been usual for the retiring Council to present a report to the Annual Meeting. On the present occasion your Council have but little to report.

The Branch has within the last year suffered a great loss by the deaths of some valued and old members, to have to record which, is a very painful task; for, your Council have not only hereby to lament over the decease of fellow members of one common fraternity, but many have, at the same time, to deplore the loss of personal and endeared friends.

Dr. Holme, of Manchester, who died November 28th, 1847, in the 78th year of his age. He was, in fact, one of the founders of the Branch, if not the actual parent of it; he ever took a lively interest in the progress, harmony, and successful results of the Newton Branch, and never was absent from its Annual Meetings from the foundation, until the pressure of declining years and the inroads of ill health restricted his enthusiastic mind from those personal exertions in behalf of the objects of his profession, which had ever delighted him, for which he was ready to make any reasonable sacrifice, and which returned back into his own bosom their grateful fruits. His talents and acquirements, his public career of usefulness, his private worth, will form the theme of some biographic sketch which will find its way to the proper quarter—the Annual Meeting of the Parent Association to be held at Bath.

Dr. Kendrick, of Warrington, has fallen too, full of years and of respect, like his friend and fellow, Dr. Holme. The reaper put not in his sickle, till the corn may be said to have been fully ripe, and had already begun gracefully to bend somewhat under the golden freight of many a summer,—within two days of each other, and neither cognizant of the fact of the other having been summoned by the angel of death,—these two excellent practitioners sank, it may be said, together. It is sad, that even in these favoured and harmonious meetings, distanced from each other as they are by the intervals of yearly revolution, so many records of death's doings or threatenings should have to be made; but though your Council could have rejoiced in brighter subjects, and in many senses happier topics, yet they feel a satisfaction,—they cherish this last privilege left, that of noting down (no small or unimportant portion of their duty,) how great and good men fall at their post.

A third member of this Association, and one much respected, has paid, what is commonly called, the debt of nature. Dr. Howard, one of the physicians to the Royal Infirmary, Manchester, has been snatched off in the prime of life, and in the midst of a large sphere of useful and honourable labours. He fully appreciated the extensive importance of these fraternal gatherings, and often brightened the social interchange of kindly feeling and friendship nurtured by these re-unions.

A fourth fellow-member has been pressed, by the infirmities of years, to leave the field of duty,—it may be said, "Another standard-bearer fainteth!" When the name of Dr. Jeffreys, of Liverpool, is mentioned, all will admit that one of such untiring zeal and intrepidity is to be lamented, in his retirement from the active duties of his vocation, and that zealous co-operation and support which, whilst in health, he was foremost in affording, towards every cause which had the welfare of his own profession, or of his fellow-creatures, for its object. He was systematic, punctual, and indefatigable, in the representation of the local body, as its chairman. He was President of the Parent Association, when it honoured Liverpool with its annual visitation, in 1839.

This report ought not to be closed without a passing notice of the fact, that our indefatigable collaborateur, Dr. Duncan, of Liverpool, so extensively known and esteemed for his most able pamphlet some few years ago, "On the Physical Causes of the High Rate of Mortality in Liverpool," has received his appointment (under the sanction of the Secretary of State,) of Medical Officer to the Corporation of Liverpool, at a salary of £700 a year, whereby he will, in his official connection with the town under the New Sanitary Act for Liverpool, be able to render efficient service to the township by his personal attention and direction. His entire time and talent has thus been required for the public service, on those fair terms of remuneration which are satisfactory to himself, and also to his professional brethren, who could not but view, in his position, that of the rightful recognition, or the contrary, of the medical profession in its ability to serve the public by advice and services, so much required for the prevention of public ill health, and those services, in his person, duly honoured with adequate remuneration. Thus, on the notorious battle-field of ill-ventilated, over-crowded, badly drained, and, until now, misguided Liverpool, has the Legislature chosen to wrestle with this fearful group of physical evils, systematically and energetically, by adopting the alone means whereby the future health and interests of the town may be better provided

for and secured, than in the notorious by-gone years, whose fatal doings have passed the modern Tyre into a proverb.

It is to be hoped that the voice of the profession in commendation of this, the first Government step in the direction so imperatively demanded by the circumstances, and the waste of human life, may prove an encouragement to still further extension of the sanitary provisions to the whole country, whereby the waste of life annually equal to the loss experienced in many battles, may be saved by a measure which more truly—more correctly than by all its other conduct put together—will merit for the late and existing Cabinet, the honourable appellation of a paternal Government.

Further remarks on this and other correlatively important heads your Council does not venture upon, as its objects since the fusion of the once independent Newton Association with the Provincial Medical and Surgical Association, as a Branch of the latter, restricts the scope of the Branch to limited, and more properly, local objects. Still, your Council takes much pleasure in referring, before concluding its labours, to the zeal, ability, and persevering industry which the parent Association has manifested in its Council proceedings, watching over the interests of medical science and economy, and advising with the Government and Collegiate bodies, and the whole family of Provincial Practitioners, for the better security of interests common to all, and which it concerns the public, no less than the profession, to have definitely, wisely, and finally settled.

Through the instrumentality of the Parent Association, the Provincial Practitioners have at length acquired something like the power and the priviledged advantage of thinking, feeling, and acting, as one man. By this unity of action, the result of many laborious efforts, and well devised plans,—by many unselfish and generous-minded practitioners (several of whom have been called away ere the chief result have been won,) yet, by this unity, a promise is daily unfolding itself that the scattered, —the "*disjecta membra*" of the fraternity of physic, shall be ultimately re-cast in a mould capable of giving to them those fair proportions, relatively towards each other and the state; without which they must continue to present that anomalous and perplexing,—that often injurious feature, which results from the legislation of an earlier and less enlightened age, when war distracted the state from balancing its internal economies, having never been touched by a master-hand, and re-modelled in more just accordance, and useful subserviences, to the present state of society.

The Report having been read, it was unanimously resolved

On the motion of Dr. Hall, of Holmes Chapel, seconded by Mr. Whitehead, of Manchester, "That the Report of the Council now read, be adopted and transmitted to the Secretary of the Provincial Association for publication in the Journal."

On the motion of Dr. Lyon, of Manchester, seconded by Mr. Robinson, of Bolton, "That the thanks of this meeting be given to the President, Mr. Wilson, of Manchester, and to the Vice-presidents, Dr. Dickenson, of Liverpool, and Mr. G. M. Hardy, of Warrington, for their services during the past year."

On the motion of Mr. Burrows, of Liverpool, seconded by Mr. Crompton, of Manchester, "That Robert Thorpe, Esq., Surgeon, of Manchester, be elected President, and Dr. Kendrick, of Warrington, and Mr. J. Armitage Pearson, of Woolton, Vice-presidents, for the ensuing year, in accordance with the nomination of the Council."

Moved by Mr. Dagleish, of Wigan, seconded by Dr. Bell, of Manchester, "That the thanks of the meeting be given to the Council, for their services during the past year, and that they be requested to continue them."

Moved by Dr. Lyon, seconded by Mr. Whitehead, "That the thanks of this meeting be given to the General Secretaries, Mr. Hatton, of Manchester, and Dr. Watson, of Liverpool, for their services during the past year."

Moved by Dr. Lyon, seconded by Mr. Hatton, "That Charles William Bell, M.D., Manchester; Peter Pincoffs, M.D., Manchester; Thomas Hodgson Watts, M.D., Manchester; Frank Renaud, M.D., Manchester, be nominated members of the Parent Association, and also of this Branch."

Moved by Mr. Crompton, seconded by Mr. Dagleish, "That the next annual meeting be held in Manchester."

Moved by Mr. Crompton, seconded by Mr. Burrows, "That a sub-committee be appointed to revise the laws of this Branch, not only as respects the local arrangements of the Society, but its relation to the parent Association, and that such sub-committee consist of the following gentlemen:—Sir Arnold Knight, M. D.; Edmund Lyon, M.D.; W. H. Duncan, M.D.; R. W. Scott, M.D.; John Sharp, Esq.; Samuel Crompton, Esq.; John Burrows, Esq.; W. J. Wilson, Esq.; and the Secretaries, John Hatton, Esq., and G. C. Watson, M.D."

The Secretaries here reported the following members of the Branch, as having declined to continue their connection with it, viz.:—Francis Archer, John Cheesborough, G. H. Harbord, John Nottingham, Liverpool; Wm. Tinker, Hyde.

During the past year, the following members have died:—Edward Holme, M.D., James Kendrick, M.D., R. B. Howard, M.D., Mr. Gaston, St. Helen's.

MEMOIR OF DR. KENDRICK, OF WARRINGTON.

The following Memoir of the late Dr. Kendrick, of Warrington, was then read:—

Died, November 30th, at his residence, Warrington, Lancashire, aged 76, James Kendrick, M.D., F.L.S., the father of the medical profession in that town. He was born in Warrington, as were also his father and grandfather, and had spent the whole of his long and useful life in his native place. He received his early education at Burtonwood, a village, distant a few miles from Warrington, where is a small endowed grammar school, and from thence he proceeded to the free grammar school, in Warrington, then under the mastership of the Rev. Edward Owen, a man of the highest classical attainments, and the learned annotator of a well known edition of Juvenal and Persius," with which gentleman in after years he continued on terms of the closest intimacy. On leaving school he was articled to Mr. Hawkinson, of Warrington, a practitioner in surgery of some note in his day, and with him he passed the probationary course

of the profession. He first commenced practice in Warrington, as a surgeon, which he successfully continued many years, until maturer age induced him to seek the higher branch of medicine. During the early part of Dr. Kendrick's career, he enjoyed peculiar advantages in the society into which he was thrown. He had the good fortune to become personally acquanted with Howard, the philanthropist, who made Warrington his residence for several months in each year, during the latter portion of his life, for the purpose of superintending his various works which emanated from the press in that town, and he continued on terms of intimacy with him until his death. The assistance rendered by Dr. Kendrick in illustrating the period of Howard's life, above referred to, is acknowledged by his biographer, Dr. Brown, in his memoirs of that great and good man. The celebrity of the Warrington press had made that town, moreover, the resort of many other literary personages about the time named. Roscoe, Pennant, Doctors Aiken, Enfield, Percival, Ferriar, and a host of other writers might be mentioned, whose works were published towards the close of the last century, at Warrington, and into whose society Dr. Kendrick was by that means introduced. Amid this atmosphere of learning and science, his mind thus became imbued with a taste for literary pursuits, which continued to the close of life in its full vigour, and manifested itself at all times in the advancement of the means of intellectual improvement in his native town. Dr. Kendrick was on terms of cordial friendship and co-operation with the leading members of the medical body, and although his position as a practitioner in a country town prevented his name attaining more than limited fame with the world at large, his reputation stood deservedly high with the heads of his profession. The late Dr. Holme, of Manchester was one of his earliest and warmest attachments, as were also Dr. Rutter, and Mr. Park, of Liverpool, and the eccentric but talented Abernethy. He saw these bright ornaments of the age pass one by one from life, surviving the last and dearest, Dr. Holme, so short a space that he was spared the knowledge of his death. Endowed by nature with a remarkably robust constitution, he was able, even on the day of his death, to undertake his professional duties; and his anxious wish, as often expressed by him, "to die quietly at the close of a day's work," was literally fulfilled. He was devotedly attached to his profession, although, it is well known, it was not his original choice, and he attained in it an eminence, honourable, as it was his just desert. At the outset of his career, Dr. Kendrick evinced an untiring application and perseverence in the duties of his calling, which soon brought him into notice, and speedily led to the establishment of an extended practice; and when in after years he made way for the more active energies of junior practitioners, his clear understanding, sound judgment, and profound medical knowledge, ever inspired the greatest confidence in his skill. For the long period of half a century, at least, he may be truly said to have possessed, in an unexampled degree, the confidence of those with whom he lived, and in liberal and humane practice, he may be safely recorded as having indeed few equals. Conscientious in the extreme, his professional brethren bear testimony to the uniform integrity of his conduct, and throughout his long career, no act of his it is believed, incurred the slightest suspicion. Christian benevolence hsone forth as a prevailing trait in Dr. Kendrick's character, and as its fruits, there exist many local charities and institutions which derive their origin and support from him; to the cause of literature and science, as has been already observed, he was ever foremost to lend a helping hand.

In the year 1811 he succeeded, with a few others of congenial taste, in establishing the first literary and scientific institution in Warrington, of which he was chosen vice-president; and recently, in 1838, he joined in the formation of a society for promoting the study of natural history, of which he was president at the time of his death. He devoted himself at an early period to botanical study, which he cultivated with ardour through life, and he attained to superior knowledge and skill in the science.

As a companion, Dr. Kendrick was at all times agreeable and instructive; possessing a well-stored mind, powerful memory, and of a remarkably accessible and communicative disposition, his society could not be otherwise than attractive, and he has left a large circle of acquaintance, young as well as old, with whom his rich conversational humour, and fund of anecdotal wit, will long remain in pleasing recollection, and by whom his loss in social life cannot but be much felt.

On the day of Dr. Kendrick's interment, which took place at the parish church, on the 6th of December, every possible mark of respect, public, as well as private, was shown to his memory. The shops and other places of business along the streets through which the funeral passed were all closed, and his remains were followed to their resting place, not only by the corporation and other public authorities, but by all the principal inhabitants of Warrington and the neighbourhood, the members of the medical profession acting as pall-bearers. Dr. Kendrick was married and has left issue two sons, (the elder of whom, James, is also a physician in Warrington,) and several daughters. There is a clever portrait of the deceased gentleman in the possession of his family, of which a lithograph was published a few years back, and a copy of the portrait is about to be made for the purpose of remaining as a public memorial of him in the Warrington Dispensary, which institution he was mainly instrumental in founding, and to which he was at all times a most valued friend and supporter.

Foreign Department.

ON DROPSY IN PREGNANT WOMEN.*

By MM. Devilliers & Regnault.

(Translated for the Provincial Medical and Surgical Journal.)

DROPSY ASSOCIATED WITH ALBUMINURIA.

The study of dropsy in the pregnant female, associated with albuminuria, is surrounded with difficulties, inasmuch as we have not only to regard the subject of albuminuria itself, but have also to consider the numerous and important questions connected with the state of pregnancy.

* Continued from page 328.

We shall study together, dropsy with albuminuria in its simple form, and in its complication with convulsions; the latter being, in reality, one of the consequences of the disease.

Predisposing Causes.—Among the various changes wrought in the system of the female by pregnancy, those which are impressed upon the blood deserve the first consideration. In three cases of dropsy with albuminuria, in which the blood was examined, no very remarkable alterations were discovered, excepting in the quantity of albumen, which was greatly diminished, (from 61.34—56.39,) the ordinary proportion being 68.6. The water, on the contrary, was increased, (812.46—828.85, instead of 800.62.)

We have never been able to accomplish the discovery of urea in the blood, as has been done by Christison, Gregory, Rees, &c.. We explain this by the fact that our cases were in the incipient stage. All that we have been able to ascertain at present is, that the elimination of albumen by the kidneys has a powerful influence on the composition of the blood, and this materially favours the occurrence of serous effusion.

The age of the patients affected, does not in our experience offer any interest as regards predisposition. Temperament appears to have more influence, as all our cases were lymphatic females. A previous state of feeble health does not predispose to this form of dropsy; but the existence of the disease in one pregnancy, renders its recurrence probable in future ones.

Occasional Causes.—Those writers who have closely investigated the history of Morbus Brightii, regard vicissitudes of temperature, moisture, &c., as frequent precursors of the disease. We have not been able to verify this observation and the same remark has been made by Lever and Cohen. M. Rayer, however, attaches great importance to these agents. Insufficient food may possibly have some influence in the production of the disease, but we have in vain sought for evidence of the great influence attributed by English writers to intemperance.

Some authors explain the occurrence of albuminuria during pregnancy, by the compression of the ureters and renal veins, by the gravid uterus. We do not deny the fact, but we think the opinion open to discussion. Were this the case, albuminuria would be far more common in pregnancy than it is.

It remains for us to enquire whether the diseases which accompany gestation or are induced by it, have any influence in the production of albuminuria. One class of diseases in particular is thought to induce dropsy with albuminuria, as is well known,—viz., the lesions described under the denomination of "Morbus Brightii," "granular degeneration," and "nephrite albumineuse." We hope to be able to determine what amount of weight ought to be attached to this opinion.

Symptoms.—In the study of the symptoms of this form of dropsy, it is necessary to establish three divisions. 1st, the characters and progress of the serous infiltration; 2nd, the albuminous excretion; 3rd, the complications.

Precursory Signs.—Dropsy with albuminuria, in pregnant women, is sometimes preceded by giddiness, fainting, &c., which disappear when the infiltration is established, but in many other instances no such premonitory symptoms are recognized, the dropsical effusion being the first to attract attention.

Invasion and Progress. 1. *During Pregnancy.*—It is necessary to remember that albuminuria may occur in pregnant women without any dropsical accumulation. When the latter symptom does declare itself, it may be at very different periods. Thus we have known it commence with pregnancy, and also to show itself in other cases at the third, fourth, fifth, sixth, seventh, and even as late as the ninth month. The same diversity has also been remarked by M. Rayer and Dr. Lever.

In a small number of instances the dropsical symptoms have appeared suddenly, attaining a considerable development in a short period of time, but in the larger proportion of cases they are more chronic in their progress. The infiltration ordinarily first shows itself in the ancles, but often subsequently appears in the face.

2. *After Labour.*—As a general rule, this form of dropsy, however severe it may have been, disappears within a few days of delivery, seldom remaining beyond the tenth day, often departing as early as the third.

The distinctive character of this form of dropsy, is the presence of albumen in the urine, as may be ascertained by appropriate tests. In ordinary cases the symptom is not observed as an accompaniment of pregnancy, although M. Becquerel has advanced a contrary opinion. Other writers have stated that albumen may be found in the urine of females soon after delivery, but we have reason to suspect some error in their observations.

It is impossible to determine at what period the urine first becomes albuminous, because some œdema of the ancles is so common an affection of the pregnant state, that women do not complain until the affection has been of some standing. The quantity of albumen has never appeared to be in proportion to the amount of dropsical effusion; we have only been able to ascertain that it increases during labour, and rapidly diminishes after delivery.

MEMOIR
ON THE LOCALIZATION OF SKIN DISEASES.*

By M. Baron.

(Translated for the Provincial Medical and Surgical Journal, from the Gazette Médicale, April 1847.)

DISEASES OF THE HAIR-FOLLICLES.

Lichen.—Lichen simplex is a chronic inflammation, with hypertrophy of the cellular tissue immediately surrounding the hair-follicle. When the disease is of long standing, the tissue of the skin becomes dry and indurated, and the perspiratory tubes, in consequence, are obstructed or obliterated.

* Continued from page 389.

Favus.—The opinion is now pretty general that favus is seated in the hair-follicles. According to M. Baudelocque the follicle secretes a peculiar matter, which fills its cavity, concretes, and eventually by distending the duct points upon the surface.

M. Biett considers favus to be an inflammatory affection of the glands which surround the hair at its exit from the skin in the first instance, and that it subsequently invades the bulb, in which case the hair is entirely destroyed, and baldness ensues.

Alopecia is of two kinds. The first depends upon disease of the hair-bulb, as atrophy, &c; the other is due to a defect in secretion, or obliteration of the hair-duct, so that although the hair is regularly secreted, it cannot gain exit.

Calvities depends upon modification of the colouring matter, or obliteration of the central canal of the hair itself.

DISEASES OF THE CELLULO-FIBROUS STRUCTURE OF THE SKIN.

Ecthyma.—Many dermatologists range this among the diseases of the follicles, but the author believes it to be located in the cellular tissue of the derma. The same seat is attributed to rupia.

Variola, Varicella, Vaccinia.—These are all inflammations of various degrees affecting the same tissue.

Furunculus is the same, engaging the deeper cellular tissues, and causing death of a portion which forms the core.

DISEASES WHICH IMPLICATE SEVERAL TISSUES AT THE SAME TIME.

Scabies.—Many writers have treated of itch under the several varieties of papular, vesicular, and pustular itch, and Biett affirms on the contrary, that itch is essentially a vesicular disease, and that the papules and pustules are complications. The author does not admit any of these views, but affirms that the only pathognomonic feature is the presence of the little canal or track made by the acarus. The presence of vesicles, papules, &c., are secondary, and depends upon the character of the portion of integument upon which the insect makes its attack. Some of the complications are also due to the medications used.

[The above is a condensed sketch of the classification approved of by M. Baron. In as far as it is founded entirely upon anatomical considerations, it differs from most preceding writers on dermatology. Our countryman, Mr. Erasmus Wilson, has, however, taken the same ground, and with much better effect; but, as is usual with our French neighbours, the author of the above memoir is unacquainted with, or purposely avoids allusion to, the labours of the British pathologist.]

General Retrospect.

ANATOMY.

ON THE NERVES OF THE LIVER.

The liver is supplied with nerves from various sources, such as the left pneumo-gastric, the semilunar ganglia, and the right phrenic nerve, branches from all which enter the transverse fissure. Dr. C. H. Jones has examined the ultimate ramifications of these nerves, and ascertains that a large number of nerves are distributed to the coats of the portal vein, forming trunks, which subdivide and unite with other branches, so as to form a plexus with elongated meshes. In following further the course of the smaller branches, it is remarkable how great a distance they run. A small branch of 1-1500 inch diameter, separates from the main trunk, and runs along the coats of the vessel for a distance too great to be measured. The nerve may again unite with others, so as to form plexuses; or in other instances the structure of the nerve-filament becomes gradually less and less distinct, and the nuclei fewer, until it can no longer be discerned. The supply of nerves to the hepatic arteries is arranged much in the same way, but they are more numerous. With respect to the termination of the nerve-filaments, Dr. Jones is of opinion, that both in the arteries and portal veins, they form terminal loops, but of this he is not absolutely certain. The coats of the hepatic veins are more sparingly supplied; in some no filaments are perceptible. The ducts also seem to have but few nerves.

Respecting the structure of the nerves of the liver, Dr. Jones states that they consist almost entirely of the fibres, termed by Henle gelatinous, with which a few cerebro-spinal tubercles are intermingled.—*Medical Gazette*, July 15.

PATHOLOGY & PRACTICAL MEDICINE.

ON THE HYGIENIC INFLUENCE OF CUTTING THE HAIR.

Medical men are occasionally asked whether it is proper to cut the patient's hair; whether, in fact, this operation has any influence upon the health. M. Fredericque resolves the question by giving the following illustration:—

A little girl, aged 3, of good health in general, had her hair grow excessively long during the course of a few months. She was a beautiful child, but had latterly wasted without any apparent cause, becoming dull and apathetic, losing her appetite and strength without any organic lesion being discernible. There was an anæmic bruit in the carotids. She was placed upon a tonic regimen, with chalybeates, but without deriving material benefit, until her hair was cut short, at the suggestion of a friend, from which time she rapidly gained strength.

It would appear from this case that the economy had suffered a loss in the expenditure of blood necessary for the secretion of the abundant crop of hair. M. Fredericque considers that it is the formation of the colouring matter which chiefly exhausts the blood, as this is formed at the expense of the hæmatosine.—*Annales de Societé d'Emulation; Revue Médico-Chirurgicale.*

VENESECTION OF THE RANINE VEINS IN ANGINA.

An Italian surgeon, M. Ceglie, professes to have derived much advantage from this mode of bleeding in diseases seated in the throat. He explains the success upon the anatomical distribution of the blood-vessels.

He states that he has seen great benefit even in the acute stages of inflammatory croup, the symptoms of oppression, the agitation, suffocative cough, &c., ceasing almost instantaneously.

To perform the operation, the tongue is to be drawn forward, and after puncturing the veins, the mouth is to be frequently gargled with warm water. The bleeding may be repeated three or four times in the twenty-four hours, if necessary.—*Gazetta Toscana delle Scienze Medicofiseche.*

PHARYNGEAL POUCHES.

The following cases may be read with advantage in connection with an interesting example of the same disease, published in this Journal (see *Provincial Journal* for 1846, p. 402,) by Mr. Worthington:—

Mr. G. S., after some affection of the tonsils and uvula, eight years ago, placed a pepper corn in his mouth, which suddenly slipped backwards and lodged in his throat. It remained there about a week, causing great irritation, but was eventually dislodged. He has even since been aware of the temporary lodgement of foreign bodies in the same situation, but has not felt anxiety upon the subject. Gradually these lodgements seemed to increase, and large bodies became arrested in their course, the secretion of saliva becoming profuse. About two years since the uvula was excised, by which the complaint was much aggravated.

At the present time the patient is compelled to fill the pharyngeal pouch with soft solids, to the extent of two ounces, before he can get any food to pass into the stomach. He can at any time eject the contents of the bag.

In a second case, in the person of a bishop, now deceased, the affection came on imperceptibly, and could not be traced to any particular cause. The contents were often spasmodically expelled, and the breathing was occasionally interfered with.

Mr. Dendy, the narrator of these cases appends the following remarks:—

As to the anatomy of these curious cases:—The pouch, I believe, usually dips down between the œsophagus and the vertebræ, occupying, in fact, the place of the œsophagus, which is pressed against the trachea, and suffers attenuation of its coats from this compression. It is also strained or puckered by various degrees of traction, constantly increased, of course, by gravitation and the weight of the ingesta. This at length forms a valvular communication between the pouch and the œsophageal canal, immediately below the cricoid cartilage in front, and opposite the fifth or sixth cervical vertebra behind, thus not only impeding or entirely obstructing deglutition, but even preventing the introduction of a bougie or hollow tube, through which aliment might be admitted into the stomach, unless the relative position of the cavities be distinctly understood.

Now, what are the especial tissues which constitute the pouch?

May we not place the cases to which I have referred in the same category with those diverticula or pouchings, not only of the intestines, but of those other tubes which are frequently submitted to the influence of contraction and dilatation.

The lodgment of foreign or indigestible bodies will sometimes pouch the stomach itself. Amongst other persons, Dr. Baillie saw a capacious pouch thus and therein formed, which contained five halfpennies.

The cells of the colon are often immensely distended by scybalæ, especially in young women, although apparent regularity of defæcation may have averted the slightest suspicion of such a state.

Although the etiology may differ, we may adduce, as analogies, those dilatations found above the contractions of tubes, whether by spasm or thickening of coats. We may refer to the bulging abscess and infiltration behind urethral strictures; to the bagging of the bowel, when its calibre is diminished or contracted; and I may express my belief, that many cases which have been considered to be merely stricture, are indeed closely allied to those with the recital of which I commenced my observations.

And does the bag consist, or not, of the entire pharyngeal tissues?

I believe that it may consist of thickened mucous membrane only, and that continued and progressive pressure (as in the lodgment of a body in the sacculus formed by the rather sudden contraction of the pharynx, into the œsophageal tube, increased by the effort of severe conghing, especially when combined with pulmonary disorder, as in the case of my present patient and the bishop,) may have actually split or separated the muscular fibres of the canal, thus constituting a hernia of the mucous membrane analogous to the formation of true aneurism from muscular effort, or, perhaps, more nearly allied to those cases of double bladder, one of which is recorded in the last volume of the *Transactions* of the Medical Society. The coats of gastric pouches are usually much attenuated, and that not from inflammation or ulceration, but from mere mechanical pressure.

Now, on the assumption that many of these interesting cases may have been mistaken for œsophageal stricture,—a simple contraction of canal,—we may confidently point to one probable cause of difficulty or failure of the introduction of the bougie, in consequence of the *valvular orifice* (for such, indeed it may be termed,) of the œsophagus, and the constant slipping of the bougie into an artificial cul de sac. A point in practice may hence be adduced. In cases of difficulty, it would be well to place the patient nearly on his back, so that the pouch may rest on the spine, and then to press the bougie forwards on the trachea, at the same time uplifting the trachea itself. If the existence of a pouch be determined, the same plan should be adopted, and this immediately after the emptying of the pouch.

Regarding the permanent relief or obliteration of these bags, I cannot yet speak practically. I contemplate, however, the employment of a canula and sponge, slightly wet with a very strong solution of nitrate of silver, if the symptoms of my present case should, by their aggravation, warrant this proceeding. At the same time, I should impart nutrition as much as possible, or altogether, through the elastic tube introduced

into the stomach, so as to close the mouth of the pouch, and put it, as it were, out of office.

I believe that relief might be ensured on one or other of these principles,—either the shrinking or contraction of the bag, by its being kept empty and compressed, or by the adhesion of its sides, so as to produce complete obliteration; for although the mucous membrane is not so prone to adhesion as the serous tissue, we have very sufficient analogies to warrant that it might ensue in such a case.

CAUSE OF THE FATALITY OF INFLAMMATION OF THE UPPER LOBE OF THE RIGHT LUNG.

M. Hervez de Chegoin has for some time had his attention drawn to the peculiarity of the symptoms, and the especial danger, of pneumonia attacking this part of the lung. Such patients speedily exhibit all the signs of exhaustion, a very small pulse, a death-like pallor of countenance, peculiar disturbance of the intellectual faculties, nausea, and diarrhœa. Some complain, too, of intense pain in the clavicular region; the expectoration and cough are very slight, and crepitation is speedily exchanged for a dull *souffle*. The general and local signs of the inflammation are in fact very slightly displayed, although it almost always proves fatal. An autopsy of such a patient, which recently occurred to him, he thinks throws some light upon the matter. Examining the organs exactly *in situ*, he found, although the patient had lived thirteen days, the upper lobe was only in the first stage of hepatization, and that this now firm body exerted great compression upon the *vena cava superior*. This, he conceives, may explain the slow progress of the disease, the small pulse, the peculiar cerebral disturbance, &c. If this view be correct, instead of being deterred from bleeding these patients by their apparently exhausted state, our measures should be only the more vigorous; as the only chance of relief is the removal of the engorgement of the lung, which, by compression of the vein, impedes the circulation.—*L' Union Médicale*, No. 63.

SURGERY.

NEW MODE OF TREATING DEAFNESS ARISING FROM DESTRUCTION OF THE MEMBRANA TYMPANI.

Mr. Yearsley (*Lancet*, July 1,) mentions a simple means of remedying the loss of the membrana tympani with which he became accidentally acquainted through the instrumentality of a patient. This consists in inserting a small portion of cotton-wool moistened, into the meatus, and passing it with a probe to the site of the missing tympanum. He relates two very astonishing instances of the improvement in hearing thus accomplished. The remedy is a simple one, and its usefulness or fallacy will doubtless soon be amply ascertained.

TREATMENT OF ERECTILE TUMOURS.

M. Behrend, of Berlin, treats these tumours by the application of the concentrated acetic acid, followed by lint dipped in distilled vinegar. Under this treatment the tissue becomes pale and hard, diminishes in bulk, and is at length completely thrown off. He also, in some cases, enjoins the repeated division of the dilated vessels, by puncturing them with a needle with double-cutting edges.—*Journal fur Kinderkrankheiten.*

RESECTION OF THE SCAPULA.

W. ———, aged 32, was admitted into King's College Hospital, January 13th, 1847. He had suffered from disease of the right shoulder-joint for seven years, when the extremity was amputated at the articulation, at Fort Pitt Hospital, and a part of the glenoid cavity was at the same time removed. He recovered, but became the subject of abscess on the front of the chest about twelve months afterwards. On admission into King's College Hospital, the whole shoulder was enlarged, and the soft tissues hypertrophied; a great many fistulous openings existed in the pectoral region, and over the clavicle, which discharged copiously. Having determined on the propriety of removing the scapula entire, Mr. Fergusson proceeded to operate on the 6th of February, 1847. The patient was put under the influence of æther, and the clavicle was first exposed, and divided about two inches from its acromial extremity, with a saw; another incision extended along the spine of the scapula; and a third in the course of the old cicatrix. Some further dissection, and a division of the attaching muscles, enabled the operator to complete the excision, the subclavian artery being the while compressed over the first rib. The axillary and other arteries were tied, and the wound was closed with stitches. The patient's recovery was satisfactory, and unattended by anything deserving particular notice. On May 5th he was sent into the country, and a recent account reports him to be well and fat, though still occasionally troubled with small abscesses on the breast. After maceration the bone exhibited a hypertrophied condition; the remaining portion of the glenoid cavity was carious, and its margin was surrounded by a mass of new ossific matter.

MIDWIFERY.

HERNIA OF THE UTERUS.

Hysterocele is stated by Mr. Bell, to occur under three forms:—1. Through the inguinal canal. 2. Through the crural ring. 3. Through a separation or rent in the abdominal walls.

Two cases of the latter are recorded by him.

1. Mrs. P., delivered of her fifth child eight days previously. When seen she was collapsed, with quick small pulse. She complained of intense pain in the abdomen; on examining which the uterus was found protruding through a rent in the linea alba. It was reduced, but the patient died. No inspection allowed.

2. In a female, confined for the fourth time, after the birth of the child the uterus was felt to have escaped through a rent into the linea alba, and containing another fœtus. The membranes were ruptured after reducing the uterus, and the second child was speedily born. This woman did well.

Cases of inguinal and crural hysterocele are narrated by Sennert, Lallemand, Chopart, and Thurat.

The treatment of ventral hysterocele, consists in reduction, bandaging, and the recumbent posture.—*Monthly Journal*, July, 1848.

INTRA-UTERINE PERITONITIS IN THE FŒTUS.

Dr. Simpson exhibited at the meeting of the Edinburgh Obstetrical Society a fœtus, which had evidently laboured under peritonitis, as was evidenced by the effusion of lymph on various parts of the peritoneum. He believed that the disease was more frequent than is suspected, as he had discovered its traces in many fœtuses which had died in the seventh or eighth month of utero-gestation.—*Monthly Journ.*, May.

MATERIA MEDICA.

GUTTA PERCHA IN WOUNDS.

Gutta percha may be readily dissolved in bi-sulphuret of carbon in all proportions, and without the aid of heat. When a few drops of this solution are placed on the surface of any object, the carburet of sulphur evaporates with great rapidity, and leaves a thin layer of gutta percha, which acts as a preservative against the influence of air. On account of this M. Vogel has employed this solution to cover wounds caused by a cutting instrument. The carburet of sulphur in evaporating produces a sensation of cold in the skin, which acts as an antiphlogistic, and a re-union of the margins of the wound is readily effected. The sulphuret of carbon should be quite pure and free from all traces of sulphuretted hydrogen. This may be effected by treating it with litharge or carbonate of lead. He has also employed this solution for covering the surfaces of fruit which it is wished to preserve in a collection of natural history. Up to the present time a solution of wax has been employed for this purpose, but there is a great difficulty in removing the wax from the fruit without tearing the surface. The solution of gutta percha, which completely prevents the fruit from drying, has also the advantage of being easily removed by means of hot water. The solution offers also a great advantage for paintings and drawings, for it possesses the property of fixing in the paper, pencil, chalk, or charcoal drawings in such a manner that it is impossible to injure them by friction.—*Medical Times.*

NEW METHOD OF PREPARING CHLOROFORM.

The following method of preparing chloroform is recommended by Professor Böttcher:—Equal parts of chloride of lime and acetate of soda are distilled to dryness in an iron retort. But little chloroform is obtained in the first distillation, but a large quantity of dilute acetone, which is mixed with chloride of lime and submitted to a second distillation. But the whole of the acetone is not decomposed in this operation, and it is consequently necessary to mix the product with more chloride of lime, and again distil. The product is rectified over caustic lime. This method is said to effect a great saving.—*Polytech. Notizen Blatte*, No 1.

LIQUID INDIA-RUBBER AS STICKING PLASTER.

[It will be remembered that Mr. Douglas Fox, of Derby, drew attention to the utility of the liquid India-rubber at the last anniversary meeting of the Provincial Medical and Surgical Association, a notice of which subsequently appeared in the Journal. Mr. Fox has since communicated the following particulars to the *Lancet*.]

If liquid India-rubber, spread upon calico, or other material, by a stiff brush, or by a knife, be used as adhesive plaster, it will be found to answer far better, in almost every case, than any other adhesive material, as it sticks firmly, is pliant, produces no irritation to the skin, and will bear lotions, or washing over it. It is also most valuable in cases where the skin requires a soft plaster of an unirritating nature for its defence, as in old persons, or others long confined to bed. In such cases, it is better to use either soft leather or the vulcanized India-rubber, made in thin sheets; the latter, from its elasticity, is often the best, as it stretches with the skin on every movement of the body. To many kinds of wounds, from operations or otherwise, strips of thin vulcanized India-rubber, spread with the liquid, will be found invaluable as elastic adhesive plasters, as they become firmly attached to the skin, and give way to all its movements. But should any wounded part require a portion of the plaster to be non-elastic, as in the case of operation for hare-lip, &c., then, in order to secure such part from being stretched, a short piece of calico, about an inch in length, should be stuck upon the middle of the elastic plaster, by which means that portion would become stationary.

If a circular piece of thin vulcanized India-rubber, about two inches in diameter, be spread with the liquid, and applied on the abdomen of an infant having umbilical hernia, and a common bandage, such as is generally used for infants, be passed lightly round the body, the protrusion will be instantly checked; and if the same plaster be again spread with the liquid and re-applied, when it comes off from time to time, no trouble will be experienced by the infant. It is not necessary to use any pad or compress.

The liquid, which is like thick treacle, and the vulcanised India-rubber, may be procured in most large towns. (They are manufactured in Manchester, by Charles Mackintosh and Co.) In most cases, the thin sheet of the vulcanized India-rubber, or that sold as No, 50, will be the most suitable; in other cases, the thicker, or the No. 36, will be advisable.

The most convenient method of carrying the liquid is in one of the small, compressible bottles, used by painters, holding about an ounce, so that on removing the screw-cap, any required quantity can be squeezed out.

The above statement will give a general idea of the subject; the materials may of course be used in a vast variety of forms.—*Lancet*, Feb. 19.

MINIMUM FATAL DOSE OF ARSENIC.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In reference to Dr. Castle's case of poisoning by arsenic, I feel exceedingly obliged to you for reminding me of the case reported by Dr. Letheby, of which I now remember having taken a note, but had overlooked it in the multitude of (as yet) unarranged facts which are daily crowding upon me.

I readily admit that a well-authenticated case of poisoning, by two grains and a half of arsenic, taken

at one dose, should have its weight in guiding our opinion, on such a case as the one under discussion; still, after placing every sentiment of deference in the scale, I cannot bring my mind to think that it ought to be put on record as a case of poisoning by two grains of arsenic, taken in divided doses for three or four days. I really think that future toxicologists, finding such a case on record, resting upon "*imperfect evidence*," as to the dose, and not without suspicion of other poisonous substances having been taken, would say that it weighs nothing. The detection of *traces* of arsenic in the viscera is certainly no absolute proof of the cause of death, considering the extreme delicacy of our tests; for it cannot be doubted that such traces might be found in the body of a patient taking arsenic medicinally, and dying accidentally. On the other hand, assuming that arsenic destroyed life, the bare possibility of the deceased woman having taken *more* of the poison than appeared in evidence (for she might have been taking it for weeks,) appears to me to destroy the value of the case, considered as a *fact* in toxicology, although I confess that the publication of such a case, notwithstanding all its doubtful points, ought to awaken the utmost vigilance, as well as quicken our zeal, in the pursuit of an inquiry so fraught with interest as the action of minute doses of arsenic on the human frame.

Allow me to add that I feel honoured by the impatience expressed by Dr. Castle for the conclusion of my inquiries, he may be assured there will be no unnecessary delay on my part. I still wait in the hope of further communications from members, from *hundreds* of whom I have as yet received no reply.

I am, Sir,

Your obedient servant,

THOMAS HUNT.

Herne Bay, July 26, 1848.

PETROLEUM IN ASIATIC CHOLERA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

At the present time, when many persons are anticipating with fearful anxiety the arrival of the cholera on our shores, any information which may throw light upon the true nature of the malady, or the introduction of any new agent which may possess remedial powers against it, deserves our attention. Petroleum, it appears, from the report of Dr. Andreyoski, has been found to possess very valuable properties as a remedy in this justly dreaded disease; and I find from a letter in the last number of the Journal, Dr. Tunstall, of Bath, brought it under the notice of Sir Charles Napier, two years since, with the same view. Our knowledge of the *modus operandi* of many medicinal agents is very limited and uncertain, but I always feel a greater degree of confidence in prescribing when I imagine I have something like a definite notion of the action of the medicine I am about to use. My object in making the foregoing remarks, is to call the attention of Dr. Turnstall to what appears to me an inconsistency in his views of the action of petroleum. He says it has been demonstrated by Dr. John Davy and others, "*that the respired air of cholera patients contains a much smaller proportion of carbon than is sufficient for the proper purification of the blood;*" and then proceeds to say, "*Now, in the petroleum, we have a medicine that acts primarily as a powerful stimulant, secondarily by supplying the system with its due proportion of carbon for excretion; while its effects being produced by means of the absorbent system it acts beneficially as an antiseptic, preserving the frame from the rapidly fatal effects of this horrible disease by evolving carbonic acid from the lungs.*" I must confess that I cannot understand this secondary action, as explained by Dr. Tunstall. We are first told that the blood is not sufficiently purified of its carbon; and then we are recommended to use an agent which will supply the system with its due proportion of carbon for excretion, &c. Surely this is not scientific treatment. If the system is already overcharged with any element, we cannot expect to relieve it by administering more of the same, though I am aware that the doctrine of "*similia similibus curantur*" is professed to be held by some people.

I shall be glad to find that further experience confirms the value of petroleum as a remedy in cholera, anticipated by Dr. Tunstall; but if you think with me, that there is a little ambiguity in his idea of its mode of action, you will oblige me by inserting this letter in the Journal at your earliest convenience.

I have the honour to be,

Your obliged servant,

GEORGE SOULBY.

Dover, July 19, 1848.

INFLUENCE OF INSUFFICIENT FOOD ON THE GROWTH OF THE FŒTUS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In the last number of the Journal you have inserted, (copied from the *Lancet*,) a case occurring to Dr. Frentruss, from which he infers that the fœtus may be *so reduced in size by starvation of the mother*, as to be born alive at the full period of gestation through a distorted pelvis; you will perhaps not consider the space misapplied in giving publicity to the following *controverting fact*.

M. R., reduced by the intemperance of herself and husband from easy circumstances to almost the lowest point of destitution, having barely sevenpence per diem for the support of the whole family, comprising herself, husband, and three young children, was delivered by me after a quick easy labour, in the month of August, 1843, of a *fine stout healthy boy*. She was then lying on the bare floor, covered only by a ragged quilt, in an apartment without one article of furniture, without the meanest necessaries, and in one corner of which, were crouched her three, absolutely naked children. No improvement whatever occurred in her circumstances, for they were *too proud* to apply to the parish, and their habits seemed to have disgusted every friend,—even their relatives had no compassion for them. I was, therefore, much grieved to be again

called to attend in about fourteen months from the former labour, during the whole of which time she *suckled the first child*. The labour was again easy and quickly accomplished, and the child as well-developed and healthy as under the most favourable circumstances. The first child had become emaciated and sickly by the poverty of its *only food*, its mother's milk.

I leave the comparison of these cases, and the result, in the hands of your readers.

And remain faithfully yours,

EVAN EVANS.

Bath, August 3, 1848.

MEDICAL LEGISLATION.

MEETING AT MANCHESTER.

At a meeting of the members of the Royal College of Surgeons of England resident in Manchester and its neighbourhood, convened by public advertisement, and held at the Town Hall, on Tuesday, July 11th, 1848, W. B. Beever, Esq., in the chair,

It was proposed by Daniel Noble, Esq., and seconded by Dr. Rayner, of Stockport, and resolved:—

That this meeting hereby records its decided opposition to any measure of legislation affecting the constitution of the medical profession, which may ratify the retrospective act of injustice involved in the provisions of the charter recently granted to the College of Surgeons, at the instance of the Council.

It was proposed by James Bower Harrison, Esq., and seconded by D. Bowman, Esq., and resolved:—

That the invidious proceedings of the Council in regard to the fellowship, have deprived it of the value and consideration which, under other circumstances, it would have possessed, and that in the opinion of this meeting it would be derogatory on the part of those who were members of the College anterior to the date of the charter of 1843, to procure admission to the fellowship by re-examination and further pecuniary payment as at present proposed.

It was proposed by Thos. Dorrington, Esq., and seconded by G. Southam, Esq.:—

That this Meeting conceives the Colleges of Physicians and Surgeons once placed in just and harmonious relation with their respective members, to be amply sufficient for all the requirements of medical science, and that the institution of a third and subordinate College of General Practitioners would, under such circumstances, introduce needless complication, and be prejudicial to the best interests of the profession.

It was proposed by R. H. M'Keand, Esq., and seconded by G. Southam, Esq.:—

That a Committee be appointed, consisting of the following gentlemen, with power to add to their number, to carry out the above resolutions:—Mr. Beever, Dr. Rayner, Messrs. Noble, M'Keand, Bower, Harrison, Southam, Yorke, Wood, Leah, and Bowring.

It was proposed by A. Featherstonehaugh, Esq., of Bolton, seconded by J. Leah, Esq., of Gee Cross:—

That the Committee be requested to publish the proceedings of this day in such a manner as they shall deem most advisable.

Proposed by John Windsor, Esq., and seconded by T. Dorrington, Esq.:—

That the best thanks of this meeting be given to his Worship the Mayor, for his kindness in allowing the use of the Town Hall, for the purposes of this meeting.

(Signed) W. BEEVER, Chairman.

JOHN WINDSOR, Esq., in the Chair.

Proposed by R. T. Hunt, Esq., seconded by T. Fawcett, Esq., Oldham:—

That the best thanks of this meeting be given to W. W. Beever, Esq., for his impartial conduct in the chair.

(Signed) JOHN WINDSOR, Chairman.

GLOUCESTERSHIRE MEDICAL & SURGICAL ASSOCIATION.

MEDICAL REFORM.

At a special general meeting of the members of the Gloucestershire Medical and Surgical Association, held at Cheltenham, on the 20th day of July, 1848, "To take into consideration the proposals for a measure of medical reform, lately published, as resulting from a conference of parties representing the metropolitan corporations and the general practitioners, and intended as the basis of an Act of Parliament for the regulation of the profession," Thomas Wright, Esq., M.D., President, in the chair, the following resolutions were carried unanimously:—

1. That the Charter granted to the College of Surgeons, in 1843, forms an insurmountable obstacle in the path of medical legislation, and that no attempt to adjust, by Act of Parliament, the difficulties of this subject, can be successful or satisfactory until the injustice perpetrated by that obnoxious measure be done away with.

2. That the Colleges of Physicians and Surgeons, if rightly organized, are quite sufficient for the requirements of the profession in this country, and that the proposed creation of a new corporation for the enrolment of the general practitioners is uncalled for by any necessity, and that such new institution would be alike injurious to the interests of the profession and the public.

3. That the parties who have undertaken to appear on the part of the general practitioners in the conferences which have led to the proposal of a new corporation, have no title whatever to be considered as representing the views and opinions of that great body of the profession.

4. That this Association pledges itself to oppose, by all means in its power, the adoption of any legislative measures which may tend to perpetuate the injustice inflicted upon the members of the College of Surgeons by the Charter of 1843.

5. That a memorial be forwarded to the Secretary of State, and a petition presented to the House of Commons, embodying the foregoing resolutions; and that a Committee be appointed for the purpose of drawing up such memorial and petition, and giving publicity to the proceedings of the meeting.

J. W. WILTON, F.R.C.S., Hon. Sec.

THE APPEARANCES ON OPENING THE BODY OF SIR THOMAS LYTTELTON.

16th Sept., 1751.

On opening the abdomen or lower belly we found all the parts perfectly sound.

In the breast or thorax the lungs appear'd of a livid colour, and through their whole substance were allmost fill'd wth small schirrous tubercles, interspers'd wth. purulent matter but quite free from any adhesion to the containing parts. In the left cavity we found more than a pint of a yellowish brown serous fluid. The great artery just above the heart & below it down to the bottom of the abdomen, was distended to an immense degree, & just at the heart this sac or cyst contain'd a large polypus, that weigh'd 2 ounces, of a hard, fleshy, and curdly substance. This cyst adher'd firmly to the vertebre of the spina, at the curvature of the aorta, or large artery. The spine was considerably distorted & bent to the right side at the place of this adhesion.

The bones of the cranium or skull were join'd together so close, that they appear'd as one continued bone.

The membranes of the brain, & the brain itself through its whole substance, appear'd perfectly sound.

The 2 lateral ventricles of the brain were very full of a clear limpid fluid.

We found the eye that he had most complain'd of perfectly sound and well.

J. Harvey.
Wm. Grosvenor.
Thos. Saunders.
Read Shaw.

Medical Intelligence.

APPOINTMENTS.

Dr. Babington and Dr. Jeaffreson have been appointed Consulting Physicians, Mr. Aston Key, Consulting Surgeon, and Drs. Peacock, Bentley, and Allan Williams, Physicians, to the City of London Hospital for Diseases of the Chest.

James Moncrieff Arnott, Esq., F.R.C.S., Surgeon to the Middlesex Hospital, has been appointed Professor of Surgery at University College, London, and one of the Surgeons of University College Hospital.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, July 21st:—W. N. Price; R. S. Harvey; T. Leeson; A. B. Jones; C. H. Gamble; E. E. Phippen; J. W. Harper; J. W. Trotter; O. H. Jennings; G. S. Knight; J. Sturdy; and T. Lunbery.

Monday, July 24th:—G. W. Peake; D. D. Murphy; G. F. Trimnell; E. J. Lazarus; H. Eales; G. E. Driver; C. C. Piper; R. C. Smyth; and T. B. Knott.

Friday, July 28th:—F. Deane; J. P. Smith; W. Robinson; H. Coleman; D. Thomas; W. C. Satchell; T. Alcock; E. Sewell; S. T. Gwynn; and M. Gosling.

Friday, August 4th:—C. Underhill; E. Horuer; J. Hendley; E. Andrews; R. O. Clark; J. King; and H. Bowe.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, July 20th:—Charles Walter Poulton, Cricklade; Henry Tizard, Weymouth; Charles Crowdy, St. John's, Newfoundland.

Thursday, July 27th:—Joseph Drew, St. Austle, Cornwall; William Davis, St. George's Town, Salop; Joseph George Thompson, St. Mabyn, Cornwall; Charles Smith, Weyhill; Louis Truefitt, Hyde Park.

OBITUARY.

Died, August 25th, at Speenhamland, near Newbury, Berks, aged 64, John Mort Bunny, M.D.

August 26th, at Fiddington House, near Devizes, aged 29, John Willett, M.D.

Lately, aged 61, Sir Joseph De Courey Laffan, Bart., K.H., M.D., and L.L.D., formerly Physician to the Forces in the Peninsular War, and to his late Royal Highness, the Duke of Kent.

BOOKS RECEIVED.

Outlines of Lectures on the Nature, Causes, and Treatment of Insanity. By Sir Alexander Morison, M.D., Fellow of the Royal College of Physicians, London, &c. &c. Edited by his son, Thomas Coutts Morison, late Resident Medical Officer of the Norfolk County Lunatic Asylum. Fourth Edition, with Plates, and much enlarged. London: Longman. 1848. 8vo. pp. 481.

A Course of Lectures on Dental Physiology and Surgery, delivered at the Middlesex Hospital School of Medicine. By John Tomes, Surgeon-Dentist to the Middlesex Hospital. London: Parker. 1848. 8vo. pp. 397.

Scriptural Authority, for the Mitigation of the Pains of Labour, by Chloroform and other Anæsthetic Agents. By Protheroe Smith, M.D., Member of the Royal College of Physicians, Physician to the Hospital for Women, &c. &c. London: Highley. 1848. 8vo. pp. 52.

The Eighth Annual Report of the Registrar-General of Births, Deaths, and Marriages in England. London: 1848. Folio, pp. 144 and 330.

Return of the Mortality in 117 Districts of England, for the Quarter ending June 30th, 1848.

The Clinical Repertory.

The Student's Clinical Memorandum Book.

TO CORRESPONDENTS.

Communications have been received from Dr. Kingdon; C. A.; Mr. Allan; Mr. G. Bowring; Mr. E. Twining; Dr. Toogood; Dr. J. M. Duncan; Mr. T. Hunt; Dr. Heaton; Mr. E. Evans; Mr. G. King; Mr. Law.

A Subscriber:—We believe not, but we would recommend our correspondent to make the inquiry from the authorities at the College and Hall.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNIVERSARY MEETING.

The Sixteenth Anniversary Meeting of the Association was held at Bath, on Wednesday, the 16th, and Thursday, the 17th, of August, 1848.

The following gentlemen recorded their names in the book kept for that purpose:—

James Tunstall, M.D., Bath; Thomas Nunneley, Esq., Leeds; J. P. Garlick, Esq., Leeds; E. Scholfield, M.D., Doncaster; C. Hastings, M.D., Worcester; G. Alton, Esq., Easton-in-Gordano; W. Colborne, Esq., Chippenham; F. Flower, Esq., Chilcompton; John Cardew, M.D., Bath; T. Hodgkin, M.D., London; W. J. Morgan, A.M., M.D., Bradford; G. W. Dyke, M.D., Corsham; J. S. Bartrum, Esq., Bath; James Stedman, Esq., Guildford; W. J. Wilson, Esq., Manchester; E. Hodges, M.D., Bath; W. J. Church, Esq., Bath; W. Conolly, M.D., Cheltenham; J. Conolly, M.D., Hanwell; J. Mackness, M.D., Hastings; R. F. Lindoe, M.D., Bath; R. G. Mayne, M.D., Leeds; W. Cantrell, Esq., Wirksworth; J. Heygate, M.D., Derby; Robert J. N. Streeten, M.D., Worcester; Thomas Martin, Esq., Reigate; John H. Fuge, Esq., Plymouth; Henry Terry, jun., Esq., Northampton; Clement Hawkins, Esq., Cheltenham; Charles Bayliffe, Esq., Chippenham; G. Soulby, M.D., Dover; Thos. Washbourne, Esq., Corsham; Thos. Paget, Esq., Leicester; G. Bottomley, Esq., Croydon; J. Hodgson, Esq., Birmingham; A. Adye, Esq., Bradford; T. L. Surrage, Esq., Clifton; G. W. Jotham, Esq., Kidderminster; W. Davies, M.D., Bath; J. J. Mitchell, Esq., Bath; C. Barham, M.D., Truro; G. Waldron, Esq., Bath; T. Barrett, Esq., Bath; C. J. F. Lord, Esq., Hampstead; J. G. Leete, Esq., Thrapston; Thomas Barter, Esq., Bath; J. Pearce, Esq., Bath; E. Blackmore, M.D., Bath; C. J. Edwards, Esq., Batheaston; Thomas Wheelan, M.D., Bath; H. F. A. Goodridge, M.B., Bath; R. Colthurst, M.D., Clifton; G. H. Hetling, Esq., Bristol; J. Colthurst, Esq., Clifton; E. Hunt, Esq., Bath; W. H. Brace, Esq., Bath; W. E. Gillett, Esq., Taunton; P. C. De la Garde, Esq., Exeter; J. C. S. Jennings, Esq., Lacock; T. Green, M.D., Bristol; J. B. Bartlett, Esq., Teignmouth; A. Paul, Esq., Torquay; C. Bailey, Esq., Chippenham; J. Toogood, M.D., Torquay; W. Kay, M.D., Clifton; G. Vicary, Esq., Warminster; E. Skeate, Esq., Bath; J. Prankerd, Esq., Langport; H Marrett, Esq., Bath; G. B. Wood, M.D., Philadelphia; W. F. FIRST GENERAL MEETING.

The Council having previously met, and arranged the order of the proceedings, the First General Meeting was held in the Assembly Rooms, on Wednesday afternoon. At the appointed hour (one o'clock) a large number of gentlemen had assembled, and the President, Dr. HEYGATE, having taken the chair, addressed the meeting as follows:—

Gentlemen,—I will not detain you one minute from the highly interesting and important subjects which will engross the attention of the present anniversary; but, gentlemen, I cannot quit this chair as your President, without expressing to you, and to the Association generally, the high gratification I have had in presiding over its general interests for one year; the more especially as I have discovered, during that year, a growing disposition on the part of every section of our profession, to unite hand and heart in cordially promoting what concerns the general good of the body politic. I have seen all petty jealousies gradually softening down. This is what was wanted, because it is notorious that the legislature has expressed a willingness to settle our differences, provided we can agree amongst ourselves. I have also the more pleasure in resigning this chair, knowing, as I do, that the gentleman who will be proposed for your consideration to day, will not only fill it with credit to himself, but with far more advantage to the Association than my feeble efforts have enabled me to do. Feeble, however, and inefficient as my efforts have been, I shall not cease, as long as life is spared to me, to feel a lively interest in this Society; not only on account of its vast importance to the provincial profession, but out of respect to its founder, my friend Dr. Hastings.

Dr. HASTINGS, of Worcester, said he had much pleasure in proposing George Norman, Esq., F.R.C.S., of Bath, as the President of the Association for the ensuing year. After the response which had been made to that nomination, he (Dr. Hastings) would not add another word, but would leave Dr. Woodforde, of Taunton, to explain the reason of the meeting being held in the ancient city of Bath.

Dr. WOODFORDE, of Taunton, said he had great pleasure in seconding the nomination of Mr. Norman, of Bath, as the President for this year, although he regretted that the meeting of the Association was not to take place at Taunton. Some of the members present might not be aware that in the year 1841, a purely local Association was formed at Taunton, which, in 1844, had united with the Provincial Medical and Surgical Association. In 1846, the Association was invited to hold its meeting at Taunton, but from previous arrangements it was impossible to accept the invitation, and the present year had accordingly been fixed upon. The death of the President-Elect, coupled with other circumstances, had compelled the Taunton Branch, to send a deputation to the Bath Branch, to request them to receive the Association in its place, which request had been most kindly acceded to; and while he felt sure that the interests of the Association would be promoted by its Anniversary being held at Bath instead of at Taunton, he would express the hope that as the advantages and objects of the Association became more generally known, in the part of the country from which he came, so its number of members would increase, and he would not despair of seeing the meeting held at Taunton in some future year. Dr. Woodforde concluded by seconding the nomination of Mr. Norman, as the President for the ensuing year.

Dr. HEYGATE said he need hardly put the resolution to the meeting. It was carried by acclamation, and George Norman, Esq., having been conducted to the chair, addressed the meeting as follows:—

PRESIDENT'S ADDRESS.

GENTLEMEN,—

On addressing you as the President of this Association for the coming year, allow me to express the high sense I entertain of the honour you have conferred on me, and to thank you for having placed me in that situation. The gratification, however, which I feel in this compliment is deeply mixed with a regret,—one in which I am convinced you will all participate,—for the unforseen circumstances which occasioned the removal of the Anniversary Meeting from Taunton to this place, and with a heart-felt sorrow for the melancholy death of Dr. Macmullen, your late President elect.

It is quite unnecessary for me, gentlemen, at this, the sixteenth Anniversary Meeting, to explain the principles of the Association, or the objects for which it was founded; these have been so often, so ably demonstrated, and so efficiently advocated in the Addresses of former Presidents, more particularly those of the first years of its existence, that it would be presumption in me so to occupy your time. It will be more appropriate for me, in the observations I have the honour to make to you, to speak of the present state, and to refer to some of the objects which have been attained by the Association.

In the report of the first Anniversary, in 1839, it is stated that 313 was the number of its members; each year since then has gradually added to that number, and we now report 1795 to be the present amount of members. This fact, gentlemen, evinces how fully the advantages of such an Association have been appreciated, and how zealously its objects have been carried out by the great body of medical men in the provinces.

The Annual Meetings of this Society have exhibited the true character of the medical profession, by showing how large a number assemble without any private object,—without the smallest chance of advancing their individual interests,—with the certainty of pecuniary loss,—for the sole purposes of improving their professional knowledge, and of promoting the inducements to intellectual and honourable conduct in their services to the public, and their transactions with each other. The medical practitioner, in the circle of his daily avocations, has little opportunity, and possesses few means of associating himself with the pursuits of general society; he is only sought for by others in their misfortunes; he only sees them in their misery; and as it is a character of the human mind to forget calamity when its urgency has passed by, it often happens that the medical man is, to a certain degree, forgotten, if he have not other claims on the notice of his vicinity.

It is true that by a long and conscientious discharge of professional duties, many individuals have gained a high position, and an honourable estimation in their own localities; but as a body, the medical profession is less known, its difficulties, its anxieties, its labours, and the amount of its reward less understood, than any one of the other professions,—nay, than almost any class of labourers in the field of industry and of general utility. But these, our Annual Meetings, by giving to us unity, strength, and importance, have made the general public better acquainted with the character of our profession; and I trust the time may arrive, when both the public and the legislature will better appreciate the opinion of our profession on medico-legal subjects, and all others connected with the social and sanitary condition of the people,—subjects on which medical men, from their peculiar education and avocations, have the means of forming a correct, because a practical, judgment.

The amount, gentlemen, which this Association has contributed to the advancement of medical science, may be estimated by the volumes of its Transactions,—by the industry and talent bestowed on many of the papers, particularly in the various Retrospective Addresses, which have given origin to two valuable works by members of this Association, the "Retrospect of Medicine," by Mr. Braithwaite, and the "Half-Yearly Abstract of the Medical Sciences," by Dr. Ranking. These works have rendered the reading of a Retrospective Address at these meetings unnecessary, are easy of access, and are now held in deservedly high estimation by all members of the profession. I trust, gentlemen, the volumes of your Transactions may continue to be nourished by the contributions of all those members who possess the opportunity and leisure.

The diffusion of medical information amongst the members has been much promoted by the publication of our periodical Journal every alternate week, which affords an easy mode of recording and communicating, throughout the Association, any circumstance or case of unusual interest; and, conducted as it now is, by its talented Editors, on the plan recommended by the Committee, it not only answers the expectations of the Association, but forms a valuable addition to the medical press.

The Association has also derived considerable advantage from the formation of Branches in various localities, which carry out the objects of the Association in more frequent meetings, by which unity and mutual good feelings are promoted amongst the members of the Branch, and a spirit of inquiry and investigation kept up by which materials are collected and forwarded to the Parent Society for publication in the Journal. One other mode of advancing medical science, and of giving credit to the Society, has been adopted by the Council, and will come into operation for the first time at the present meeting—that of offering a prize for the best essay on a subject proposed by the Council,—a plan which has been adopted by the Royal College of Surgeons, and by other associations, and which it is hoped may prove advantageous to this.

There is, Gentlemen, one other object of this Association, intended for the advantage of its members, which has been in some degree attained, but requires yet to be perfected—the formation of an adequate Benevolent Fund, for the relief of such of our members as from illness or from unavoidable adverse circumstances may have been placed in temporary difficulty, for more permanent assistance to one entirely disabled, or to the widow and orphans who may have been prematurely deprived of the support of a professional income. Even an approach to the maturity of such an object must be of slow growth; for in so large a number of persons as the members of our profession, adversity must be the lot of many, and of some who have struggled hard to avert its evils. The amount of relief required under such circumstances must be considerable, yet the means of supplying it can only be slowly accumulated. The expenses attending the proper performance of the duties of a medical man, the degree of respectability in the appearance and mode of life of his family, and in many instances the inadequacy of his remuneration, make it difficult for him to do much for the assistance of his brethren, and present serious impediments to the formation of an adequate fund. Much, however, has been done, as will be detailed by the Report, which may, I hope, shew a progressive improvement.

Miseris succurrere disco, is one of the mottos of our profession, and while we render our services to the general community, and afford our assistance gratuitously to the sufferer destitute of means to a greater extent than any other class of persons who have to support themselves by their labour, surely we shall not pass by our brethren either in their maladies, or in their adversity. *Nihil homini carius quam sui cuique libari*, and in this instance the children of misfortune should be our own. I trust, Gentlemen, that every member will consider the Benevolent Fund to be an integral part of the Society's objects, and will render his graduated assistance to its support.

Many important works on medicine and surgery have been published, Gentlemen, in the past year, and much valuable information afforded by the periodicals, which, to notice ever so briefly, would exceed the limits of this address.

The inhalation of æther and subsequently of chloroform, for the mitigation of suffering under the painful operations of surgery, has in the past year exerted in the public mind and in the profession an interest, not more than commensurate with the value of the discovery, if the safety of its application be established. From facts derived from various authorities, it appears that, independent of the saving of pain, another important advantage has been gained by the smaller proportion of deaths after capital operations where chloroform has been inhaled, compared with the results of such cases before that practice was employed. The analysis of the reports obtained by Dr. Simpson, shews a saving of life of eleven per-cent. above the lowest mortality of those who have undergone amputation unætherized, and of thirteen per-cent. above the success of British hospital practice in eight years previous to its introduction,—a result which may fairly be attributed to the diminished shock to the constitution in an operation without pain. It is, however, true, that some deaths have occurred from its use,—I believe five have been recorded,—a sufficient reason for not coming to a hasty decision on the subject. In all the most important and painful operations there is reason to believe the practice will be adopted and will prove highly valuable. In all such operations the mortality must be great, and the risk arising from inhalation, which, if properly conducted, with due regard to all circumstances, is not considerable, must be taken with the rest; but I am not disposed to assent to the use of chloroform in minor operations, not usually attended by danger to life.

The subject of Medical Reform has been considered by this Association from the time of its first formation, to be one of great interest to our profession; and by advice, and by active co-operation, the Council has on various occasions endeavoured to forward the progress of that measure to a final settlement by the Legislature. It is to be regretted that the object cannot be obtained in this Session of Parliament, and that medical men are to remain in the same unsatisfactory state, without any adequate legal protection, and with a very ill-defined title to the position they hold. There is, however, reason to hope, that the conferences which have taken place between the different departments of the profession, in which a committee of this Association has taken part, may be the means of framing a measure against the next Session, which may meet the wants of the profession and obtain the sanction of Parliament. If I might venture an opinion on the subject, I would suggest that those points which are most essential for the protection of the profession, on which all can agree, should be brought before Parliament without endeavouring to include every desirable object, lest by endeavouring to gain minor advantages, we lose the opportunity of obtaining those which are essential, and by raising subjects for difference of opinion, we bring on ourselves a censure which has been cast on us, either that we do not rightly understand our own wants, or that we are too much divided amongst ourselves to agree in them.

The situation of the medical officers of the Unions, and the inadequate scale of their remuneration, will form an especial subject for the consideration of the Association, and will no doubt receive that attention its importance merits. I will only say that I hope, by the combined movement of the Union Surgeons, and the better disposition evinced by the authorities, justice, though tardy, may ultimately be secured to that class of practitioners.

In allusion, Gentlemen, to the events of the last year, I should not do justice to the feelings of the Association, or to my own, were I to omit to pay some brief tribute of respect to the memory of those who have departed this life within the period. The number of our members, and the still larger number of those who have not belonged to our Association, who have been removed from among us, has been lamentably great. The report just now published by the Registrar-General, gives a considerable augmentation on the usual average of deaths in the past year, and our profession has partaken of the general mortality; but in Ireland a fearful number, and in our own island many valuable lives have been sacrificed to malignant fever. The loss of so many valuable men, with the distress of their families, is greatly to be lamented, but it is not the character of our profession to be deterred from pursuing the path of duty by its dangers.

Amongst those of our Association, the name of one of our Vice-Presidents, Dr. Holme, of Manchester, stands pre-eminent—one of the first and most indefatigable promoters of this Association. He was never absent from our meetings, where his talents graced, and his judgment advanced, every object of our Society. His memory will ever be preserved in the annals of this Association. Dr. Kendrick, of Warrington, a physician of literary, as well as medical celebrity; and Mr. Kenrick Watson, of Stourport, were two of the earliest members of our Association. Mr. Jubb, the late Senior Surgeon of the Halifax Infirmary; Dr. Hardwick of Kensington; Mr. Coates, a surgeon of eminence, for many years belonging to the Salisbury Infirmary; Mr. Barlow of Blackburn; and Mr. John Walker, of Manchester, have died in the past year, the last two of fever taken in performance of their duties. In this neighbourhood, we have lost Dr. Bompas, President the year before last of the Bath and Bristol Branch; Dr. Riley, of Clifton, a Lecturer in the Bristol School of Medicine; and our friend, Dr. Macmullen, of Taunton, who at this hour would be addressing you, but for the attack of that direful malady under which he so rapidly sank.

Of those who were not members of our Association, the name of Liston requires our particular notice. The high position he held as a teacher and an operator, renders his loss, at a comparatively early age, a source of regret. He introduced into English surgery, a dexterity and celerity of operating which would somewhat have surprised the slow and cautious surgeons of the last age. By varying the plan as well as the mode of operating in some of the principle operations, he has rendered considerable service to that department of our art. Nearly at the same time, and at about the same age, a surgeon of no less eminence at Berlin, Professor Dieffenbach, died suddenly. He also introduced improvements in the department of

surgery by his novel and successful operations for various deformities.

I turn now, Gentlemen, from this sad subject to one of more pleasure, to express the gratification of my colleagues and myself by this your visit to our city. History is too familiar to all for it to be necessary to say ought of ancient, and your own observations will soon make you acquainted with modern Bath. The only topic to which I would carry your attention in the past, is that of a few of the distinguished men in our profession who have flourished here. We have had a Charlton, a Haygarth, and during the latter part of his life, a Currie,—names well known; Dr. Falconer, a man of great classic, as well as professional, knowledge, the author of a treatise on Bath waters; and Dr. Harington, an elegant classical scholar, a mathematician, an able physician, and the composer of some esteemed musical compositions of the higher class and others, combining perfect harmony with polished wit.

Amongst the names of those who have devoted their lives to the improvement, as well as the practice of our art, the name of Parry will ever hold a conspicuous place,—the friend and fellow-student of Jenner; the author of a work on "Syncope Anginosa," in 1799, an early step in our knowledge of the various lesions of the heart; on the "Nature of the Arterial Pulse, with Experiments on the Arteries;" and of "Elements of Pathology," in which are advanced doctrines derived from his acute and accurate observation, many of which have become established principles with all the enlightened of our profession. If I have dwelt too long on my notice of the late Dr. Parry, my excuse must be, the almost filial regard I have for the memory of one from whom I gained more valuable instruction in my profession than from any other single source, and who gave to my early efforts his powerful support in ascending that difficult and slippery path which the aspirant in our profession has to encounter in his first attempts. The name of another cotemporary and friend, one well known to this Association, is that of Dr. Barlow, the able assistant of our founder, Dr. Hastings, in the formation of this Society, and the zealous promoter of its interests; his name will long be remembered where his professional energies were exerted to a degree almost without parallel amongst the sick poor of this city. To that name I would add Dr. Crawford, though not a member of our Association; he practised extensively here for forty years, enjoying the estimation and regard of his brethren, his patients, and his friends. Of the names of our surgeons, though many, I need only mention that of Mr. Tudor, one of our Association, and that of Mr. James Norman, whose exertions founded the Casualty Hospital in 1788; of him I dare say no more than to express the reverence and regard entertained for his memory by his son.

The first object of interest connected with our profession in this city, Gentlemen, is the establishment for the use of the Bath waters—the Pump Rooms and the Baths. These were built out of the funds entrusted to the Corporation, with a degree of elegance and accommodation not to be surpassed, I may almost say equalled, by any thermal establishment in Europe. The history, the properties, and the analyses of these Waters, have been amply detailed by Falconer, Sir George Gibbes, Barlow, and Doctors Spry and Wilkinson; to which may be added the experiments and the scientific observations of Professor Daubeny.

I may briefly state that the temperature of the water, as it rises from the bottom of the baths, is 117° at the hot bath, 115° at the King and Queen's bath, and 109° at the Cross bath, the temperature varying very little at any period. Dr. Daubeny ascertained that at the King's bath 28,339 cubic feet of water were thrown up in twenty-four hours, and with it gas, in the form of air-bubbles, to the amount of 222 cubic feet, in the same time. This gas he ascertained to be ninety-five parts of nitrogen, and five parts of oxygen. In an imperial quart of the water are about thirty grains of solid contents, and we may collect from the different analyses that these are,—

Sulphate of lime.....20 grains and a fraction.
Chloride of sodium.....5 grains and a half.
Carbonate of soda .....1 grain and 4-5ths
Silica .....7-10ths of a grain.
Proto-carbonate of iron..1-10th of a grain.

That so small a quantity of iron should produce as powerful an effect on the system as the larger doses usually prescribed in medicine, is one of the difficulties not easily solved in the consideration of these waters; another, is one stated by Dr. Wilkinson, that no chemist has hitherto effected their artificial production; their natural production is as yet matter of conjecture. Dr. Daubeny thinks they arise from volcanic processes, and that were it not for the abundant evolution of gasses at the springs, some volcanic eruption must have long since occurred. The depth from which the water arises has been pretty well ascertained a few years since by accident. The proprietor of premises, about one hundred and fifty yards from the baths, wishing to procure a very large quantity of water, sank a well sixty feet deep, and not finding a sufficient quantity, he commenced a process of boring, and continued it to the extent of 110 feet more, when, at the depth of 170 feet from the surface, there suddenly came on a flow of hot water, which rapidly reached the surface, and continued to run at the rate of 114 gallons in a minute. An immediate diminution of the quantity of water discharged into the baths took place, so that the King's bath, which usually filled in eleven hours, required sixteen, and there was also a slight diminution in the temperature; that of the water at the new opening was only 99°, from the admixture of cold water in the well; but the analysis of the water by Dr. Edward Turner, and by Mr. Herepath, showed the water to be identical with the Bath water. By the persevering exertions and skill of Mr. Armstrong, the civil engineer, of Bristol, this calamity was effectually remedied. As soon as he had succeeded in stopping with cement the boring hole which had been made, the full quantity of water was restored to the baths, of as high a temperature as before the accident.

The internal use of the Bath water is beneficial in cases of impaired power in the stomach and digestive organs, in all cases where chalybeate medicines are indicated, and as a tonic in convalescence from

various maladies. The external application by means of the baths and the douche is beneficial in cases of palsy, by stimulating the branches of the nerves after the primary disease in the nervous centres has been in some degree repaired, and by giving additional power to the muscles. It is also useful in restoring the power of limbs impaired by gout and rheumatism, and in reducing the obstinate inflammatory tendency in the chronic forms of the latter complaint. In no disease is the Bath water more decidedly advantageous than in the peculiar form of palsy arising from the poison of lead, denominated painters' colic.

The mode of employing the Bath waters varies according to the indications of cure in each complaint. At a low temperature they may be used like the Buxton baths, as modified cold bathing: at 92°, 94°.96°, as tepid bathing: at 98°.100°, and even at 110°, they are used for the purpose of reducing chronic inflammation, when the patient remains in the bath for twenty, or even thirty minutes, is then removed to a bed between blankets, remaining there for an hour or more, and this repeated three times a week. In this last mode of using the waters and in the very small quantity of iron contained in them, you will perceive that the modern phantasmata of Homœopathy and Hydropathy, have been substantially in use by the Bath waters for the last two hundred years.

The Bath General Hospital, situated in Union Street, is an establishment for the admission of patients from every part of the kingdom, whose cases are suited to the use of the Bath waters. It has existed for a long period, is governed by an Act of Parliament, and contains [?] beds. The medical officers of this establishment will be happy to shew the hospital and the baths, and to explain the mode by which patients are admitted.

The Bath United Hospital, which was opened in 1826, was formed by the union of two charities,—the Bath Casualty Hospital, and the Bath City Infirmary. This hospital contains 112 beds for the admission of in-patients, and out-patients are seen daily at the hospital by one physician and one surgeon, who attend for that purpose. This hospital is recognized by the Royal College of Surgeons, and by the Apothecaries' Company. There is a small museum belonging to the hospital, of anatomical and morbid preparations, the foundation of which was made by a collection of mine, transferred to the hospital on the union of the two charities; this has been added to by various specimens collected from the practice of the hospital, and enriched by many preparations of comparative anatomy, made by Mr. Gore, with the accuracy and discrimination to be expected from the translator of Blumenbach's "Manual of the Elements of Natural History," and of Carus's "Introduction to the Comparative Anatomy of Animals."

There are also in this city two Dispensaries, where patients receive advice and medicine, and an Eye Infirmary, established by Mr. Soden. There is a Literary Institution, containing a valuable library, a small geological collection, and a collection of Roman antiquities found in various parts of the old city.

Dr. Streeten then read the—

REPORT OF THE COUNCIL.

The Council of the Provincial Medical and Surgical Association, in presenting the Report of their proceedings during the past year, have first to explain to the members the reasons which have led to the change in the place of holding the meeting, as appointed at the last Anniversary. It is with regret that they have to assign as the main cause of this change the severe illness of the President-Elect, Dr. Macmullen, of Taunton,—an illness which not only precluded him from availing himself of his election to the President's chair, and from all hope of taking any share in the proceedings of the Anniversary, but has since terminated fatally. Under these circumstances, together with the loss which the Taunton Branch had sustained by the removal of their local Secretary, Mr. Higgins, from Taunton, the Branch Council were of opinion that it would be better for the interests of the Association that the Anniversary should not take place at Taunton on the present occasion; and as the Council of the Bath Branch kindly acceded to a request made by a deputation from Taunton, to receive the Association at Bath, the Council felt that they could not better consult the wishes of the members at large, than to avail themselves of the opportunity of once again holding an Annniversary in this celebrated city, and proposing to the meeting their esteemed Associate, Mr. Norman, of Bath, for election as President of the Association for the ensuing year.

The Council are happy to report the continued prosperity of the Association. The number of Members now on the books amount to 1795; but they have deeply to regret the decease of several of those who have long adorned the Association, and among them they have to mention, in addition to the President-Elect, one of their Vice-Presidents, Dr. Holme, of Manchester, whose firm attachment to the Association, and exertions in its behalf on all occasions, will for years be beneficially felt.

FINANCE.

The general statement of receipts and expenditure during the past year is as follows:—

	£.	s.	d.
Receipts	1436	19	5½
Balance due to Treasurer	22	10	4½
Expenditure	1396	8	8½
Balance in hand	18	0	4½

The Treasurer will lay before the Meeting a detailed statement of the particulars of the accounts; but the Council would again urge upon the Members the necessity which must always exist for the regular payment of the subscriptions, and without which it is impossible that the concerns of such an institution as this can be carried on with advantage. They regret to have to state that several Members are yet considerably in arrear.

PUBLICATIONS.

The Council have to report, with reference to the publications of the Association, that it has been their endeavour, as far as was consistent with the funds at their disposal for the purpose, to carry out the recommendations of the Publications' Committee as adopted by the General

Meeting at Derby. Two subjects of inquiry have been especially recommended to the consideration of the Members, and the illustration which one of these subjects has already received in the pages of the *Journal* affords evidence of the value of this mode of eliciting information. The volume of *Transactions* for the present year has not yet been issued, partly because it has been thought desirable that the volume, or a portion of it, should be published immediately after the Anniversary Meeting, and partly because the Council are desirous of availing themselves in future, of the facilities afforded by the new Post-office arrangements, by which subjects of pressing interest may be immediately printed for the volume and issued directly through the Post-office to all the Members. Many collateral advantages will, it is further expected, attend this change; and the Council trust that, as soon as the Members have had experience of its working, they will find reason to be satisfied with the benefits resulting from it.

MEDICAL REFORM.

The Council, in referring to this subject, still in an unsettled state, though they would fain hope with better prospect of a satisfactory termination being ultimately obtained, would draw attention to the arrangements in progress with respect to two great classes of the profession. The results of the conferences held in London by the Corporate Bodies and the National Institute of Medicine, Surgery, and Midwifery, and by the Royal College of Physicians with a Deputation from the Council of this Association, are of considerable importance. On the promulgation of the proposed Charter of the Royal College of Physicians, as approved by the Joint Committee of Conference, the Council thought it their duty immediately to call the attention of the Physicians of England residing in the provinces to the bearing of this Charter on their rights and privileges; and subsequently, in a Memorial addressed to the College, the Council pressed upon that body the alterations which had been suggested to them in consequence. They have the gratification to announce that, with the exception of one point, all the recommendations of the Council will be found embodied in the draft of the new Charter now prepared for the College as the proposed Charter of the Royal College of Physicians of England. The Memorial of the Council, together with the reply of the College, has been published in the *Journal* and it is unnecessary, therefore, to refer to their proceedings further in this place.

On the publication of the Principles of Medical Legislation adopted by the Conference, the Council in like manner appealed to the Surgeons of England for the expression of their opinions on the subject, but did not receive in reply any communications which rendered it necessary for them to adopt measures on the subject, either with the Royal College of Surgeons, with the Joint Committee of Conference, or with Her Majesty's Government.

The Council, in common with the profession generally, had hoped, ere this, to have seen the question of Medical Reform settled, by the adoption of a comprehensive measure, founded upon those principles of equity and justice which the Association has for so long a period, and on such frequent occasions, declared to be the only just and equitable basis upon which such a measure can rest; but, believing that no measure will be found to be permanently satisfactory, and, consequently, desirable, which shall not recognize and enforce the views of the Provincial Medical and Surgical Association, consisting, as it does, of so large a number of all classes of the medical profession, it is to be earnestly hoped, that when any measure shall be introduced into Parliament, it will be of such character as will, by the adoption of sound and correct general principles, for ever allay the discontent of members of a profession whose time would be so much more profitably, both to themselves and the public, spent in scientific pursuits rather than in mutual recrimination and jealousy.

The rationale of medical education, and the amount of scientific and literary attainments which ought to be possessed by all those who shall, by the laws of the country, be declared qualified to practice physic, are sufficiently well understood and appreciated by the profession at large, so as to justify the declaration that the time has arrived for the Government to undertake the satisfactory settlement of the question.

The conferences which have been held will probably do good, and the information collected by the Committee of the House of Commons, now sitting, will, it is to be hoped, conduce to the introduction of a bill into the House, under such favourable auspices, and at such an early period of the next Session of Parliament, as shall insure its passing into a law.

The Council would, however, repeat what the Association has so often declared in the words unanimously adopted at the Annual Meeting at Sheffield, in 1845, that such bill will be found to "make it imperative upon all who may hereafter be admitted to practice in any of the recognized branches of the profession, that they shall, in their common entrance through one portal, undergo such an examination as shall exhibit a competent knowledge in all the departments of medical science. Further, that this examination shall be uniform in every part of the United Kingdom, and shall be the legal qualification for practice. The Council think that any measure which shall not recognize this uniformity of examination will be unsatisfactory to the profession, and detrimental to the best interests of the public."

POOR LAW.

The questions connected with Medical Relief under the Poor-Law were referred to a Committee appointed at the last General Meeting, by whom an Address to her Majesty's Secretary of State for the Home Department was then prepared. The members of this Committee have since been acting in conjunction with a general Committee of Poor-Law Medical Officers, by whom a mass of information on the subject has been collected, and brought under consideration of the Government authorities. Deputations from the General Committee have had interviews with Mr. Buller, the Chief Commissioner of the new Board, and with the Home Secretary and a Deputation from the Association was expressly appointed by the Council to accompany the General Committee in their interview with Sir George Grey. The Council are induced to believe that some more satisfactory arrangements than those at present existing

will result from these interviews, and that the information and details thus brought under the immediate notice of the Government will have the effect of placing the medical department of the relief of the sick poor upon a more equitable footing.

PUBLIC HEALTH.

The Committee appointed at the last Anniversary to watch the progress of any measure which might be introduced into Parliament for the improvement of the Public Health, have had their attention directed to the bill brought forward during the present Session by Lord Morpeth, but the Council have not hitherto received any report or suggestion from them on the subject.

BENEVOLENT FUND.

The Benevolent Fund has continued its quiet unostentatious course of mercy, and the past year has been marked by a considerable accession of donations and subscriptions, while the urgency and destitution of the cases relieved have been unusually great, and its timely succour proportionally appreciated. A detailed report will be presented at the meeting.

COUNCIL FUND.

The Council have to announce that two Essays "On the Cerebral Affections of Infancy," have been sent to compete for the prize of £50, offered by the Council of the Association last year. These Essays have been referred to the judges appointed at Derby, and their award will be communicated to the present Meeting. The Council have not hitherto offered any prize for the present year, but will proceed to select a subject for such purpose after the decision of the judges shall have been pronounced.

In bringing the present Report to a conclusion the Council cannot but congratulate the Meeting on the general prospects of the Association. The temporary difficulty in which an unlooked-for demand upon the general funds had involved their finances, is in course of removal; the publications are placed on a more satisfactory foundation; and the general objects—Medical Reform, Poor-Law Medical Relief, &c.—to which the attention of the Association has been from time to time directed, may be said to be at length holding out a prospect of settlement, on grounds as satisfactory, perhaps, as the complicated nature of human institutions admit of. The Benevolent Fund, also, they are happy to state, is in an improving condition. The Council will indulge the hope, therefore, that in each of the objects for which the Association has been constituted, an onward progress will continue to be made, and that succeeding Anniversaries will see the Association steadily carrying out its intentions, for the benefit and improvement of the profession, and forming more and more the rallying point of union for all classes of the profession, and especially for provincial practitioners, who, though separated by distance, have a community of interest and social feeling which such an institution as the Provincial Medical and Surgical Association is admirably calculated to promote and foster.

It was moved by Mr. Bottomley, of Croydon, and seconded by Dr. Davies of Bath, and carried unanimously, "That the Report of the Council now read be adopted and printed."

Dr. HASTINGS then read the Treasurer's Statement of Account, of which the following is an analysis:—

FINANCIAL STATEMENT.

Dr. HASTINGS then read the Treasurer's Statement of Accounts, of which the following is an analysis:—

Receipts.

Moved by Mr. Flower, of Chilcompton, seconded by Mr. George King, of Bath, and carried unanimously, "That Mr. Martin, of Reigate, and Mr. Garlick, of Leeds, be requested to act as Auditors of the Treasurer's Account, at this meeting."

PRIZE ESSAY.

Dr. STREETEN announced that the successful candidate for the Prize Essay was Dr. Duke, of 199, Great Brunswick Street, Dublin, and Dr. HASTINGS read the following report from the Committee appointed to adjudicate on the two essays which had been sent in:—

"We are of opinion, that both the Essays on the 'Cerebral Affections of Infancy' are of a very high order of merit; but we concur, without hesitation, in awarding the prize of £50 from the Council Fund, to the Essay bearing the motto 'Gradatim vincimus.'

"JAMES HEYGATE.
"A. ROBERTSON.

"Bath, August 16th, 1848."

Dr. Daniell, of Bath, said he had been requested to move what he was sure must be the feeling of all present, viz., "That the thanks of the Association be given to Dr. Heygate, for his services as President during the past year."

Mr. Paget, of Leicester, briefly seconded the resolution, which was carried by acclamation.

Dr. HEYGATE said, he had most cordially to return his thanks for the high compliment which had been paid him; first of all, in electing him as the President of the Association, and now for the thanks which had been awarded to him for

the services he had been enabled to render them in that capacity. He felt that, were it not for the kindness of friends, he should have discharged those duties but inefficiently; but, with their assistance, he had done what he could to promote the interests of the Association, and he begged again most cordially to acknowledge the vote of thanks which had been accorded to him.

It was then moved by Dr. Robertson, of Northampton, and seconded by Mr. Hodgson, of Birmingham, "That the thanks of this meeting be given to the President of the Council, Dr. Hastings, for his continued and zealous attention to the welfare of the Association."

The resolution having been put, and carried by acclamation,

Dr. HASTINGS said: To you, Dr. Robertson and Mr. Hodgson, I beg to return my best thanks for the very kind manner in which you have spoken of my services; and to you, gentlemen, one and all, I have cordially to tender my acknowledgments. I will only add, that I shall always feel a pleasure and pride in doing all within my power to promote the interests of your Association, and so to deserve your continued approbation.

Mr. Martin, of Evesham, moved, and Dr. Blackmore, of Bath, seconded the following resolution, which was carried unanimously:—

"That the thanks of this meeting be given to the Council of the past year, and that they be requested to continue their services with the following additional Members, and that they be empowered to add to their number:—

——— Skrimshire, M.D.,	Sudbury
Berrington Chevallier, M.D.,	Aspall
John Growse, Esq.,	Hadleigh
W. Worthington, Esq.,	Lowestoft
G. Sampson, Esq.,	Ipswich
John Kirkman, M.D.,	Melton
George Mayhew, Esq.,	Stradbroke
William Jeaffreson, Esq.,	Framlingham
Richard Jones, Esq.,	Woodbridge
Spencer Freeman, Esq.,	Stowmarket
Francis H. Woodforde, M.D.,	Taunton
Peter Martin, Esq.,	Reigate
Edward Hodges, M.D.,	Bath
Wm. Davies, M.D.,	Bath
James Stedman, Esq.,	Guildford
William John Church, Esq.,	Bath."

DEPUTATION FROM THE AMERICAN MEDICAL ASSOCIATION.

Dr. HASTINGS said, he begged to announce, and he did so with the greatest gratification, that they were favoured with the presence of a deputation from one of the largest bodies of the medical profession which existed on the other side of the Atlantic. He was sure it was the wish of all present that the union between this country and America should be more closely cemented; and that whether they were engaged in the advancement of science, or for the welfare of humanity, there should be a reciprocity of feeling between these two great countries. He would therefore read to the meeting the formal announcement of the fact which he had just made known:—

"The American Medical Association, constituted of delegates from the several States of the Union, recognizing the ties of a common brotherhood among medical men throughout the world, and desirous, by literary and personal intercourse, to strengthen the bonds of such alliance, alike as regards individuals and Societies designed like their own to advance the honour and usefulness of the profession, and entertaining these sentiments and views, especially towards the medical profession in their mother-country, at the annual session held in the city of Baltimore, on the 5th day of May, 1848, instructed the undersigned (its presiding officers and Secretaries) to accredit to the English Provincial Medical and Surgical Association, twelve of its members as delegates.

"In the exercise of this duty, we do hereby accredit as a delegate, our associate, George B. Wood, M.D., Professor of Materia Medica and Pharmacy, in the University of Pennsylvania.

"ALEX H. STEVENS, of New York, President.

"JOHN C. WARREN, of Massachusetts, } Vice
"SAMUEL JACKSON, of Pennsylvania, } Presidents.

"ALFRED STILLE, } Secretaries."
"HENRY J. BOWDITCH, }

Dr. Hastings continued—He thought he need hardly say one word to ensure the unanimous concurrence of the whole meeting on the resolution he was about to propose, after hearing the fact of Dr. Wood's coming among them—knowing also that he represented the whole medical profession of America—and standing as he did, in the highest rank in that profession, he (Dr. Hastings) was sure that every member of the Association would be anxious to show Dr. Wood the greatest possible respect. There were, in connection with the Association, various associates, who were styled honorary correspondents, residing in foreign countries, and he should have the pleasure of proposing that the name of Dr. Wood be added to that list. He would therefore at once move—

"That George B. Wood, M.D., Professor of Materia Medica and Pharmacy, in the University of Pennsylvania, one of the Physicians of the Pennsylvania Hospital, and President of the College of Physicians of Philadelphia, be appointed an Honorary Corresponding Member."

Dr. Heygate had very great pleasure in seconding the proposal of Dr. Hastings.

The President put the resolution, which was carried unanimously, all the members standing.

Dr. WOOD said he could not let the occasion pass without offering a few words, though he would not detain the meeting at any length. He would, however, say, how gratified he felt at being present at their meeting as the delegate of his medical brethren on the other side of the Atlantic, and how profoundly grateful he felt for the honour of being appointed one of the Associates. Perhaps he might be allowed to indulge in two or three observations in relation to his position there on the present occasion. He was travelling in

this country with personal views when he received his credentials from the General Medical Association of the United States, accrediting him as their delegate to the meeting of the Institutions of Great Britain; and although it was entirely out of his plan to be there at that time, yet he felt too much the importance of giving proper effect to this expression of the feeling of the medical profession in the United States to allow any personal considerations to weigh with him. The General Medical Association of the United States was, as its name explained, a society of the practitioners of America; it was established some three or four years since, for the purpose of conveying information, and promoting union among the members of the profession; an organization ensued, and this year the third meeting of medical men from every part of the United States, represented by delegates, had been held at Baltimore. The Association was not local in its objects, but might properly be considered as representing the medical profession of America; and his appointment as the delegate from such a body might, he thought, be taken as an evidence of the desire which existed for reciprocating kindly feelings between the members of the profession in this country and America. On such a subject it would be easy to enlarge, but as the time of the meeting was limited, he would do no more than again repeat his thanks for the honour which had been conferred upon him.

On the suggestion of Dr. Hastings, a reply to the document received from the American Society was ordered to be prepared, and Dr. Robertson and Dr. John Conolly, of Hanwell, were requested to prepare the reply, and submit the same to the evening meeting.

Dr. Wallis, of Bristol, proposed "That the thanks of this meeting be given to the Secretary, Dr. Streeten, for his services during the past year."

Dr. Lyon, of Manchester, seconded the proposition, which was carried unanimously.

Dr. Streeten, in returning thanks, said it was a source of the sincerest gratification to him to do all he could to promote the interests and to forward the views of the Association. That his exertions had met the approbation of the members was additionally gratifying to him, and he trusted that in future the same exertions should not be wanting on his part, and that they would be instrumental in increasing the numbers and promoting the influence of the Association.

Amended Laws and Regulations.

Mr. Soden, of Sunbury, read the following Report of the Committee appointed at Derby last year, to consider the necessity of providing the Association with power to remove members guilty of unprofessional conduct; and also to remedy the want of punctuality in payment of subscriptions:—

At the Annual Meeting of the Provincial Medical and Surgical Association, held at Derby in August, 1847, a Committee was appointed "to consider the expediency of making some alterations in the laws of the Association."

The Committee so appointed, on mature consideration of the subject, approve generally of the laws by which the Association has hitherto been governed, and do not recommend a complete revisal of them; but they suggest to the meeting the propriety of making a new law to empower the Association to expel a member whose conduct may have rendered him unworthy to belong to the Society, and also an alteration in the 23rd law, which will be likely to insure punctuality in the payment of subscriptions.

The Committee are aware of the delicate nature of the first of these propositions; but as the honour and respectability of the Association are intimately connected with the purity of character and conduct of the individual members, they think the Society should have the power of expulsion, in cases of gross violation of professional etiquette and practice. They recommend, therefore, that the following be added to the laws already in existence:—

"That if a member be accused of professional impropriety or misconduct, and a majority of those present at an annual or a special general meeting, consider the charge to be proved, the name of such member shall be removed from the list; but no measure of this kind shall be adopted without the accused having two months' notice of the charge to be brought against him, and of the parties by whom he is accused, that he may, if he so pleases, explain, or defend his conduct."

It is well known that great inconvenience sometimes arises from members omitting to pay their subscriptions till long after they are due; the Committee are convinced that this delay proceeds in most instances from carelessness, or forgetfulness, and they trust that withholding the Journal from such defaulters till their arrears are paid, will remind them of their irregularity, and induce punctuality of payment at the proper period. They suggest the following in lieu of the present 23rd law:—

"Each member of the Association to pay one guinea admission, and the same amount annually afterwards; the subscription to commence from the 1st of January each year, and to be considered as due, unless notice of its being withdrawn be given to the Secretary, or Secretaries, antecedently to the year for which it would be payable. For such subscription each member shall receive a copy of each and all publications issued for the general use of the members of the Association; but if any member's subscription remain unpaid twelve months after it shall have become due, the *Medical Journal*, and other publications of the Society, shall be withheld from such member till his arrears be paid."

J. Conolly.
Thomas Nunneley.
John S. Soden.
Thomas Paget.
Thomas Martin.

It was moved by Mr. Newnham, of Farnham, seconded by Mr. Wilson, of Manchester, and carried unanimously, "That the Report now presented be adopted, and that the proposed regulations be incorporated with the laws of the Association."

Sanitary Committee.

Dr. Conolly, of Hanwell, announced that the Committee appointed on the Sanitary question had no report

to present, it being thought advisable to wait the issue of the Government proceedings.

The PRESIDENT.—Then I suppose the Government Bill will be the Report of the Committee.

COMMUNICATIONS.

The following papers were then submitted to the meeting:—

Local Application of Chloroform.

A case of removal of a tumour from the sole of the foot without pain, illustrative of the efficacy of chloroform locally applied, was communicated by Mr. Spry, of Truro, surgeon to the Royal Cornwall Infirmary; and in the unavoidably absence of that gentleman was read by the Secretary.

On the 9th of this month, a healthy-looking young man, aged 23, from the parish of Breage, was admitted into the Infirmary under my care. He exhibited a tumour on the sole of the left foot, which he stated had been forming about seven years, but which, since December last, had been rather rapidly increasing. The tumour was of an oblong shape, flattened on the surface, firm throughout, but harder in some parts than others, of a natural colour, except at its upper margin, where it appeared to be bounded by a number of small varices. It was two inches long and one wide, extending from the centre of the sole obliquely upward and inward toward the arch of the foot. It was extremely painful when touched, and he could not walk a step without suffering acutely. Considering that this was a fair opportunity for testing the efficacy of *chloroform* as a *local* application. I applied some folded lint saturated with it, to the surface of the tumour, placed a piece of oiled silk over it, to prevent a too rapid evaporation, and retained it in contact with the skin by passing a roller about the foot. In a quarter of an hour the lint was again moistened with chloroform,—the quantity used was under two drachms,—and in about half an hour from the first application, I examined the part. Finding that he could now bear pressure on the tumour without complaining, I proceeded to isolate it by a rapid dissection from the plantar fascia, to which it was firmly attached. The patient did not betray the slightest sign of suffering either by the retraction of the foot, or by the expression of the countenance, and he afterwards assured the gentlemen present that he felt only a very trifling pain at the deepest part of the dissection, but none during the division of the skin, cellular tissue, &c., that pain being, as he described it, "nothing worth talking about." He was not led to expect any particular result from the application of the chloroform. The wound was afterwards covered with lint soaked in warm water, and the oiled silk. The tumour itself was found to be of the fibro-sarcomatous kind, somewhat tuberculated in places, inclining to a grey colour; at its base were several consolidated varices almost as dark as melanotic deposit, but vascular, resembling that morbid enlargement of vessels which Graefe, and other German surgeons have described and nominated "Telangiectasie."

Considering the peculiar sensitiveness of the skin of the sole, this case adds to the testimony already afforded of the efficacy of this powerful sedative when applied to the surfaces of parts intended to be operated on, and tends to remove all anxiety as to any chance of inducing a state of excessive narcotism.

Truro, August 14, 1848.

Mr. Nunneley, of Leeds, made some observations on the effects of the local application of chloroform, and referred to the experiments which he had lately performed. For a notice of these experiments, we beg to refer to the proceedings at the annual meeting of the Yorkshire branch of the Association, which will be found reported in this Journal for June 28th, at page 353.

Employment of Arsenic: Local Paralysis.

A case of paralysis, following the medicinal use of arsenic in small doses, was communicated by Dr. Hastings.

1848. April 1st. Wm. Grimley, aged 16, was admitted into the Worcester Infirmary, having been an out-patient for a few weeks. He has been taking the Liquor Potassæ Arsenitis for seven weeks, in doses of m. iij. three times a day, for an eruption, of a scaly character, on the arms and legs. This eruption is now much better, but he at present suffers from the effects of the remedy; he complains of great weakness and partial paralysis of the upper and lower extremities, with burning pain in the feet; the conjunctiva is slightly inflamed; the eyes are suffused with tears, and there is slight pain in the epigastric region; bowels regular; tongue tolerably clean; urine not very plentiful, and covered with a pellicle. He drank cider while he was an out-patient, but there is no reason to suppose that the paralytic affection can be attributed to any lead contained in it. There is no pain nor tenderness in the spine. He complains of want of sleep at night.

Sumat Ferri Sesquiox., dr. j., bis die. Utatur balneo tepido bis in hebdom. Sum. Pulv. Doveri, gr. v., omni nocte.

12th. This morning he complains of more pain in the feet; and there is spasmodic action of the muscles of the extremities. During the time that he was an out-patient he says he was not always very particular in taking the dose prescribed, but that he never took more than five drops at a dose.

May 3rd. He has now less pain in the feet and hands, but the power of motion is very slightly increased. The conjunctiva is now in a natural condition. Sumat Mist. Ferri Co., oz. j., ter die.

9th. He has more power in the extremities, with less pain. The eruption has appeared in different parts of the body. About four months ago he fell over a gate, and hurt his back slightly at the time.

20th. An eruption of a vesicular character has now appeared on the hands and legs. Appl. Unguentum Sulph., partibus affectis.

June 1st. Vesicular eruption has now disappeared, but the scaly one still remains over a considerable extent. He walks better, and has no pain in the hands or feet, but the hands remain stiff, so that he cannot grasp anything firmly. He is generally much emaciated. Omitt. Ung. Sulph. R. Potassii Iodidi, gr. ij.; Dec. Cinchonæ, oz. j. M. Sumat ter die.

10th. The eruption has partly disappeared, and he slowly gains strength.

19th. Diarrhœa has come on. He walks much better. Sumat. Pulv. Cretæ Co., dr. j., urgente diarrhœa.

21st. He gains strength daily; the eruption has disappeared in a great degree. Galvanism to be applied to the extremities and down the spine.

July 4th. Numbness in the feet still continues, but the other symptoms are gradually disappearing.

8th. Made out-patient. Since this time he has been galvanised about once a week, and is now much improved.

Dr. Hastings observed, that the quantity of arsenic taken was so small in this case, that for some time he doubted whether the paralytic affection could arise from this mineral; but as all the symptoms which usually arise from this remedy were also present in a very remarkable degree on the progress towards recovery, he had come to the conclusion that from some constitutional peculiarity the patient was affected in this unusual manner. The man had nearly recovered the usual power in all the limbs, but Dr. Hastings was desirous of learning whether similar effects, from the use of arsenic in small doses, had come under the notice of any of the gentlemen present.

Dr. Tunstall, of Bath, said,—For the last five years and a half I have been attached to the Bath Hospital, as its Resident Medical Officer, during which time I have had on an average from three to five patients always under a course of arsenic prescribed for the cure of lepra by my superior officers; from my experience I may safely assert, that the safe and efficacious dose is from m. iij., to m. v., twice a day, continued until the physiological effects *commence*, when the disease succumbs. The first appearance of redness of the conjunctiva, with febrile lassitude, constriction of the throat, and mucous irritation of the stomach, are signs that the constitution is under arsenical influence. By closely watching cases, I have never seen any of the severe effects of the protracted use of the remedy, but I am in a position to assert that all the good derivable from arsenic as a remedy, is produced by small doses cautiously watched. Mr. Hunt, in criticising Dr. Castle's case of poisoning by Fowler's solution, refers it to idiosyncracy, and throws a doubt upon the fact of its having been fatal, relating a case where a patient of his own took forty minims thrice a day, with "but slight inconvenience." Will Mr. Hunt, or any gentleman present, say that this dose could have been continued for even three days more, without producing the effects detailed by Dr. Hastings in his valuable communication? In estimating the fatal quantity of successive doses of a poisonous remedy, we have to consider the effects of *climate*, *locality*, and *temperament*, not mere idiosyncracy, for all these are important, in estimating the doses, and period of their continuance. Mr. Hunt states that out of the records of a multitude of cases, in no one instance did it appear that the medicinal exhibition of arsenic, not always cautiously administered, has proved either fatal or seriously detrimental to health, which is more than can be said of any other very active medicine. This, which I copy from the report of the South Eastern Branch of our Association, must not go forth uncontradicted. I cannot admit either the fact or the deductions; where I to do so I should be accessory to the death of thousands. Two cases I will relate:—

Mary Bottle, a healthy young woman, 21 years of age, is now a patient in the hospital for the cure of lepra, on the 6th of July she had prescribed for her the Liq. Arsen. Potassæ, m. iij., twice a day. On the 13th I found her thoroughly prostrate with the arsenical symptoms, and having watched her daily, I know that she only took thirty-six minims in twelve doses. I shall be happy to shew this case to the members, and point out the peculiar glassiness of the conjunctiva, which is characteristic of the *continued* effects of a *previous* exhibition of the remedy, which produced the most marked effects on the specific disease. She has regularly continued the use of the thermal waters of our city, so useful in lepra and in combatting the effects of metallic poisoning, and is rapidly approaching a perfect cure.

The other is that of a young man, now under treatment for the cure of lepra, who discontinued the use of the liquor on the 4th of June, he has still the lassitude, the incapacity for active exertion, and the glassiness of the conjunctiva, and any slight cold reproduces the arsenical effects; he has been using the waters since that period and the skin is rapidly cleansing.

I have to remark that this truly valuable remedy should not be given to patients in the quantities so common in some parts of the country, where a half-ounce bottle, with directions to take a certain number of drops twice or three times a day, leads to much unsuspected mischief; that we ought in the present advanced state of chemical science, to pause before we condemn persons for murder on *post-mortem* evidence of the presence of minute quantities of arsenic, in order that we obtain some particulars of the medical history of the deceased. Had Mary Bottle taken a few more *minute* doses, she would have died from taking, perhaps, one-fourth of the quantity taken by Dr. Castle's patient. Mr. Hunt may deny this, but I think I should have no hesitation in making an affidavit that she would have died from the cumulative effects of small doses of arsenic. In conclusion, allow me emphatically to say, that arsenic is a remedy which produces its beneficial effects, by the slow accumulation of small doses; that these should be omitted on the first appearance of conjunctivitis, or other well-known physiological effects, in however slight a degree; and that where these are absent, the successive doses ought never, in the aggregate, to amount to what would, if administered in one dose, either be fatal, or in quantity approach the minimum fatal dose on record.

An interesting conversation on the subject ensued, after which the meeting adjourned till the evening.

SECOND GENERAL MEETING.

The Members met again, at eight o'clock, in the Assembly Rooms, when the Chair was again taken by Mr. Norman.

American Deputation.

The President said he had great pleasure in seeing so large a number of members present; and as it was possible there were some there who were not able to attend the morning meeting, he would again repeat, on the part of his colleagues, the medical practitioners of Bath, and himself, the great pleasure they felt in seeing them present, and their anxious desire to afford

every information in their power. They would now proceed to the business which was adjourned from the morning meeting. Dr. Wood, of Philadelphia, had attended that meeting, and communicated to it a resolution of the American Medical Association, constituted of delegates from the several States of the Union, accrediting delegates to the English Provincial Medical and Surgical Association; among whom Dr. Wood was especially appointed to meet the members of this Association, with an expression of the desire of the American Medical Association to strengthen the bonds of alliance among medical men throughout the world, and especially with the medical profession of their mother-country, by means of literary and personal intercourse. These sentiments were conveyed to the meeting by Dr. Hastings, the President of the Council, and were most cordially received and responded to by the meeting.

It was then unanimously resolved on the motion of Dr. Hastings, seconded by Dr. Wallis,

"That this Association, duly appreciating the value of the communication made to it by Dr. Wood, and fully agreeing with the sentiments entertained by the American Association, request Dr. Wood to convey to them the thanks of this Association."

The PRESIDENT then said,—Dr. Wood, the Association, taking into consideration the communication made by you this morning from the American Medical Association, have passed a resolution in which they have desired me to express to you the appreciation which we have of your Society, both as regards medical science in general, and the compliment which it has paid to this Society in particular. I have also been requested to express to you the high feeling which we entertain towards your professional brethren in America, and how completely we reciprocate the sentiments which you have conveyed to us from them. At the same time also, allow me to inform you, that you have been enrolled as an Honorary Corresponding Member of this Society.

Dr. WOOD said—It gives me great pleasure, Mr. President, to be the means of conveying the sentiments of reciprocity of this Association to that of my own country, and I shall return there a prouder man, as being the means of conveying this communication from you. I need not say how very thankful I am for the personal notice I have myself received at your hands, and it shall be my endeavour to do nothing which can disgrace the honour you have conferred upon me.

Dr. HASTINGS then read a biographical notice of Dr. Holme, one of the late Vice-Presidents of the Association, sent by Dr. Charles W. Henry, of Haffield, late of Manchester.

BENEVOLENT FUND.

Mr. NEWNHAM, of Farnham, read the following report of the Benevolent Fund:—

REPORT.

The Committee of the Benevolent Fund rejoice to meet you with more cheering prospects; a new, and on the whole, a successful effort has been made to revive and extend the influence of the Society beyond the limits which it had previously held: and notwithstanding that the pressure of the times, and the depreciation of every man's property, and the consequent diminution of income and disturbance of resources common to almost every individual, have operated grievously against their prosperity, yet they are able gratefully to record that the knowledge of their agency and their design has been diffused, that the interest on their behalf has been extended, that the number of their friends has been augmented, and that their pecuniary resources have been increased beyond their most sanguine expectation.

Yet your Committee cannot disguise from you the fact, that this knowledge, and this influence, and these resources, are not as yet what they might be, considering the number of their professional brethren who are able each to do a little, and the number and the urgency of the cases they are called upon to relieve; they cannot disguise from you the fact, that as yet, the Donation Fund is not available for the relief of present misery, and cannot be so for some years, unless a greater effort be made to bring it up to that sum, at which the wisdom of the Association has fixed that the income arising from its capital may be distributed in the relief of the necessitous; and they cannot disguise from you another fact, that in doling out relief from their Subscription Fund, they have been obliged to calculate the measure of that relief rather by their power to give, than by their conviction of what was required to afford adequate assistance. Your Committee, therefore, would earnestly entreat all their friends to keep constantly in view the necessity of supporting and of increasing the funds and the efficiency of each department.

As another motive for so doing, your Committee would mention the fact, that every year places some portion of their funds in a position in which they are no longer available. Every year is marked by *mortality* among their friends; and those friends are exposed like other men, to such change of circumstance, and such personal or family trials, as cripple their resources and render them unable to continue their wonted support; while the self-same causes, mortality on the one hand, and adversity on the other, are constantly augmenting the number of claimants upon their resources; hence the great importance that each one should work while he has the power, and contribute something towards the permanence of so invaluable an institution.

Your Committee have termed their institution invaluable, and they have done so advisedly; because it extends relief to worthy objects, to worthy objects in deepest distress, and for whom no other mode of relief is available: and they would further add, that by a trifling sacrifice from all their Associates, their funds would be immediately placed in such a position as to enable them to give relief in some degree proportioned to the necessities for which it is claimed.

During the past year the number of cases relieved has been somewhat less than during the preceding, yet the extent of their destitution, and the urgency of their misery has been such as very greatly to exceed

the power of administering adequate succour; they cannot therefore but express their earnest hope, that you will enable them in future to do more for supplicants, whom could you but see and hear, they are fully persuaded your hearts and hands would be largely extended.

Your Committee would especially present their thanks to those individuals, and particularly to those ladies, who have during the last year so considerably promoted their object by collecting donations from their friends. They would remark, that even in the earlier days of the Association, the ladies of Worcester, of Warrington, and other places, have been the foremost among their indefatigable friends; and they would earnestly entreat these ladies generally, not to be weary in well-doing, but to apply themselves to this truly feminine pursuit, to become "ministering angels," to the sorrowing and the destitute, and to afford the institution, especially the Donation Fund, the benefit of their untiring exertions, and of their unsurpassed benevolence.

Your Committee finding it necessary to isssue a new edition of their Rules and Regulations, have carefully revised the former ones, and while they have retained their entire spirit, they have made certain changes which altered circumstances, or twelve years' experience have appeared to render advisable; such revised Rules are now ready to be issued to any person on application to the Secretary.

Your Committee desire to record their grateful sense of the services of their late Treasurer and Secretary, Dr. W. Conolly, and anxious to connect his name as closely as possible with their institution, they have intreated him to become one of the Trustees to the Fund; to this arrangement he has kindly assented, and the appointment only requires your sanction by the adoption of this report.

Finally, your Committee trust, that in humble imitation of the divine author of benevolence, you will never turn aside from the cry of fraternal distress, and that the blessing of the sick, and the unfortunate, of the destitute widow, and the helpless orphan, may rest upon your future path.

JOHN BARON, M.D., President.
WILLIAM NEWNHAM, Hon. Sec. and Treasurer.

Dr. Thompson, of Stratford-on-Avon, moved, and Mr. J. S. Bartrum, of Bath, seconded the following resolution:—"That the Report now read be received and adopted, and that the thanks of the Association be given to the Managing Committee for their exertions in carrying into effect this important branch of the Association."

Dr. Cowan, of Reading, said, before the resolution was put, he wished, even at the hazard of being supposed to sound the raven's note, to offer an observation or two. He maintained that the history of the Benevolent Fund was a disgrace to the profession, and that they would never carry out its purposes on a scale commensurate with the magnitude of the Association, so long as it was based upon the voluntary principle. It ought to form an integral part and be connected with all their proceedings, so that the principle of benevolence might be manifested in a way somewhat worthy of that great Association. He always listened with pleasure to the Report, and felt grateful to those who undertook the labours of the officers of the Fund, but yet he conld not help saying that the Association appeared to him to be guilty in this matter, and that the balance sheet of the Benevolent Fund, would shew a far more gratifying result if it were made a part of the proceedings. That he trusted would be the case at no distant time; and though he would make no distinct motion on the subject, at present, he would, as opportunities presented themselves, continue to express his sentiments, assured that the adoption of these views would realize an amount far beyond that which had ever been raised on behalf of the Benevolent Fund.

The resolution was then put and carried.

Dr. Conolly, of Cheltenham, said he had peculiar pleasure in moving the resolution which had been put into his hands, and he felt highly honoured that it had been confided to him to make the proposition. It was to this effect:—"That the cordial thanks of this meeting be given to Mr. Newnham, of Farnham, for his unwearied exertions in promoting the interests, and increasing the amount of the Benevolent Fund, and that he be requested to continue his valuable services as secretary." He (Dr. Conolly) had said that

he felt peculiar pleasure in proposing this resolution, and some pride, because he had himself been the unworthy servant of the Association in this matter for several years. He felt how inadequately he had performed the duties of his office, and was anxious to find a successor. He believed they were indebted to their excellent friend, Dr. Hastings, for pitching upon the right man; for he it was who solicited Mr. Newnham to undertake the office. He consented to do so, and how he had fulfilled its duties they had that night seen. He (Dr. Conolly) hoped that Mr. Newnham would continue his services, and that the Association might for many years enjoy the benefit of the zeal and ability which he had displayed in forwarding the cause of the Institution. He quite agreed with the gentleman who had just spoken that the present state of the Benevolent Fund was a disgrace rather than an honour to the profession, but if that gentleman knew, as he did, the great good which was done by these small means, he was sure that all would be most anxious to contribute, however limited their means might be. Appeals were constantly being made for aid from the fund; the good which was accomplished by these small donations encouraged them to persevere, and he firmly believed that they would go on till this fund became not a disgrace, but an honour to the profession. Something had been said respecting making the subscription compulsory; but that plan had been several times before proposed, but always rejected, and he, for one, had no wish that it should be made compulsory. How much might be done if every member would contribute only the small sum of five-shillings. He had that day, like many more, been a partaker of the hospitality of the members of the Association in this city—and he was quite sure that in no city had they been more hospitably and kindly entertained—he had met ten gentlemen who, with the exception of the host, were all strangers to him. He had there spoken of the Benevolent Fund, and mentioned what might be done with a five-shilling subscription, provided it were general. Such was the contagion of benevolence, that every gentleman he saw at the table, except one, subscribed five shillings, and that one exception gave a guinea, which sums he should have much pleasure in handing over to the Treasurer. He mentioned this circumstance to show that if the Benevolent Fund were more generally known, there were none who would refuse to give it their assistance; and if the members of the Association could only see the letters of grateful thanks which were constantly being received, their zeal on behalf of this fund would, he was sure, receive additional stimulus. He had also the pleasure of enlisting two new members, whose subscriptions he should presently hand over to the Treasurer, and he would only add, that if the same exertions which had hitherto been made were continued, he was satisfied that the Provincial Medical and Surgical Association would be found to be doing immense good, and, more especially, that branch of it with which their friend, Mr. Newnham, was connected. For himself, he would only say that he had been attached to the Associatiou from its commencement, that his attachment to it increased year by year, and that he hoped to live to see it flourish yet more and more.

Mr. ORMOND, of Bath, said the zeal and energy displayed by Mr. Newnham were deserving the most cordial thanks of the members, and he therefore had great pleasure in seconding the resolution which had been proposed.

The PRESIDENT, in putting the resolution, said he hoped the contagion which Dr. Conolly had spoken of would spread itself to every member, and that their Benevolent Fund would prove to be an antidote to poverty, as complete as vaccination was to the small-pox.

Mr. NEWNHAM, on rising to return thanks, said that since he had been in the room, he had been reminded that three years ago, at Norwich, he had pledged himself to give the members no peace till the Benevolent Fund was established on a basis worthy of the Association. He spoke with pride and pleasure then as an individual but now as an officer of the Society he felt it to be his duty to do all in his power to increase its emoluments, and to advance its interests. He well remembered the pledge of which he had been reminded, and he again renewed it, for while life and health were spared to him, and as long as he was able to stand up and advocate the cause of the Benevolent Fund, so long would he be found at his post, and never would he give peace to the members of the Association till he had placed that Fund in a position on which he could look with pride upon it. Truly obliged as he was for the vote which had been passed to him, he would only say that as he felt their kindness, so he would endeavour to deserve it of them for the future. Mr. Newnham then proceeded to give a sketch of the history of the Benevolent Fund, and concluded by saying that it was for objects of distress, such as he had enumerated, that he asked the sympathy, the active benevolence, and the self-denying and untiring pecuniary contributions of the members.

Dr. Shapter, of Exeter, moved "That Charles William Bell, M.D., of Manchester, be requested to deliver the Address in Medicine in 1849."

Dr. Cowan, of Reading, seconded the motion, which was carried unanimously.

Dr. Ranking, of Norwich, moved "That Francis Sibson, Esq., of Nottingham, be requested to deliver an Address on some subject in Physiology at the Anniversary Meeting of 1849."

Dr. Mackness, of Hastings, seconded the motion, which was carried unanimously.

PROVINCIAL MEDICAL SCHOOLS.

Dr. BUDD, of Bristol, said he wished to call the attention of the members to a subject which he conceived affected the interests, if not the existence, of the Provincial Medical Schools of the kingdom. A bye-law had been passed under the recent charter of the College of Surgeons, by which it was laid as a necessity, in order to become a Fellow of that College, that three years of the curriculum of every candidate should be passed in attendance on one of the London schools or

hospitals. Such a regulation was unfair and unjust to the medical staffs of provincial schools, and to the surgeons of provincial hospitals. He knew that it was the custom of some metropolitan practitioners to make light of their provincial brethren, and that it was said, to use the words of an eminent member of the profession, that we did not sell a good article. Whether that was the case or not, he would not undertake to say; he was not there to trumpet forth their own fame; all he asked was, that the provincial schools and hospitals should have fair play and no favour. If a young man were sent up who could not pass his examination, let him be rejected, but at least let them not be deprived of the chance of competition. Monopolies had of late been going out of fashion; and he for one was so far in favour of free trade, that he thought competition would produce as good fruits in this, as in any other department of policy. If this bye-law to which he had referred were allowed to stand, it must ultimately break down the Provincial Medical Schools, and deprive their hospitals of students altogether. There was a great number of young men who were ambitious of the highest honours the College could confer, and who would, under this regulation, obtain their education in London. Besides these, there were many others who, having no distinct views at first, but whose course would be regulated by their degree of success in their studies, would be unwilling to do anything which would disqualify them for going for the Fellowship. The result would thus be, to draw off all the students from the country to London, and therefore he thought it desirable that some steps should be taken to prevent such an occurrence. In the first place, all the opportunities granted by provincial hospitals, some of which were as fine as any in London, would be thrown away; but in the next place, there was a yet greater hardship to provincial men, many, if not all, of whom were as anxious for the interests of the profession, as their brethren in London. Those gentlemen who were in large practice, who desired to investigate cases, to make notes and observations of particular facts, could not carry out their plans without the assistance of intelligent pupils. But if they were to be deprived of all assistance of that sort—if all medical pupils were to be drafted off to London, and by the unhallowed principle of centralization to be confined to that great Babylon—if all provincial investigations were to be done away with, he said it was both injurious and unfair to the provincial part of the profession, and he had no doubt that the College of Surgeons had only to have the matter properly represented to them to do away with the obnoxious bye-law. All he asked for the provincial schools and hospitals was, a clear stage and no favour; and if they were to go down, let it be done in a fair way. The great object of this Association, as he understood, was the protection of the provincial practitioner, and therefore he asked them to take up this subject—to take it up, as he had said before, with a view to seeing that this contemplated injustice should be done away with. He was glad to see that the London College had acknowledged the principle that practitioners in the provinces were entitled to support equally with those of the metropolis, and that a provincial surgeon was to preside every alternate year at the annual dinner. At the last dinner of the Fellows, "Success to the Provincial Medical Schools" was given, with three cheers, and other expressions of warmth; and he hoped the cordial way in which that toast was received was a proof of their sincerity, which they would now have an opportunity of showing in a more practical way. In conformity with these remarks, he begged to submit a resolution to this effect:—

"Having observed that according to one of the bye-laws of the College of Surgeons regulating the course of study required of those who desire to become candidates for the fellowship, three years of that course must necessarily be passed in attendance on London schools or hospitals, this Association begs most earnestly to protest against such regulation, as introducing a principle hitherto unknown in the bye-laws of the College. Up to this time persons presenting themselves for examination to the College, have not had any questions put to them as to whether their education were obtained in London or in the country; and this Association would beg respectfully to impress upon the Council of the College how desirable it is that the same spirit should continue to govern the regulations to be observed by all persons who shall present themselves for examination, whether for the membership or fellowship, the examination the candidate may be able successfully to undergo, being as heretofore the test of qualification."

Mr. Martin, of Evesham, seconded the resolution.

Mr. NUNNELEY, of Leeds, said the bye-laws of the College were as yet comparatively inoperative, on account of the fact that the parties educated at provincial schools were not yet of sufficient age to present themselves for examination according to these regulations. But it was of importance that the provincial practitioners should at once express an opinion upon the matter; they had continually done so upon other subjects, and it would not certainly be right tacitly to allow the institution of a rule which would practically and completely put aside all provincial education. It appeared to him that the London gentlemen had passed this law to give an advantage to themselves; for they, being in a majority, had made it imperative that three out of six years should be passed under their tuition; and had thus, *de facto*, asserted that the gentlemen in the provinces were unfit to educate medical men. All that was asked was, that there should be the same examination for the country as for the London students, and on the answers should depend the question of fitness. He, for one, would not quietly sit down under the imputation of any scientific inferiority to their London brethren. Let them enjoy all the advantages which a metropolitan practice could give; but let not those of the provinces, by any self-imposed laws, for the advantage of these gentlemen, undergo any thing like this assumed degradation.

Dr. Tunstall supported Dr. Budd's resolution.

Mr. MARTIN, of Evesham, said the resolution only

touched one feature of the exclusiveness of the London College. Provincial surgeons were excluded from the Council, and he would ask whether it would not be well to notice this point also?

Dr. Budd quite agreed in the spirit of the remarks of the last speaker; but the constitution of the Council was settled by the charter, whereas the grievance of which he complained was one of the bye-laws.

After a few words from Mr. G. Waldron, of Bath, in support of the motion,

Mr. Bottomley, of Croydon, moved that a petition be presented to the House of Commons from this Association, praying an alteration in the charter of 1843. It was little good applying to the College for any alteration, and therefore he suggested an application to the House of Commons for an alteration of the charter of 1843.

Dr. Shapter, of Exeter, supported Dr. Budd's resolution, because putting aside the *status* of the provincial hospitals, he felt it would be a most cruel thing to force young men into a three or four years' residence in the modern Babylon, and to expose them to all its temptations, while they were deprived of the advantage of guides and the comforts of home.

Mr. Garlick, of Leeds, maintained that a full proportion of all the advances made in science might be claimed by provincial men, and that among those who had stood the present examinations of the College of Surgeons and the London University, a full share of those who had taken the highest honours had been educated at provincial schools.

The President said, that with regard to the practical surgery of the hospitals of London, he believed that they afforded opportunities in a greater degree than those of the provinces: and, therefore, if the resolution assumed that a young man could be educated at a provincial hospital—and he spoke only of the one with which he was himself connected—so as to be competent to pass for a Fellowship, without being at all in London, he should say he could not be so educated. Before applying to the College of Surgeons, they must apply to the Legislature, to alter the Anatomy Bill, so as to get a sufficient supply of bodies to teach anatomy, to enable young men to pass as Fellows, or even Members, of the College of Surgeons. They could not at the present time get a sufficient number of bodies to give a knowledge of practical anatomy to their pupils, the law only providing that in certain cases unclaimed bodies *may* be given for the purposes of dissection. Now, if the law said these bodies *shall* be so given, the difficulty which was at present experienced would be obviated, and with a larger supply of bodies the provincial schools might be able to give that education which he thought was now only to be obtained in London.

Mr. Nunneley, of Leeds, and Dr. Budd, of Bristol, said that in their hospitals the supply of bodies was most abundant.

Mr. Bottomley, of Croydon, moved as an amendment, that a petition be presented to the House of Commons, praying for a repeal of the Charter of 1843.

Dr. Conolly, of Cheltenham, seconded the amendment, but after some conversation, it was withdrawn for discussion as a substantive resolution on the following day, and Dr. Budd's motion was put and carried with one dissentient.

The Meeting separated about eleven o'clock.

THIRD GENERAL MEETING.

At twelve o'clock the members met again at the Assembly Rooms.

The President, on taking the chair, said, that as a great deal of business had been forced into this, the second day of the sitting of the Association, he felt that it would be most unbusiness-like in him to take up the time of the meeting by any additions to the observations he offered yesterday. He would only, therefore, express to those who were not then present, the gratification which his colleagues in the Bath Branch experienced at seeing so many of their brethren present, and again offer to them all the assistance in their power. He had only again to thank the meeting for the honour they had done him in placing him in the chair, and to request their indulgence for the inefficiency and many errors which had occurred in the performance of his duties.

The Address in Medicine.

Dr. W. Davies, of Bath, then read the "Address in Medicine," which embraced an admirable account of maculated fever, its diagnostic characters, and the relation of sanitary measures to this and other forms of fever.

Dr. Robertson, of Northampton, moved, "That the thanks of the meeting be given to Dr. Davies, for his able and eloquent address, and that he be requested to allow the same to be printed." He said the applause which had followed the reading of Dr. Davies' admirable paper had convinced him, that the pleasure he had himself experienced in listening to it had been generally shared by all present. He had never listened to a more admirable production, which appeared to him to be particularly valuable in one point of view at this time, when sanitary reform was so much the fashion. It was of great importance that medical men should not take a one-sided view of this subject, and should point out, that the proposed measures of sanitary reform would only remove some of the many causes of disease which were in existence.

Mr. Soden, of Sunbury, said he was sure their could be but one opinion as to the interesting address which had been delivered by Dr. Davies; and, fully concurring in the observations of Dr. Robertson, he had great pleasure in seconding the resolution which had been proposed.

Dr. Davies said he could only express his great gratification that the address he had submitted had met with the approbation of the members, and how very readily he consented to the request which had been made that it should be published.

Poor-Law Medical Relief.

Mr. Cantrell, of Wirksworth, explained what had been done by the Committee appointed at the last

Anniversary Meeting, at Derby, on the subject of the remuneration of medical officers of Poor-Law Unions. From Mr. Cantrell's statement it appeared that the Committee had coalesced with the Poor-Law Medical Convention, and that a deputation had waited on Sir George Grey, the Home Secretary, and laid the subject before him.

Dr. Hodgkin, of London, Chairman of the Committee, added a few facts to those stated by Mr. Cantrell. The Committee had addressed various questions to the Poor-Law medical officers of the Kingdom, and had received answers from upwards of 800, accompanied by various suggestions. The suggestions had been embodied in a series of resolutions, which were intended to be moulded into a memorial for presentation to Sir G. Grey, and previously to its presentation, application was made to the College of Physicians, the College of Surgeons, the Apothecaries' Company, and the Council of this Association, to lend their sanction to these representations. On the presentation of the memorial to Sir George Grey, he listened to the deputation by whom it was presented, and stated that the whole subject had been referred to Mr. Charles Buller, President of the Poor-Law Board. The last step taken by the Poor-Law Medical Convention was to appoint a deputation to represent that body at this meeting, and he (Dr. Hodgkin) had much pleasure in saying that there were several gentlemen in that assembly, whom he could not do better than introduce to the meeting, in order that they might have an opportunity of stating what had been done.

The following gentlemen formed the deputation from the Poor-Law Medical Convention:—Mr. Martin; Mr. Lord; Mr. Peter Martin; Mr. Cantrell; Mr. Bottomley; Dr. Hodgkin; and Mr. Stedman.

Mr. Lord, Secretary to the Poor-Law Convention, produced the following resolution passed by the Convention, as his authority for appearing at the meeting that day:—"On the motion of Peter Martin, Esq., seconded by John Lidelle, Esq., it was unanimously resolved—'That the delegates deputed to attend the meeting of the Provincial Medical and Surgical Assaciation, be requested to solicit the Association to further the objects of the Convention, by passing a strong resolution approving of the plan of amelioration suggested by the Committee as appended to the memorial to Sir George Grey; and further, that the provincial papers should be influenced by the members of the Association with the view to forward the cause of the Medical Staff.'" Mr. Lord here expressed at some length the claims of the medical affairs of the Poor-Law.

[The plan alluded to in this resolution was published in the last number of this Journal, and will be found at page 435.]

The President said that he had prepared some observations on this subject, but he was fearful of occupying too much time yesterday, and that he should also be anticipating the observations of other gentlemen. He had himself been for twenty-five years surgeon of the parish of Walcot, which comprised about half the city of Bath, and he could bear his testimony to the necessity which existed for the steps which had been taken for the protection of the medical officers of the Poor-Law Unions.

Dr. Cowan, of Reading, moved the following resolution:—

"That this meeting, having fully considered the present false position of the Poor-Law Medical Officers, is of opinion that the interests of the profession, of the sick poor, and of the rate-payers, will be essentially advanced by the plan of amended legislation, deduced from returns of facts and suggestions received from Poor-Law Medical Officers throughout the country, and appended to the memorial recently presented to Sir George Grey by the Convention of Poor-Law Medical Officers. It therefore pledges itself to use its continued influence in support of the plan, and to memorialize the Government, in order that it may be embraced in any new measures which may be enacted."

He was convinced the subject of the remuneration of medical officers, under the Poor-Law, was one of the most important to which the attention of the Association could be directed. Those gentlemen had not only a right to be paid for their labours, but he thought their self-denying exertions entitled them to the most liberal consideration. The present state of things was such as ought not to continue for another hour, and he did hope the Association would struggle, not by its political influence, but by the force of moral combination, to obtain an alteration of the present system.

Dr. Wallis, of Bristol, in seconding the resolution, advised the medical officers engaged on the Poor-Law to confine their attention to the point of obtaining adequate payment from the Government without any stipulation for extra charges for midwifery and surgical attendance; in fact, to seek to place themselves on the same footing as Army and Navy surgeons.

After a few remarks from Mr. De la Garde, of Exeter, and Mr. J. Parsons, of Beckington, the motion was put and carried.

Dr. Hastings then proposed the adoption of the following memorial to Mr. Charles Buller, President of the Poor-Law Board:—

To the Right Hon. Charles Buller, President of the Poor-Law Board.

Sir,—The attention of the Provincial Medical and Surgical Association, at several successive meetings, has been seriously called to the present unsatisfactory state of Poor-Law Medical Relief, and at the present time to the plan for its improvement, which has been submitted to Sir George Grey, in a memorial from the Poor-Law Medical Convention. The Provincial Medical and Surgical Association begs leave to express its opinion that the plan thus submitted would be a great improvement on the present system, and whilst it would satisfy the just claims of the Medical Officers, it would lead to a decided improvement in the medical attendance rendered to the sick poor. The Association therefore earnestly hopes that you will give your favourable consideration to this plan, and thus remove a state of things which inflicts great hardship on many deserving members of the medical profession, whilst it

occasionally leads to circumstances, as regards the poor, distressing to human feelings, and injurious to the public health, and thus to the mere pecuniary interests of the community."

In proposing this resolution to the meeting, Dr. Hastings said he reflected with the highest gratification that this Association had been connected with the movement on behalf of the medical officers of the Poor-Law, from its commencement to the present time; that on no occasion had it turned its back upon them, but that day by day, week by week, and year by year, had it endeavoured to promote this cause. And he would fain hope that those exertions had been mainly instrumental in bringing about an alteration; for when they began their labours the Government was indisposed to listen to them, if it was not altogether opposed to their views. Now, however, he thought it might be said that Government was favourable to their wishes, and he thought that the representation of such a meeting as this would have great weight with them.

Dr. Heygate seconded the resolution, which was carried unanimously.

Mr. Flower, of Chilcompton, then suggested that Mr. Bottomley should bring on the subject respecting the College of Surgeons, which had been withdrawn on the previous evening; but, after some conversation, the meeting decided that the papers which had been sent in from various members should, first of all, be read.

Communications.

The following communications were then submitted to the meeting:—

Scirrhous Mamma in the Male.

The following case of scirrhous mamma in the male, reported by Mr. Spry, Surgeon to the Royal Cornwall Infirmary, was read by Dr. Barham, of Truro:—

On the 16th of February last, I was consulted by Capt. L., residing at P., respecting a tumour occupying the situation of the right mamma, which presented all the characteristics of true carcinoma. The patient was 71, of a rather sallow countenance, but a well-formed and robust person. He stated that the tumour had been forming about four years—that it had very slowly increased during the three first, but more decidedly so within the last year, and especially within the last four months. It had given him very little pain until lately, when he felt occasional darting pains through it. It was about the size of a small orange, somewhat irregular as to shape, of a stony hardness, moveable, and of a uniform consistence. The axillary glands being unaffected and the steady increase of the tumour occasioning him much anxiety, I advised him to have it removed. On the 21st, I attended at his residence, with his usual medical attendants, the Messrs. Michell, of Redruth, who having taken a similar view of the case, the removal was decided on and performed very neatly by Mr. S. V. Michell, from whom I afterwards received the following note:—

"Redruth, June 1, 1848.

"Dear Sir,—I have much pleasure in informing you that Captain L. recovered without an unfavourable symptom. The greater part of the wound healed by the first intention, and he is now in good health.

"Dear Sir, yours very truly,

"E. J. Spry, Esq. "S. V. P. Michell."

Captain L. has since called at my house to report himself quite well and in spirits, and thus far every thing has proceeded as desired. He did not wish for any anæsthetic previous to the operation, but sat in his chair with much firmness of mind. The preparation, by the kind permission of the Messrs. Michell, is in my possession, and has been examined by many professional friends, who consider it a good specimen of true carcimona.

Truro, August 15th, 1848.

Medical Topography.

Dr. Barham then read the following paper entitled "Suggestions for an Inquiry into the Medical Topography of England on the part of the Provincial Medical and Surgical Association." That portion of the paper in which the subject of Meteorology was referred to, was illustrated by a series of diagrams, in which the curves of the variation in different localities were accurately laid down, and thus, at once, strikingly representing the more important facts to the eye.

Prefixed to each number of our Journal is a brief statement of the principal objects of this Association. These are divided into five sections, the second and third of which are as follows:—"Increase of knowledge of the medical topography of England through statistical, meteorological, geological, and botanical inquiries; and investigation of the modifications of the endemic and epidemic diseases, in different situations, and at various periods, so as to trace, so far as the present imperfect state of the art will permit, their connections with peculiarities of soil or climate, or with the localities, habits, and occupations of the people." The importance of these objects no one here will dispute, and the design entertained by the founders of the Association, in giving them so prominent a place, was alike noble and judicious; the work to be done being calculated to confer the highest honour on the body which might effect it, and being such as could scarcely be effected except by such a body as they intended this Association to be, and such as it has become. But very little has, I believe, been as yet done by the Association in its corporate capacity, to carry out these objects; and I now venture to call attention to those, in the hope that they may be taken up with a decided purpose, and that an inquiry may be instituted under a well considered plan.

Within the last few years very considerable advance has been made in the science of meteorology, and as far as the observation of instruments and the recording of results are concerned, there is in several localities little to be desired. It may also be admitted that by the registration of deaths, published concurrently with the meteorological results, some light has been thrown on the effects of particular seasons on particular localities. But neither in the meteorological nor in the vital department, has there been any comparison of that precise and detailed kind which is requisite for the practical purposes of our profession. In respect of climate medically considered, the mere statement of mean monthly results conveys very little valuable

knowledge; it is only by the comparison of daily changes, that their relative frequency and rapidity can be ascertained. Then we obtain little or no information respecting the particular spot where the observations are made. Places not a mile apart may present very natural differences in the results even of instrumental observation; but how much more widely do they often differ in those points, which may be expected to be influential on health. For example, how important is the exposure of a given situation to particular winds, the relation those winds bear to bodies of salt or fresh water, and to different tracts of ground. Moreover, in making up our medical estimate, we must take into account the varieties of geological structure and the nature of the waters. Turning to the department of *vitality*, to the *healthiness* of particular places, the returns of the Registrar-General, valuable as they are in a thousand ways, cannot connect even the mortality at all precisely with topography; and with regard to the diseases which do not usually terminate fatally, they give no information. Then again being of very recent date, they are deficient in the element of time, a very essential one for ascertaining the natural influence of any given locality on the human constitution. The *curative* merits of particular places, another object of the greatest interest, can hardly be at all brought out by tables of deaths.

Such inquiries can in fact be carried out only by medical men, and they can scarcely be made to embrace a very wide sphere, except by the exertions of a large and united body. In relation to the health, or rather the diseases of towns, a great mass of information has been collected, chiefly under the auspices of Government; and it is to be hoped that many of the evils introduced by civic cupidity or blunder will be swept away. But were the economy of towns rendered ever so perfect, the course of nature would still hold on; physical agencies would still tend in this place to corroborate, in that to sap, the bodily vigour; here to produce one disease, there another; to ease or to aggravate particular maladies. To institute a systematic inquiry into the nature and laws of these physical agents, is an undertaking worthy of this Association; its results can hardly fail to add another to the many boons conferred on humanity by the medical profession. This is an inquiry in which observation would bear the principal part, and it has already been, in all the ages in which medicine has had any vitality, entered upon more or less earnestly by the masters of that observation, whence have been, and will I believe always be, derived the most valuable acquisitions of the healing art.

Hippocrates, that great man, who has been called the father of medicine, most justly, as he has fixed on what he received from his predecessors as well as on what he gathered by his own labours, the stamp of his own admirable sense and perspicuous reasoning, has left us an essay on the influence of climate, waters, and localities, on the human constitution, which, in its conception, and (making allowance for the imperfect condition of physical science in his day,) in execution too, appears to me not at all inferior to any other treatise of the same nature with which I am acquainted. Taking the region which fell within his cognizance, from Greece, by Thrace and Syria, through Asia Minor and Egypt, he has marked and recorded the effects of the general climates of the several latitudes, and those connected with the particular aspects and elevation of distant localities, in relation to the diet and water used by the inhabitants, and their habits as flowing from the circumstances in which they were placed; and he has traced the resulting health and constitution, not only as it may have been evidenced by the frequency of particular forms of disease, but as more surely exhibited in comparatively permanent characters of bodily organization and mental powers. I dwell with pleasure on the merits of this illustrious physician, because I see in him a conspicuous example of that method of medical inquiry which leads to the most useful practical results. Placed as a sort of superior officer of health, in a position to exercise sanitary inspection over a wide district with authority and dignity, his genius and humanity, in developing and applying the resources of our divine art, had enabled him, in a semi-barbarous age, to set himself to observe with accuracy, and to follow the indications of nature; and he taught men to avail themselves of her curative bounty. He is fond of introducing a little scientific explanation of phenomena, sometimes better, sometimes worse, than the science of succeeding ages, but he seldom allows himself to be run away with by his own opinions.

Nothing can be plainer in the history of physic, than that the introduction of each successive code of laws for health and disease, as each little development of physical science occurred, tended to interfere, for a time at least, with the beneficial progress of practical medicine. In this, our day, several sciences, justly considered to be handmaids to our art, have made rapid progress; still, I believe it will be found to hold good, that neither the most subtle organic chemistry, nor the most minute microscopic anatomy, nor the most admirable physiological deductions, will prove safe guides to the physician in the treatment of disease, though their lights will all of them be useful suspended along the walls of the labyrinth, through which he cautiously advances, holding in his hand the clue furnished to it by the observation of the phenomena of life. So in drawing conclusions as to the relative healthfulness of different localities, this Association would follow the Hippocratic method, by observing what was the total result of the physical influences there at work, calling in the aid of meteorology, chemistry, geology, and whatever accessary science might contribute its quota towards the eventual establishment of general principles.*

For the purposes of our proposition in this department, there are two prominent objects of inquiry. What are the best sites for dwelling-houses in each district of the country? and what are the laws in accordance with which change of residence is to be advised and directed. It will be understood that the investigation which I now urge on the attention of the Association, does not so much regard the effects of residence in places already resorted to for the restoration of health, and appropriated in some sort to the

* The attention paid by Sydenham to atmospheric conditions in reference to epidemic disease, and the more accurate and important observations of Huxham, I would content myself with barely alluding to, as examples from our English medical fathers of the just appreciation of such inquiries.

more opulent classes. What I wish to suggest, is an inquiry which belongs to every neighbourhood, and, more or less, to every rank—its ultimate object being, in the first place, the medical determination what situations are eligible for being inhabited; and, secondly, to introduce change of residence as a well understood and regular department of ordinary therapeutics. Most of us must be well aware, from our own observation, that the beneficial effect of such change, though the distance travelled may be very small, is often most strongly marked. In the district where I myself reside, which is somewhat peninsular, having a northern and a southern sea within six or eight miles of the centre, nothing in the effects of medical treatment can be more striking than the rapid improvement in the state of the general health, often in that of localized disease, consequent on removal. Change would seem to be in itself beneficial, and I have found it well to make my patients oscillate at short intervals from the coast to the inland, or from one coast to the other.

If we turn to the mineral waters of this country, it will be found that the knowledge available to the profession is very much limited, and that the practical application of the treasures of this kind within our reach, is yet more so. Scarce any springs are resorted to, except they be marked by strong impregnation or high temperature; but there are few districts in which chalybeates may not be found; in very many there are saline chalybeates, quite active enough to produce those wonderful effects often secured by the infinitesimal doses of natural mixtures. Even the extreme purity which has been found to constitute the sole peculiarity of many wells of ancient celebrity, is a quality not to be despised. I hope to see the day when medical men generally will allow nature to make some of their solutions, when the professfonal superintendants of the mineral waters of every district, studiously provided in Spain, Italy, and Germany, in order that people of every class may participate in the benefit, will be afforded to this country. Without countenancing the refined absurdities of homœopathy, or admitting the water-cure as a panacea, the truly rational practitioner will do as much as he can by removing all noxious agencies, recommending wholesome diet and exercise in the purest air and most healthy situations, and having recourse when opportunity offers to the laboratory of nature for his drugs. I am fortunate in making these remarks in this ancient and beautiful city, which we may strip in fancy of the accumulated and gorgeous works of man, till we see the druid immersing the neophyte, or gaining credit to his incantations, by the palsy removed by the magic waters; where, in a later age, we may admire the palatial structures and tesselated pavements of the Romans, who made bathing a necessary of life; till gradually, through successive stages of progress, we restore the city to its present magnificence, and admire its healing springs, largely devoted to those hospitals for the poor so characteristic of Christianity. But each age and people has alike given its cordial assent to the Pindaric motto, "*αριστον μεν υδωρ.*"

I have detained you too long, and must hasten to the consideration of the means which seem most adapted to improve our knowledge on those points I have considered as desiderata. A certain number of localities should, in the first instance, be fixed on, which may adequately represent the several distinct varieties of situation in different parts of the country. Accurate meteorological observations should be secured in each of these situations, and the daily results should be compared; that comparison is best effected by curves and diagrams, such as you see before you. Variations here strike the eye where it would be bewildered among a host of figures.

Mr. Glaisher, of the Royal Observatory, Greenwich, has recently published in the *Philosophical Transactions*, a series of corrections, by which these comparisons will be greatly facilitated, and I am happy to say he has entered warmly into the purpose, which I ventured to hope the Association would entertain, and has promised his valuable aid in discussing the results of our observations. I have also reason to believe that the Registrar-General and Mr. Farr will kindly co-operate with us in rendering the investigation serviceable to the profession and the public. Certainly the publications periodically issued thence, and from Greenwich, would very much lighten the expense attendant on such inquiries. The other physical conditions of the chosen localities must at the same time be recorded with precision.

For the purpose of ascertaining the *healthiness* of these situations, documentary evidence should be collected and examined. The parish registers are commonly very valuable, and indeed the only material repositories of evidence of this kind, showing the rate of births and deaths through a long succession of years. I once made an abstract of the registers of the parish of Tavistock, giving these and other particulars for every month through two centuries. These tables were published by the Board of Trade, and the essay which accompanied them is in the Journal of the Statistical Society. The results as to the relative mortality in particular months, and the prevalence of epidemics at particular periods, are highly interesting. A series of such abstracts would form a body of evidence much more satisfactory than most of that, the deductions from which have been lately published by Professor Casper. The health and hereditary disorders of the oldest native families should be inquired into, and the physical peculiarities stamped upon them should be noted. You have seen some of the peculiarities of the climate of the Scilly Islands; it has produced in the islanders modifications of form and colour sufficient to distinguish them among the Cornish. The effects of residence in these localities on strangers, and in particular disorders, should then be learnt, as far as possible from the past, and carefully watched and recorded during a considerable period. The stores accumulated under the existing registration of births and deaths would of course be turned to account.

I have only indicated a portion of the inquiry, or of its useful applications. If you agree with me that these cardinal purposes of our Association shall be vigorously carried out, your Council will doubtless enter readily on the consideration of the practical methods by which success may be best attained.

Dr. Hastings communicated some observations, together with medical testimonials, in favour of Mr. Falkner's new preparation of opium.

Poisoning by Belladonna.

The following case of poisoning by belladonna, reported by W. Jackson, Esq., F.R.C.S., of Sheffield, was read by the Secretary :—

Thomas Greaves, aged 75, a man of thin spare habit, took by mistake a quantity of the extract of belladonna. It was intended that the extract (the quantity sent being five drachms,) should be spread upon a plaster, to be applied to the chest, but the poor old man mistook the verbal directions, and thought the box contained an electuary. The dose taken was represented by a female, who was present at the time, as so small as not to exceed four or five grains. Whether this person was mistaken as to the *quantity* taken is uncertain. This occurred about six o'clock in the evening of July 11th. In a short time the symptoms became manifest, and at seven he had lost the power of articulation, and presented the general appearance of a person seized with slight paralysis. He was quite unable to stand or walk, and his limbs were in a state of tremor and agitation. He became cold, and nearly approaching a state of insensibility; the eyes had a wild vacant appearance; the respiration was laborious and occasionally stertorous, and he moved the body almost incessantly backward and forward, as if his inward suffering (not otherwise expressed,) was very great. At ten o'clock the temperature of the body had increased; face swollen; mouth and throat extremely dry; and insensibility more complete. Castor oil had been given, but was rejected. One of the attendants stated that nausea prevailed at various times. No active delirium was manifested, but from the general appearance of the eye and features, no doubt that peculiar derangement existed, subdued partially by the pressure upon the cerebral organ, so as more nearly to approach the character of apoplexy. At six the following morning, he appeared considerably exhausted, but had still sufficient power to take some wine and water, and for the first time indistinctly uttered a few words. His mouth and fauces at this time, to give the language of an attendant, were as *dry as a chip*. His face was so much swollen and red, as to quite change his usual appearance. His daughter remarked that the *wrinkles of old age had disappeared, and he appeared much fatter than usual*. Between nine and ten in the morning, he appeared quite exhausted, and his friends becoming alarmed, called in the assistance of Mr. Pearson, surgeon, of this town, who found him *in articulo mortis*. He died at eleven, being seventeen hours after having taken the extract.

Autopsy.—Mr. Pearson requested my assistance in the examination.

The external appearance presented nothing worthy of remark. The venous system of the cerebrum was in a state of the greatest distension; bloody points were most numerous on slicing the cerebral mass; the cavities of the brain were excessively distended with fluid. As we approached the base of the brain, more or less of softening of the structure presented itself; this condition was especially conspicuous in the cerebellum and medulla oblongata. The effusion completely distended the spinal canal, and surrounded the medulla. The congested state of the vessels of these parts of the nervous centres was singularly great. The lungs were in a highly congested state, and uncollapsed, and in colour almost black. Although he had been suffering from chronic bronchitis for some months, yet the inner coat of the air-tubes presented no abnormal appearance, excepting a relaxed state of the mucous coat. The heart was natural; the blood was fluid, except a slight partial coagulation in the left ventricle. There was no abnormal appearance in the alimentary canal, except in the stomach, on the mucous coat of which organ a remarkable alteration of colour and texture was presented; this dark brownish, or rather black appearance of the mucous coat, occupied several square inches of the greater curvature, not extending as high as the cardiac extremity. In this situation, also, the texture of the organ, (*i.e.*, its mucous coat,) was softened, but not ulcerated. The colour in this case was more approaching to blackness than that purplish appearance which ecchymosis displays. The stomach was empty, except a quantity of grey and yellowish mucus. We thought the odour of belladonna could be detected in the contents, but not sufficiently so to justify our giving a positive opinion.

The points of interest in the case are the sudden effect of the narcotic upon the organs concerned in the articulation and voice. A question here presents itself. Was the compression of the origins of the hypoglossal and pneumo-gastric nerves the result of the effusion of fluid?—or, did such effect occur previously? This poor debilitated old man had been suffering under an affection of the chest, probably chronic bronchitis, for a long period. That disease, together with his great age, would place him under unfavourable circumstances, as regards the effects of a poisonous dose of a narcotic.

The course of the symptoms presented several of the characteristics of the early progress of a case of highly congestive fever. The first invasion of those symptoms, according to the testimony of the attendants, was marked by sudden prostration of the vital energy, loss of temperature, obscuration of the intellectual powers, embarrassed respiration, loss of the power of articulation, and probably depression of the circulation. Re-action gradually supervened, and the increased force of the circulation was marked by redness and a full bloated appearance of the face. But although this invigorated state of the circulation became fully established, yet the primary impression upon the centres of the nervous system continued unabated, and gradually increased, until the interruption of the supply of nervous influence to the vital organs finally extinguished life.

That the chief action of belladonna is excited upon the medulla oblongata I think this case substantiates; but it is highly probable that its influence is more or less extended to the cerebellum. I would therefore, advise the treatment in such cases, after evacuating the stomach, to consist in cold affusion, (perseveringly used,) to the head, and especially to the occipital region and back of the neck, as in cases of poisoning by hydrocyanic acid. We may also hope for advantage from cupping in the same situation. The stomach is easily excited, and emetics act with facility, and this would render the use of the stomach-pump unnecessary, provided the poison had been taken in a fluid form. As regards the doses of belladonna, great variety of opinion and practice prevail. Some have ventured to give three grains for a dose, whilst others

have limited it to a smaller quantity. I have given this remedy pretty extensively, but have not been able to increase the dose beyond two grains.

Allow me to ask, can there be any reasonable doubt, considering all the circumstances of this case, as to whether Thomas Greaves died from the effects of belladonna? There was evidence produced, that he took but a small quantity—it was believed by some, amounting to not more than four or five grains. This was probably a mistake. But supposing he had taken five grains, circumstanced as this poor old man was, we are surely entitled to infer, from the symptoms narrated by the attendants, and the *post-mortem* appearances, that belladonna was the cause of his death. The Jury returned a verdict, "Died from natural causes."

Petroleum in Cholera.

Dr. Tunstall, of Bath, read the following observations on the use of petroleum in cholera:—

Two years since I wrote to Sir Charles Napier, then Governor of Scinde, recommending the use of petroleum in Asiatic Cholera, I was led to believe that it might prove useful, *first*, from its chemical nature and properties, *secondly* from its stimulant effects upon the system, and thirdly, because Dr. John Davy had proved by direct experiment that the respired air of cholera patients contains a much smaller proportion of carbon than is sufficient for the proper purification of the blood.

In the course of my reading on the disease, I was struck with the fact, that persons employed in the manufactory of charcoal at Marseilles, and elsewhere, were singularly exempt from the disease in 1832. Mr. Ritson, of Manchester, in the *Lancet* of August 4th, brings under our notice similar facts in relation to the charcoal porters of the Island of Malta; and states in addition, that the crews of African traders, whose water is preserved in charred casks, escape in a great measure the dysentery of the coast.

The *carbonizing plan* of treating looseness of the bowels, or in other words the exhibition of the alkaline carbonates of magnesia, lime, and ammonia, is almost coeval with the practice of physic as a science. These remedies act by neutralizing acrid secretions, and evolving carbonic acid; where, as sometimes happens with magnesia, they produce a purgative salt, their use is contra-indicated.

Now, in cholera asphyxia, we have a disease in which acid evacuations are the prevailing symptom, the respired air is deficient in carbon, and the system rapidly succumbing to a fatal putridity, the blood and other fluids changed in their character, and death, I believe, resulting from an accumulation of impure blood in the lungs.

If, therefore, those escaped whose clothes were impregnated with charcoal dust, and who from necessity must daily have introduced portions of it into their digestive organs, and if the air respired is in the condition described by Dr. Davy, I do not think I am wandering from a legitimate theory in prescribing a medicine which, in a given quantity, contains a larger proportion of pure carbon than any other known substance.

This theory Dr. Soulby, of Dover, has called upon me to explain. I am aware that, in the explanation of the effects of remedies, we are apt to render our meaning unintelligible by the use of terms which, however satisfactory to our own minds, are liable to misconception by others. Dr. Soulby particularly refers to the following passage in my letter to Sir Charles Napier:—

"In the petroleum, we have a medicine which acts primarily as a powerful stimulant. Secondly, by supplying the system with a due proportion of carbon for excretion, while its effects being produced by means of the absorbent system, it acts beneficially as an antiseptic, preserving the frame from the rapidly fatal effects of this horrible disease, by evolving carbonic acid from the lungs."

If, (says Dr. Soulby,) the system is already overcharged with any element, we cannot expect to relieve it by administering more of the same.

To this I reply, that my own experience in 1832 showed me the rapidly fatal effects of the disease; and its putrescent character was verified by *post-mortem* examinations, conducted by myself in the presence of the late Dr. M'Intosh of Edinburgh, and other practitioners; that my observation of the effects of petroleum, in other diseases, convinced me that it was not only a powerful stimulant, but a highly carbonized antiseptic. Its first action is stimulant; its odour is perceptible in all the excretions; its secondary and most important effect is, that it supplies the system with a due proportion of carbon for excretion. Dr. Soulby presumes that beause the system is already overcharged with carbon, highly carbonized remedies can do no good. In this I differ. If an important excretion is defficient in its peculiar elementary principle, I think we are justified in the administration of a remedy containing that elementary principle.

In June last, Mr. Guthrie brought under the notice of the Medico-Botanical Society, that the Cossacks in Circassia had used this remedy, which is found native in the East Indies and Persia, with singular good effect; and this not upon mere rumour, but upon the report of Dr. Andreosky, who had himself employed it. I then, by Mr. Guthrie's advice, published my communication to Sir Charles Napier, who had previously caused it to be extensively circulated in the East, by which means the Cossacks obtained their knowledge of the remedy. Mr. Guthrie adds, that the priority of discovery is due to myself, and he communicated my letter to the Medico-Botanical Society, advising me to publish it to my professional brethren.

It is singular how the carbonizing plan gains ground. Mr. Ritson advises water to be kept in charred vessels, and a correspondent in last week's *Lancet* extols creosote, the active principle of which is carbon. If we adopt the theory that in cholera the impurity of the blood arises from its containing too much positive electricity, we can readily explain the action of the hydrocarbons, which are negatively electric bodies, and which, on their introduction to the system, tend to restore the balance of electricity to its due standard. Thus, if the system, being in a state of positive electricity, does not eliminate carbonic acid gas from the lungs, the introduction of a hydro-carbon, or other negatively electric body, will enable it to do so; without some such explanation as this, it would be difficult, perhaps, to account for its action. We must bear in mind that the excretions from the bowels and stomach show an excess of acid, or, in other words, of oxygen, a positively electric condition.

A letter from St. Petersburgh to a gentleman in Manchester, which has lately gone the round of the papers, states "that a very important discovery has been made here recently, which clearly proves that the malady is in the air, and, therefore, quarantines are utterly useless. The air here has had a very singular effect on the magnetic power. Whilst the cholera was at its height, which now the disease the action of the magnet was nearly neutralized, is gradually subsiding, assumes by degrees its former power. A magnet block, which used to carry eighty pounds, during the worst time of the cholera, would not carry above thirteen pounds; its strength has now increased to sixty pounds. The electro-magnetic telegraph at one time would not work at all."

And now, let us notice those remedies which have been extolled as specifics, and, first, brandy. Is not this a hydro-carbon?—are not the essential oils proved by ultimate analysis to be vinary compounds of carbon and hydrogen?—and have not all these been successfully employed in the cure of this disease? In the petroleum we have this binary compound in its purest form; 100 parts contain 85 per-cent. of carbon and 15 of hydrogen, and it is the only one of them that can be administered safely in large quantities; in taste it is balsamic, differing thus from the essential oils, which are more or less pungent, allowing them only to be administered in small doses.

It is much to be regretted that a sophisticated article, formed of coal-tar and oil, should have usurped the place of this remedy in the ordinary shops. A short time since a spurious article was supplied to the Bath Hospital, by a first-rate London house, who I feel satisfied had no suspicion of its being factitious, until I shewed them a specimen brought direct from Barbadoes. Dr. Faraday has given us a sure test, by which we may discover its purity. If sulphuric æther is added to it, the petroleum is entirely dissolved, and the solution is of a green colour,—an effect which is not produced by its addition to any other bituminous products, whether natural or artificial.

Dr. Tunstall exhibited specimens of the genuine petroleum and the spurious article, together with the effects of Dr. Faraday's test on both.

Cholera.

Dr. Cowan, of Reading, read a paper containing suggestions for the Treatment of Cholera, derived from the experience which he had acquired during the former visitation of the disease.

The following extract from a letter, intended for communication to the Council, but received too late for that purpose, was read by Dr. Hastings.

"Dear Sir,—Will you have the goodness to allow the following suggestion to form a part of the deliberation of the Council, viz.:—

"That as another visitation of the Asiatic cholera is apprehended, and as those whose duty it is to attend to public hygiene in this country, are very laudably occupied in endeavours to oppose the approach of this disease, and that, should it appear, they may have in readiness the means of mitigating its ravages, it is submitted that the Association, as a body, should take some prominent part in this movement. To assist in throwing a light on this mysterious subject, I beg to recommend that a prize (a medal, or £10 or £20,) be offered for the best Essay on "The Pathology of Asiatic Cholera."

If the anatomical character and precise changes which takes place in the animal economy were well ascertained, it would point to what we should aim at in the onset of this malady, and lead to a more rational treatment. The present methods of treatment are quite empirical."

Protection from Burns by Fire.

Mr. Crompton, of Manchester, brought before the meeting a discovery of Dr. Smith for rendering articles of clothing, &c., insusceptible of taking fire. He stated that all that was necessary was to immerse the article to be protected into a solution, the nature of which had not yet been made known to him. Specimens of lace, printed muslin, paper, hay, wood, and other combustible materials so prepared, were exposed to the action of flame. They were severally charred, but neither took fire, nor was their texture destroyed. Specimens of the same articles which had not been immersed in the solution were at the same time submitted to comparative trial, taking fire readily. The appearance of the several articles was in nowise altered by the action of the solution.

Spinal Disease.

Mr. Hare, of London, exhibited drawings of the case of a young man labouring under spinal deformity, which was communicated at the last Anniversary Meeting. (See *Provincial Journal*, August 11, 1847.)

The patient returned home in May last, so much improved that the deformity was scarcely observable when he was dressed. In a letter he has lately written to Mr. Hare, he says that he is in the enjoyment of good health, and has continued to gain strength ever since his arrival at home, and has not, to his knowledge, got at all worse as regards his deformity than when in London.

Gangrene of the Mouth.

Mr. Hare also exhibited drawings of two cases of gangrene of the mouth.

In the first case, which occurred in 1831, the gangrene destroyed so much of the cheek as to leave an opening nearly round, of a diameter of more than an inch, through which a good deal of the food taken by the child escaped. It subsequently closed, and the child had perfectly good health.

In the second, which occurred the following year, the sloughing was more extensive than in the preceding case; but the true skin was not destroyed. An anchylosis of the upper and lower jaw was so complete that she has never been able to open her mouth since, and it became necessary to remove two of the teeth of the upper jaw, to enable her the better to take food. Although she has not perhaps been so strong as some females, yet she has enjoyed quite an average state of health.

The treatment adopted in these cases was the most close attention to correct the state of the digestive organs by the administration of emetics, mild, but efficient purgatives, and such other means as will be obvious to those who have the management of somewhat similar cases.

Charter of the College of Surgeons.

Mr. Bottomley, of Croydon, moved, "That the following petition be presented to the House of Commons, praying them to repeal the Charter of 1843."

To the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled.

The humble Petition of the Provincial Medical and Surgical Association assembled at Bath

Sheweth—

"That your Petitioners, in common with the great majority of the members of the Royal College of Surgeons of England, strongly disapprove of the terms of the Charter granted to the College in 1843, which they consider injurious to the honour and interests of the members. That the grant of the Fellowship without examination to a selected portion of the members places the remainder in an inferior position. That all gentlemen who became members of the College prior to the recent Charter, attained an equal collegiate rank, and that none of them ought to be deprived of any collegiate rank or status by an *ex post facto* law. That by the Charter all surgeons residing in the provinces, or practising midwifery, are excluded from the Council, and that such exclusion is altogether unreasonable, injurious to provincial surgeons, and discouraging to the study of midwifery, than which there is no more important branch of the medical and surgical profession. That the Charter of 1843 has produced so just and general a feeling of dissatisfaction among the members, that harmony can only be restored to the Colleges by its repeal, and the substitution of another Charter, founded on a more equitable basis. Your Petitioners, therefore, humbly pray that your Honourable House will take such steps as may be necessary to redress the grievances of which they complain, and your Petitioners, as in duty bound, will ever pray."

Mr. Flower, of Chilcompton, seconded the resolution; but, after some discussion, an amendment, proposed by Mr. Soden, of Sunbury, and seconded by Dr. Booth, of Bath, to the effect, "That it is not expedient for this Association, at present, to entertain the question," was carried by a large majority, it being considered that the petition was informal, and that the subject might be otherwise more efficiently dealt with.

Dr. Streeten then rose and said, that he had the honour to lay before the meeting a requisition, signed by upwards of one hundred medical practitioners of the city and county of Worcester, and would proceed, with the permission of the meeting, to read the terms of the requisition. "We, the undersigned members of the medical profession, resident in Worcester and its vicinity, request that the Provincial Medical and Surgical Association will do us the honour to hold an Anniversary Meeting of the Association at Worcester, at as early a period as may be convenient." He had accordingly great pleasure in proposing that the request of this requisition should be complied with, and that the Association should honour Worcester by holding the Anniversary Meeting for the year 1849 in that city. The resolution which he held in his hand expressed also the name of the President elect. He felt sure that the meeting would at once anticipate that none other than the esteemed founder of the Association could, on this occasion, be selected for that office, and begged therefore to move, "That the Anniversary Meeting for 1849 take place at Worcester, and that Charles Hastings, M.D., F.G.S., be appointed President elect."

Dr. Booth seconded the resolution, which was carried by acclamation.

Dr. Hastings, in returning thanks for the honour done to him, said it gave him the greatest possible satisfaction in the prospect of seeing the Association at Worcester next year, and he could assure all the members that no exertions should be wanting on the part of his professional brethren and himself to procure a good meeting. Although they might not hope to rival their friends in Bath, yet, if good intentions and great exertions could ensure a good result, he hoped it would be found that the example which had been shown in this city had not been lost upon them.

It was moved by Dr. Paxton, of Rugby, and seconded by Dr. Soulby, of Dover, "That the thanks of this meeting are due, and are given, to those gentlemen who have read papers and presented communications at this meeting."—Carried unanimously.

Moved by Dr. Heygate, and seconded by Mr. Bottomley, "That the thanks of this meeting be given to Mr. Norman, for the able manner in which he has conducted the business at this Anniversary."—Carried unanimously.

On the motion of Dr. Tunstall, seconded by Dr. Wallis, the thanks of the meeting were awarded to the Mayor, Magistrates, and citizens of Bath, for the kindness and liberality with which they had received the Association.

THE DINNER.

The dinner took place in the evening, in the banqueting-room of the Guildhall, George Norman, Esq., presiding, supported on the right by the Mayor of Bath; the Rector of Walcot; Dr. Shapter; Dr. Wood; Dr. Hastings, &c.; and on the left, by the Archdeacon of Bath; W. Miles, Esq., M.P.; G. Kitson, Esq.; Dr. Conolly; Dr. Heygate; Dr. Daniell; &c.

After the removal of the cloth, "Non Nobis Domine" was sung in excellent style by a party of professional gentleman engaged for the occasion, who enlivened the evening by the performance of several appropriate glees, &c.

The President then gave in succession, "The Queen;" "The Queen Dowager;" "Prince Albert;" "The Army and Navy;" "The Bishop and Clergy of the Diocese," (responded to by the Archdeacon of Bath;) and "The Mayor of Bath," with thanks to him for his exertions to promote the business of the Society.

The toast was acknowledged by the Mayor, who concluded by proposing the healths of "The President, Vice-Presidents, and the Members of the Provincial Medical and Surgical Association."

"The Members of the City of Bath;" "The Members for the Eastern Division of the County of Somerset,"

(replied to by W. Miles, Esq., M.P.;) who proposed the health of "Dr. Wood," of America.

Dr. Wood returned thanks. He said—Mr. Chairman and Gentlemen, It is with emotions that I fear may prevent the expression of all I feel on this occasion, that I rise to thank the present company for the honour they have done me, and more especially for the honour they have done my country through me. (Cheers.) Science, Sir, is universal—it is born of the necessities of our nature, and its objects are to promote the good of mankind; and therefore its cultivators in every clime ought to be brethren. (Hear, hear.) If it be true of the great system of science, that by strong attraction all parts are kept together, it is still more so in its inferior or subordinate relations. Like the planets of the solar system, though constituting a great mass of the stupendous whole, there is a closer affinity to each other than to other parts; so we, as scientific men, have a connection, but as medical men we are bound together by a yet stronger link. We, of America, have the same origin with you, which binds us by a yet closer tie—we have the same climate, the same literature, for we draw all our knowledge (our scientific knowledge I mean,) from almost the same sources; and, therefore, how important is it that we should cultivate the spirit of brotherhood. (Hear, hear.) Standing here as the representative of the profession in America—I may say also as the representative of the intelligence of America, in relation to this country, for I believe I may add that in our land among the well-informed there is a universal prevalence of this feeling towards the mother country—I say, Sir, that we are extremely anxious to cultivate this reciprocal spirit from those in the highest ranks of knowledge to the lowest grades of society. (Cheers.) We have, gentlemen, the fairest race on the earth—we have also the impulse of the Welsh or Celts, the steadiness of the Saxon or German character, and the energy of the Norman race—and we shall go on, unless interrupted by ambition, till all parts of the earth are impregnated with the Saxon knowledge and the Saxon religion, and to such an end I am bound to wish a speedy consummation. (Cheers.)

Dr. Symonds of Bristol, said that, when the Mayor of Bath concluded his speech by proposing the President of the Association, and also the Vice-Presidents and members, they had all felt too modest to respond to the toast, and consequently the health of the President had not been received in that emphatic manner which it would have been had it stood out more distinctly. He was quite sure that such a man as Mr. Norman would call forth those feelings which every one entertained towards his chief; and having, as citizens, already testified their loyalty to the Sovereign, he would now call on them to shew their respect for their President. (Cheers.) To those in this part of the kingdom it was unnecessary to say a syllable respecting Mr. Norman, and those who had come from other parts, were it only for a day, had, he doubted not, caught the same sentiments of respect and admiration as animated all who were favoured with a more intimate acquaintance; he would, therefore, call on them to join him in drinking the health of the President. Drank with "three times three," and one cheer more.

Mr. Norman then said,—Gentlemen, the sin of my ingratitude lies heavy on me, seeing that I ought to have returned thanks when the Mayor of Bath proposed my health as President; but as I knew another opportunity would be afforded me of acknowledging his kindness, I thought, perhaps, it would be better not to occupy your time by interfering with the order of proceeding which has been set down. Gentlemen, it has been my inclination as well as my duty to endeavour to obtain the good opinion of the public; I have had to live by them; but to gain the good opinion of you, my professional brethren, has been my ambition; and if I may take your present demonstration as a proof that I have not altogether failed, I shall feel that I have attained the highest point at which I have aimed. (Cheers.) I will not add more, gentlemen, on that unpleasant subject, self, but will only once more thank you, and wish you all health, happiness, and success. (Cheers.) I will now request silence, while Dr. Daniell proposes a toast, which will, I am sure, enlist the feelings of all present.

Dr. Daniell rose and said,—The progress of time again brings us to this period of our interesting meetings, when, at the request of our valued President, I beg to introduce to the notice of this enlightened assembly, a proposition which will receive their simultaneous response. It is, "Prosperity to the Provincial Medical and Surgical Association, in connection with Dr. Hastings, the President of the Council." (Cheers.) It is well that we should wish prosperity to an Association which was framed through the untiring and zealous aid of its founder to give a stronger impulse, and more systematic direction to professional inquiry, to promote the objects which cultivate science in different and distant parts of the British empire with one another, and with foreign philosophers, one of whom has honoured this meeting with his presence—(cheers)—and to remove disadvantages of a public kind, which might impede the progress of justice and truth. And, Sir, it is gratifying that this meeting has attracted individuals here this evening, who so eminently represent the Church and State; and permit me to say that one of them, well known to me in our Collegiate days, gave an earnest from his solid integrity and high intellectual attainments of his present useful position and unimpeached and unimpeachable character; I allude to Mr. Miles, our county member. (Cheers.) When I look around this festive scene, and observe, wherever my eye rests, men eminently qualified as physicians and surgeons to discharge their responsible professional duties with advantage to the public,—when I bring to mind the many laborious works that some have compiled, no less than the talent displayed by others as teachers of Medicine, Anatomy, and Surgery, in provincial cities, it is quite clear that the glory of our professsion is not limited to the great metropolis! (Hear, hear.) But it is not the profession only that is benifitted by these Associations. The public at large receive a vast amount of relief from their labours and assiduity. Be assured, when disease flits over the ill-ventilated and impoverished tenements of the poor, the apartments of the palace are by no means exempt

from its influence. (Hear, hear.) Then are the attention and professional learning of the physician and surgeon required to yield those remedies best adapted to avert disease, and thus to prolong "the schemes of to-day and the hopes of to-morrow"—to prolong—

"That time which hurries on with a resistless unremitting stream,
Yet treads more soft than e're did midnight thief,
That slides his hand under the miser's pillow,
And carries off his prize."

and so sparing that life which more than 2,000 years ago was almost prophetically announced by the "divine old man of Cos," Ο βιος βραχυς. Permit me now to make a few remarks in reference to our talented and attentive founder, Dr. Hastings. He would, I am sure, despise fulsome adulation, but to extol the actions of those we value, is surely to be commended. It was Dr. Hastings, who first planted this tree of science which has taken deep root in a cultivated soil, whose branches are extended throughout the remote localities of the British empire—a tree which has stood the rough elements of opposition, and whose leaves only rustle in the breezes of stormy revolution. May the "Tree of science be a tree of peace." Do you ask me "What Dr. Hastings has done?" I reply, "*Si monumentum quæris, circumspice.*" (Cheers.) Do you ask me "Where Dr. Hastings is?" I answer, "At his post, ever desirous of contributing his aid and countenance in support of this Association." Let us, then, prove ourselves the worthy offspring of so valued a sire. Let us, each with all, and all with each, endeavour to promote unity of purpose, and harmony of sentiment, and let us recollect, that although

"Fortes creantur fortibus et bonis,"
Although— "Est in juvencis,
Virtus,"

still there are subjects of far more importance in regulating the machinery of our profession, conveyed in the lines—

"Doctrina sed vim promovet insitam, rectique cultus
pectora roborant."

Dr. Hastings, in returning thanks, said his motto had been "deeds not words;" but still on the present, as on former occasions, he should indeed be dead to sensibility if he did not endeavour to thank the meeting for all the kindness they had shown him, and to assure them that the good opinion they had been pleased to express would cheer him on in his exertions to promote the cause of this great and growing Association. (Cheers.) He confessed that he had high aspirations at the commencement of the work, for the profession then presented itself as a disunited body, combined by no fixed purpose, and having no discipline and no system. What he then proposed was the establishment of an Association whose purpose should be the advancement of medical science in this and all the other nations of the civilized world; but he did not then anticipate what had been accomplised. In sixteen years from that time he beheld an Association which commenced with a few hundred members now amounting to nearly 2,000. But while he mentioned this gratifying fact, he would beg to remind his hearers that they were only in the commencement of the great work in which they were engaged. He would not have them to be satisfied with what had been done, because he conceived the Institution to be, as yet, but in its infancy, that much yet remained to be done to carry out the work of scientific improvement. (Hear, hear.) In the intellectual, the social, and the professional improvement of the medical practitioners of England, they were all interested; and while the legislature might look coldly on their efforts, still they had within themselves the elements of human and scientific advancement. He believed the meeting of the Association in the great and noble and ancient city of Bath, and where, by the way, they had been received in a manner which reflected the highest honour on their resident professional brethren, would be productive of great benefit in England. But the scene of their labours was not confined to this country. Soon after the Association began several of the leading practitioners of Europe united with them, and they were also joined by brethren in America, one of whom was accredited to their meeting that day to assure them of the desire of the American profession to assist them in the great cause. (Cheers.) After glancing at the operations of the Benevolent Fund, Dr. Hastings continued—Our profession is emphatically one which is bound up with the miseries of mankind; and no one can have passed through the various gradations of life without experiencing many admonitions of how soon man may be humbled to the dust, and therefore it becomes us as long as we are in the world to exert ourselves to the utmost for the advancement of science and thus to qualify ourselves to relieve and mitigate the numerous ills to which flesh is heir. Dr. Hastings concluded by proposing the health of Dr. Heygate.

Dr. Heygate returned his cordial thanks for the high compliment which had been paid him in drinking his health. In leaving that splendid city he should entertain a higher opinion than ever of their great Association, and he would only express a hope that their meeting at Worcester might be equally happy and satisfactory under the presidency of the founder, Dr. Hastings.

Dr. Conolly, of Hanwell, proposed the health of Mr. James, of Exeter, and the other Vice-Presidents of the Society.

Mr. James returned thanks.

The President gave the health of the Rev. S. W. Widdrington, Rector of Walcot, which was duly responded to, and acknowledged by that gentleman.

"Success to the Benevolent Fund, and health to Mr. Newnham, its Secretary,"* proposed by Dr. Conolly, of Cheltenham, and acknowledged by Mr. Newnham; "The Bath and Bristol Branch of the Provincial Medical and Surgical Association," proposed by Dr. Hastings, acknowledged by Mr. J. S. Bartrum; and "The health of Dr. Shapter, Mayor of Exeter;" were the succeeding toasts.

Dr. Shapter then gave the health of Dr. Streeten, as Secretary of the Association, and of the Editors of the Journal, coupling the name of Dr. Ranking in the latter capacity.

Dr. Streeten and Dr. Ranking briefly acknowledged the compliment.

Dr. Scholfield, of Doncaster, proposed the health of Dr. Davies, of Bath, the reader of the "Address in Medicine."

* In the course of the evening the President handed Mr. Newnham a donation of £5 to the Benevolent Fund, received from the Ven. Archdeacon Brymer, and a similar sum was presented by Dr. Wood.

The President replied on behalf of Dr. Davies, who had been called to London by the illness of a relative.

Mr. Soden then gave the healths of the Local Committee, by whom the arrangements of the Anniversary had been conducted, which was responded to by Mr. R. F. George.

"Prosperity to the city of Bath," proposed by Dr. Symonds, responded to by Mr. Kitson, was the last toast on the list, after drinking which "God save the Queen" was sung, and the company separated soon after eleven o'clock.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION: NEWTON BRANCH.

PLACE OF MEETING.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Having on a previous occasion ventured through the medium of your very increasingly valuable columns, to raise my humble voice in defence of the change of the place of meeting of the Newton Branch of the Provincial Medical and Surgical Association, to Manchester and Liverpool, I cannot refrain, by your permission, returning my sincere thanks to the immediate promoters of the alteration, as well as cordially to congratulate the members generally on the great scientific advantages involved therein. I, in common with others, ceased from attending these annual reunions, from a feeling that they were more meetings of pleasure than gatherings for great scientific purposes.

I shall now, and from henceforth, gladly rejoin the ranks of my *confrères* with the pleasing assurance before me, that whilst our future meetings will not only be graced by full attendances of the illustrious of our brethren in this county, but (which is of primary moment,) the meetings will be surrounded by everything of professional interest, whether living or dead, in hospital or museum, calculated to render clearer the truths of science, by dispelling the mists by which hypothesis but too often renders obscure the path which leads to the temple of truth. These then, and many more, will be the benefits which must inevitably flow from the change, which will be hailed by none, more than by

Your obedient servant,

CHARLES ANDERTON.

Leigh, near Manchester,
15th August, 1848.

Medical Intelligence.

CONSUMPTION OF OPIUM.

The monthly returns of the Board of Trade, issued on the 10th instant, show that the consumption of opium has largely increased. In the first half of 1846, it was 9,300 lbs.; in that of 1847, it was 27,208 lbs.; and in 1848, it has been 36,985 lbs.—*London Medical Gazette*, August 18th.

APPOINTMENTS.

George Downing Fripp, M.D., has been elected one of the Physicians to the Bristol General Hospital, in the room of Dr. Nicholson, resigned.

John Simon, Esq., has been appointed Professor of Pathology at St. Thomas's Hospital.

Henry Lee, Esq., has been appointed Assistant-Surgeon at King's College Hospital, in the room of Mr. Simon, resigned.

R. Quain, Esq., has been appointed Professor of Clinical Surgery, and G. Viner Ellis, Esq., Junior Professor of Anatomy, in University College, London.

Thomas Morton, Esq., has been appointed Surgeon, and J. E. Erichsen, Esq., Assistant-Surgeon, to University College, London.

John Cooper Forster, Esq., has been appointed Surgeon to the Surrey Dispensary.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, August 11th:—J. Croston; T. Crocker; L. Armstrong; R. Thomason; G. H. Cook; F. C. F. Malden; A. Crompton; J. G. Smith.

Friday, August 14th:—J. S. Garthon; F. Y. Toms; J. J. Cooke; W. C. May; W. T. H. Burrow; E. G. Chapman; T. Michell.

Friday, August 18th:—S. W. Aldred; R. H. Hotham; G. B. Sweeting; R. W. Gillespie; F. G. Thompson; T. G. Copestake; C. B. Bassano; J. Stevenson; W. V. E. Reynolds; W. A. Jacob; B. E. Holwell; D. Asbury; J. H. Gerwood; W. Naismith.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, August 3rd, 1848:—Frederick Foreman Ladd, St. Peters, Isle of Thanet; Charles Underhill, Wolverhampton; John Mills Wills, Brixham, Devon; Thomas Scott, Sherborne; George Charles Sharman, Moseley.

Thursday, August 10th:—George Keer, Parham, Suffolk; Leonard Armstrong, Hexham; Wm. Charles Lake, Teignmouth; Fred. Sopwith, Tonbridge Wells; James Ogden Fletcher, Manchester.

OBITUARY.

Died, June 20th, at Kingston, Jamaica, aged 57, William Arnold, M.D., F.R.S.

July 14th, at Crewkerne, aged 43, Edward Silvester Burnard, Esq., M.R.C.S.

July 29th, of fever, at Roscrea, Henry Powell, M.D.

August 3rd, at Woodford, Essex, aged 70, Thomas Morgan, Esq., Surgeon.

August 4th, at Great Malvern, Alexander Nasmyth, Esq., F.R.C.S., late of London.

TO CORRESPONDENTS.

Communications have been received from B.; Mr. J. Allan; Mr. C. Anderton; Dr. Wardell; C. A.; Mr. Prankerd.

MEDICAL & SURGICAL JOURNAL.

CASES OF FÆCAL ABSCESS.

By John Thurnam, M.D., Medical Superintendent of the Retreat, York.

(Read at the Meetings of the Yorkshire Branch of the Provincial Medical and Surgical Association, at Sheffield and Leeds.)

Attention has, of late years, been directed to abscesses in the abdominal parietes, and particularly in the right iliac fossa, connected with disease of the cæcum or its vermiform appendage, and complicated with fistulous communications with this bowel. Without doing more than allude to the memoirs of various foreign physicians and surgeons, I will merely refer to the papers by Dr. Burne, in the *Medico-Chirurgical Transactions*,* and particularly to a "Report" in the *Dublin Journal of Medical Science*, for May, of the present year, (1847,) in which Dr. Battersby gives an analysis of the various contributions on this subject.†

This form of disease, however, is one which cannot yet be regarded as fully elucidated, and I venture to think that the following cases may have some value in the formation of a more complete history of this formidable class of affections. The cases, indeed, appear to throw some light both on the pathology and the treatment of the disease.

Case I.

FÆCAL ABSCESS, SEATED IN THE SCROTUM; DISCHARGE OF A SMALL PORTION OF BONE; COMPLETE RECOVERY. DEATH FROM OTHER CAUSES: EXAMINATION POST-MORTEM; GREAT ENLARGEMENT AND HERNIA OF THE VERMIFORM APPENDAGE.

A clergyman, aged 56, had for upwards of five years suffered from somewhat impaired health, and exhibited symptoms of mental aberration, on account of a more decided attack of which he was admitted into this establishment, in the spring of 1846. He was of large figure, and stout in proportion, and had been accustomed to eat rather largely of animal food. Soon after admission he suffered from a severe attack of pleuro-pneumonia, but recovered satisfactorily. The mental malady was soon materially relieved, and in the course of the year he more than once appeared convalescent, but again experienced a recurrence of the disorder in a less severe form.

He had formerly been the subject of what was regarded as an incipient inguinal hernia on the right side, for which he had long worn, and continued to wear, a truss. On the 20th of January, 1847, he complained of increased swelling in the situation of the rupture, and I found a tumour, the size of an egg, exactly in the situation of the external abdominal ring, which, after examination, I concluded to be omentum, and made a few efforts at returning it into the abdomen. On the following day a warm bath was ordered, and the taxis was repeated, but still without effect. Later in the day my patient informed me that he had for a few days suffered from a slight uneasy sensation in the iliac region of the same side, and that once during this period he remembered experiencing a sensation of "something giving way" in this situation, but of which he had thought no more. On further examination I found that the tumour was very closely connected with the front of the spermatic cord: it had a pyramidal form, and was evidently seated beneath the spermatic fascia. The patient, who frequently examined the tumour, constantly expressed himself as detecting something like an eel, which glided from beneath his fingers. This I felt myself, and concluded it to consist of the enlarged spermatic cord. There were no symptoms of intestinal obstruction, nor yet of constitutional disturbance. There had been an evacuation from the bowels within twenty-four hours. The tongue was as clean as usual, and the pulse was not accelerated. The tumour, however, had increased in size since the preceding day, and was now the seat of some dull pain, and I determined on treating the case as one of inflammatory swelling. Six leeches were applied to the tumour; three grains of calomel were given at bed-time, and a dose of castor oil in the morning.

The pain was relieved by the leeches; but there was no evacuation from the bowels until about forty hours after taking the calomel, and the patient was hardly convinced that he was not labouring under strangulated hernia, even after two copious evacuations (the first of which was very scybalous,) had been obtained. The tumour now rapidly increased in size, and encroached much on the scrotum. The dull heavy pain also increased. On the fourth day after coming under care, leeches were again applied, and were followed by hot fomentations and poultices, which were subsequently continued. A diet of broth, pudding, tea

* Vols. 20 and 22. On "Perforative Ulceration of the Cæcum," &c. On "Typhlo-Enteritis," &c.
† Vol. 3, p. 515.

and bread was ordered. For a week after this, the tumour increased gradually, but continued free from redness and increase of temperature. Though the patient suffered considerable pain, in consequence of which, and of mental anxiety, his sleep was much interrupted, there continued to be little or no constitutional disturbance. The bowels, though relieved from time to time, were tardy.

On the fourteenth day, the swelling had so much increased as to distend nearly the whole of the right side of the large scrotum. It encroached upon the testicle, and had excited a little serous effusion into the tunica vaginalis. The pain was somewhat more severe. Fifteen leeches were applied, and the same local applications continued; a dose of Dover's powder at bed time, and a saline aperient draught in the morning, were also given.

Considerable relief, as regards the pain, was now obtained, but the tumour continued to enlarge. The patient obtained a good night's rest from the Dover's powder, which, after a night or two, was exchanged for a pill, containing three quarters of a grain of acetate of morphia with extract of henbane. This pill he continued to take with much advantage for several weeks. On reviewing the history and progress of the case, I now concluded that, though an unusual situation for such an affection, the case would prove to be one of fæcal abscess.

On the twentieth day the tumour was nearly as large as the two fists, and something like softening was detected at the lower and anterior part. The pain had assumed a more severe, heavy, and burning character; and on questioning the patient, I found that a day or two before he had experienced a distinct rigor. The bowels continued to be torpid, and saline aperients and enemata were administered, not without due effect.

On the twenty-fourth day the pain had increased much in severity; and in the situation before adverted to, for the extent of about a five-shilling piece, fluctuation of an indistinct kind and rather deep-seated, was detected. There was no cutaneous discolouration. A seton-lancet was introduced, and exit given to less than half an ounce of a dirty olive-coloured matter, of a semi-purulent character, and having a most abominable and worse than feculent odour. This was mixed with, and followed by, a few bubbles of gas. A pledget of lint was introduced into the wound, and the poultice was continued. Great relief was obtained by this proceeding; about half an ounce of matter was discharged daily, evidently from a point considerably below the surface; and this gradually assumed a less offensive and more healthy character, though it was still mingled with bubbles of air. The tumour diminished very slowly in size and continued to be the seat of a dull heavy pain. Though somewhat reduced in strength, the general health was scarcely at all affected. A little fish and meat, with two glasses of wine, were now added to his diet; and the decoction of bark, with sulphuric acid, was also given. Constipation of the bowels was obviated by occasional doses of castor oil. At the end of about a week it was found that whilst the discharge of matter had much diminished, a second little abscess was forming about an inch below the former one, and in this situation there was much tenderness and some discolouration. The general mass of the tumour was but slightly reduced in size. On the thirty-fourth day this second abscess was opened, and about three drachms of rather sanious pus, much less offensive than that from the former one, were discharged.

During the month which followed, the suppuration, which had never been abundant, by degrees almost entirely subsided; the opening which had been first made healed; but the tumour did not diminish in the way which might have been expected. Towards the end of this period, the sinus left by the last abscess assumed a rather irritable condition; there was considerable tenderness on pressure, and the surrounding integuments were of a dusky red colour. The bowels continued torpid, and required frequent aperients.

On the fifty-ninth day, the sinus was laid open to the depth of about half an inch. After this had been done the patient complained of much pricking pain, and upon removing the lint with which the wound had been dressed, about four hours afterwards, a small piece of hard bone was found to have been discharged. This little bit of bone was of a triangular shape, with sharp angles, and did not measure more than a quarter of an inch in any direction. It was probably a portion of a bone from a mutton chop, which had been swallowed, and had escaped digestion.

After this there was no more pain, the suppuration entirely subsided, the sinus immediately healed, the tumour as rapidly diminished, and at the end of ten days from the discharge of the piece of bone, viz., on the seventh day of the illness, (the end of April,) was entirely absorbed. For a few weeks there was a little relaxation of the integuments of the groin and scrotum, but this soon disappeared, and at the present time (June 4th, 1847,) his general health is in every respect as good as it was before this attack of indisposition.

I shall not make many observations on this case, the pathology of which appears sufficiently obvious; I will merely state that I conclude the mucous membrane of the cæcum was predisposed to disease, by the habitual constipation of which the patient was the subject; that ulceration of the mucous membrane of this bowel, or of its vermiform appendage, was thus produced; that this had terminated in perforation of the bowel, and in the escape of some of its contents into the surrounding cellular tissue; and that these latter had, in their turn, given rise to the inflammation and abscess which were the subject of treatment.

The result must be regarded as in all respects most satisfactory. The progress of the case was tedious, but the recovery was complete. The case, I submit, confirms the importance of opening the abscess as early as fluctuation can be distinguished, and thus preventing the occurrence of sloughing, in which so many cases of fœcal abscess find a fatal termination.*

* A case which I had the opportunity of observing at the Westminster Hospital, in 1835, illustrates well the

The foregoing case and observations were read at the meeting of the Yorkshire branch of the Provincial Medical and Surgical Association, held at Sheffield, June 10th, 1847. The patient was then in usual health, but, from causes altogether unconnected with the disease now described, his death occured within a month from that date,—viz., on July 8th.

Upon *inspection* of the abdomen, the intestines generally were found unusually large and distended with flatus. There was a patch of opacity and thickening on the peritoneal covering of the cæcum; its mucous membrane was rather thickened, and of a reddish brown colour, particularly around the enlarged opening of the vermiform appendage. This minute bowel was more than twice the usual length, and otherwise at least three times the ordinary size. Externally it was grey and mottled, and its tunics generally much thickened. The meso-appendix was much enlarged, thickened, and contained much fat. The three lower fourths of the whole appendage were contained in the form of a minute hernia, in the abdominal canal; its apex, which was opaque, contracted and thickened, was firmly adherent to the bottom of the canal, by an elongated firm band of adventitious serous tissue, of glistening whiteness; the omentum did not extend into the hpyogastric region, and there was nothing to indicate that any other portion of the intestinal canal had ever been the subject of rupture.*

It will be observed that the appearances after death correspond remarkably with the general conclusions, as to the character of the case, which were formed during life. It will now, moreover, be seen that the symptoms are still more remarkably explained by the precise condition and situation of the vermiform appendage. A hernia of this minute bowel, if we may so term it, has only once before, so far as I am aware, been described,† and was, perhaps, hardly to have been anticipated during life.

The feeling which the patient experienced on manipulation of the tumour, and which he compared to that of an eel gliding through his fingers, was no doubt really attributable to movements in the abdominal canal of the vermiform appendage itself. This symptom may aid probably in the future diagnosis of such a case. I think it highly probable that the use of the truss which the patient had worn for several years was positively injurious, and I can hardly avoid the inference that it had strongly predisposed to, if it had not actually excited, that disease of the vermiform appendage which, under the presence of such an extraneous body as a piece of bone, ultimately terminated in perforation and abscess. In conclusion I may remark, that the complete recovery, after so important a lesion of the intestinal canal, as ulceration and perforation, is well illustrated by the appearances observed on *post-mortem* examination in this case.

Examples of fæcal abscess and fistula, connected with malignant disease of the large intestines, have not, I think, been very frequently recorded, and I am therefore glad to take this opportunity of appending the particulars of the following case:—

Case II.

FÆCAL ABSCESS, OPENING BELOW THE UMBILICUS; DEATH. MEDULLARY FUNGUS AND ULCERATION OF TRANSVERSE ARCH OF COLON, WITH FISTULOUS OPENINGS.

A respectable female, unmarried, aged 68, who laboured under a strong hereditary predisposition to insanity, and had been during more than half her life, an inmate of the Retreat. The case had commenced with maniacal excitement, which alternated with melancholia. At the end of ten years the disorder lapsed into imbecility, which lasted through life. About the same period she sustained a severe attack of apoplexy, and was subsequently subject to slight fits of epilepsy. When she came under my care, in the autumn of 1838, she was distinguished by a pale, wax-like complexion, flabby muscles, and feeble gait; but otherwise had tolerable health.

On the 11th of January, 1839, she was paler than usual, and was unusually fretful. On examination I detected a fulness on the right side of the abdomen, with much tenderness on pressure. The tongue was moist and white; the bowels confined, and the stools dark and offensive; the urine thick, scanty, and decidedly acid; the appetite but little affected. A dose of calomel and rhubarb, followed by a saline aperient, was given; and on the following day, twelve leeches were applied to the swollen part of the abdomen, which was afterwards covered with a warm linseed poultice.

On the 14th, the tenderness and fulness being only partially relieved, and the character of the evacuations unaltered, leeches were again applied, and three grains of mercury with chalk, and five grains of nitre, were given three times a day.

On the 15th, the fullness was considerably diminished, and she did not shrink so much on pressure; deep-seated hardness was, however, still to be detected. The pulse was 96, rather sharp and full. The improvement was now rapid; the local symptoms gradually subsided, but the evacuations continued dark and offensive, and the urine very acid.

On the 18th she left her bed; a few doses of bicarbonate of potass, and blue pill with colocynth, were

mischievous results of a too expectant surgery in these cases.—See "Med. Chir. Review," 1836, vol. xxiv., p. 567. A very similar and equally instructive case is reported by Mr. Ormerod, in his "Clinical Collections and Observations in Surgery," 1846, p. 189.

* A preparation of the diseased part is in my possession

† By Tarantelli, in Omodei's "Annals," 1835, quoted by South, in Chelius' "Surgery," 1847, vol. ii., p. 3., cases of hernia of the vermiform appendage, in connection with hernia of the cæcum, are much more common. See two cases by M. Lausberg, *Provincial Medical and Surgical Journal*, 1847, p. 529.

ordered, and under this treatment the evacuations assumed a more healthy character.

On the 24th, though more feeble than before the attack, she appeared convalescent, and all remedies were omitted.

She had remained apparently well for about a fortnight, when, on the 6th of February, a circumscribed tumour, the size of an orange, was detected in the abdominal parietes, immediately below the umbilicus. This tumour was firm, afforded a dull sound on percussion, and could be handled without occasioning pain. The skin was cool; the tongue moist and white; the appetite was impaired; the evacuations pale and watery; the pulse 90, small and feeble; there was little constitutional disturbance. A saline aperient draught was given, which acted freely on the bowels; and on the following day six leeches were applied to the tumour, and a few doses of calomel and antimonial powder were administered.

The tumour increased in size, so that on the 12th of February it had attained twice its former bulk. At this time it presented a slight blush of redness; and, upon examination, an obscure sense of fluctuation, combined with an emphysematous crepitation, was communicated to the fingers. The tongue was dry, and covered with a yellow fur; the bowels free; the pulse 90 to 100, rather full and soft; there was slight nocturnal perspiration, but no sickness nor rigor. I had now no hesitation in coming to the conclusion that the case was one of "fæcal abscess, communicating with the large intestine, and most probably containing gas." I had ventured a conjecture that this was the character of the case six days earlier. Poultices, which had been applied for the two preceding days, were continued.

On the following day, (the 13th,) the signs of suppuration and the peculiar sense of crepitation having all increased, and the tumour exhibiting a livid discoloration, it was punctured with a lancet. Exit was thus given to about an ounce and a half of a dark purulent matter, having a highly offensive and strong fæcal odour, and having numerous bubbles of gas mixed with it. The cavity of the abscess was found to have a firm tendinous-like base, but no communication with the intestine could be detected with the probe. A diet of beef-tea, with a fair supply of wine, was directed.

For three days after opening the abscess she bore up pretty well, but the pulse was 100, and feeble, and the tongue brown and dry. The abscess discharged a dark matter, mixed with bubbles of air, so offensive that, notwithstanding all precautions, the room was almost intolerable. There was little or no evacuation from the bowels, and she was troubled with occasional borborygmi, the sound of which appeared to be connected with the open abscess. The quantity of wine was increased.

On the 16th an enema was administered, which produced an evacuation, mixed with many small scybala. The abscess assumed more of a gangrenous character; increased prostration of strength was evident, and a fatal termination was looked for daily. Under assiduous nursing, and the administration of animal jelly and wine, (of the latter of which she took a bottle daily,) she rallied, and on the 19th the pulse had sunk to 90, was fuller, and stronger; the tongue was moist, and nearly clean, and the evacuations more copious. A few distinct coagula of blood, and a small portion of organized substance, containing some white granules, resembling diseased mucous membrane, (and probably containing encephaloid,) were detected in the evacuations.

The discharge of purulent matter now almost ceased, and a slough began to separate. Under this process the vital powers again appeared to give way, and the ankles became œdematous; the urine was acid, but not albuminous. The surface of the large sore, produced by the separation of the slough, had a livid and very unhealthy appearance.

On the 25th, upon cutting away a portion of the slough, some purulent matter, mixed with many bubbles of gas, again escaped.

On the last day of February the slough had entirely separated, the surface of the sore had put on a healthy character, and was being rapidly filled up with granulations. Though the pulse remained small and feeble, the tongue was moist and clean, and the evacuations from the bowels assumed a more healthy character. The urine was thick and scanty. The quantity of wine was diminished, and she was ordered a mutton chop.

The cavity of the abscess now gradually filled up, leaving only a small fistulous opening in the centre, of a depressed and puckered cicatrix. By the end of March all discharge from this fistula had ceased, and it closed completely. Though continuing feeble, she was at this time able to return pretty much to her ordinary mode of living; this, however, was of short continuance.

On the 7th of April the cicatrix gave way, and allowed the escape of some thin offensive purulent matter, mixed with a few bubbles of gas. From this period a few drops only of pus were discharged daily, until her death, two months later. Pallor and sallowness of the complexion increased, and emaciation proceeded rapidly. There were free evacuations from the bowels and bladder. Early in June it was observed that there was fulness and dulness on percussion, in the epigastric region. Œdema commencing in the ankles, extended up the right leg to the thigh; the emaciation became extreme; the tongue was brown and dry, and she took nothing but wine in small quantities. Respiration subsequently became short and impeded. During two days the secretion of urine was suppressed, and after lying in a moribund state for at least thirty hours, she died June the 12th.

Post-mortem inspection sixteen hours after death:—* The diaphragm was pushed considerably upwards, by the enlarged abdominal viscera; the heart was small, and weighed only six ounces and a half; the liver was much enlarged, and crowded throughout with large tubera of medullary sarcoma. These masses were very soft and pulpy, and of a yellowish-grey colour, mottled with a chocolate-red. The hepatic tissue was much

* The morbid appearances in the brain are omitted, as irrelevant to this paper.

diminished in bulk, very pale and soft; the gall-bladder was small, and contained a little dark green bile; the spleen was firm, and of a livid purple colour; the mucous membrane of the stomach presented a not very slight thickening over a limited space, about the middle of the large curvature. The small intestine was healthy, except that one convolution was twisted, and had a very red colour; and that another convolution had gained an adhesion to the mass of disease in the large intestines about to be described. The omentum contained considerable fat, and was connected with the abdominal walls, in the situation of the umbilicus, by delicate bands of serous tissue; immediately below, and forming one mass with the omentum, were the displaced cæcum and transverse arch of the colon. Upon laying open the large intestine, the principal lesion was found seated in the middle of the transverse arch. In this situation, to the extent of two or three inches, the muscular tunic of the bowel was the seat of scirrhous degeneration and hypertrophy. The mucous membrane, to the same extent, was replaced by a growth of soft cancer, which in some places was softened, broken down, and ulcerated. This fungous growth blocked up the intestine in such a way that the little finger could barely be passed through it. At the bottom of the ulcerated surface there was a small opening, by which a probe could be passed through a mass of sloughy and suppurating tissues in the centre of the adhesions, and at the bottom of the contracted cavity of the abscess, and so through the external fistulous opening. The large intestine above the seat of disease was somewhat dilated, whilst below it was less capacious and thinner than usual. In the upper and left part of the cæcum were two small orifices, about half an inch apart, with elevated thickened borders, through each of which a probe could also be passed into the external fistulous opening, which it will be thus seen communicated with the large intestine at three points. The mucous membrane around the fistulous orifices in the cæcum was rather thick and red, but otherwise the cæcum and vermiform appendage were healthy. The kidneys were pale and soft, and their external surface slightly granular, portions being raised and torn off with the fibrous tunic.

Cases of fæcal abscess and fistula originating in malignant disease of the intestinal canal, have seldom been recorded, and I am not myself able to quote any previous example of this kind.

Mr. Teale, in his valuable article on "Intestinal Fistula," in the second volume of the *Cyclopædia of Practical Surgery*, makes no mention of malignant disease, as a cause of fæcal abscess or fistula.

The case now described seems to have an interest in connection both with fæcal abscess generally, and with such abscesses dependant upon malignant disease in particular. As regards the diagnosis of fæcal abscess, it will have been seen that the case was recognized at a period sufficiently early for all the purposes of treatment. Although, on the retrospect, it may perhaps be thought that there were grounds for the opinion, that the disease was connected with a malignant growth in the bowel, no such suspicion was entertained during life. The encephaloid tubera in the liver were, doubtless, developed subsequently to the disease in the colon, and were, most probably, the cause of that enlargement in the epigastric region, which was observed at a late period in the history of the case.

The best description, in a few words, of fæcal abscess, is, I think, that by Mr. Teale, in the article already referred to. In this article—almost the first in any systematic work in our own language, in which the disease has been described—under the head "Intestinal Fistula from Abscess," Mr. Teale has the following remarks:—

"Various hard substances introduced into the intestines are capable of exciting irritation in the coats of the bowel, and of giving rise to abscess. The ulcerative process, whereby the matter gradually makes its way towards the surface, is usually preceded and accompanied by a process of adhesion. The peritoneal coat of the intestine, before being opened by ulceration, is thus agglutinated to the abdominal walls, and effusion of feculent matter into the bag of the peritoneum is prevented. These abscesses are generally indolent in their course. They are usually preceded by a dull fixed pain in some part of the abdomen, attacks of colic, and various disturbed conditions of the digestive functions. The seat of pain becomes firm and unyielding; at length a well-defined tumour may be felt; the integuments assume a dull red colour; obscure fluctuation is perceptible; and the abscess, opening upon the surface of the body, discharges pus, feculent matter, and occasionally the extraneous body, which originally excited the mischief. In this manner fæcal fistula is ultimately established."

The two cases which I have narrated, tend, I would suggest, to shew, that the characteristics of abscesses of this kind are capable of being laid down, in some respects, with more precision. In the first place, the presence of gaseous matters in the contents of the abscess, and the consequent sense of crepitation communicated to the fingers before the abscess is opened, and the presence of bubbles of air in the purulent and feculent matters which are afterwards discharged, seem to me most important features in the symptoms. The tendency, too, to gangrene in the neighbourhood of the abscess, and the consequent necessity for the early incision of the suppurating tumour, appear to call for our especial notice. When the abscess is dependent, as in my second case, upon malignant disease in the bowel, the presence in the evacuations of organized matter, containing cancer-cells, may be expected.

FACTS RELATIVE TO EPIDEMIC CHOLERA, DETAILED FROM PERSONAL OBSERVATION OF THE DISEASE, AT PLYMOUTH, IN 1832.

By Edward Blackmore, M.D., Bath.

As malignant cholera appears to be making, with steady steps, towards this country, I beg leave to communicate to the Association, in sequence of the paper by Dr. Black, in January of the present year, and that read by Dr. Tunstall at the late Anniversary Meeting, some observations which I had an opportunity of making at Plymouth, in the course of my private practice, and in that of the Public Dispensary, and of the largest of the Cholera Hospitals, of which I held the charge in rotation with some of my professional brethren in that town. I shall confine my present paper to a brief statement of the general facts, having published in the *London Medical Gazette*, in the autumn of 1832, a more particular account of the invasion and progress of the disease, as it appeared at Plymouth.

During the previous winter and spring, many cases of sudden severe vomiting, and purging of bilious, mucous, and serous fluids, with cramps of the legs, came under my notice, and excited alarm as the apparent harbingers of "the cholera;" they were, however, plainly distinguishable from the malignant epidemic disease. The extreme and rapid collapse of the vital powers, the corpse-like aspect of the countenance, the peculiar coldness of the skin, the *serous* character of the ejected matters, the inadequacy of the vomiting and purging to the danger of the case, the excessive abdominal and pulmonary congestion of undecarbonized blood which was revealed on anatomical inspection, sufficiently characterized the epidemic as a novel and mysterious malady.

As to its *remote causes*, we had abundant evidence of the powerful influence, in favouring the outburst of the disease, of unripe and acid, and over-ripe and decayed fruits; of indigestible meats, particularly fish; of debauchery; of cold, and fatigue, and fasting; and of *mental depression* by grief or terror. Of this latter cause a memorable instance occurred, of two estimable and zealous parochial clergymen,—one, being utterly fearless, sought out and sedulously attended all the cases within his reach, from early morning to late at night; the other, who was in weak health, and fearfully apprehensive, secluded himself within his house or high-walled shrubbery. The former passed his ordeal scatheless; the latter got the disease and died asphyxiated in a few hours. Mental confidence, however, in those who attended the sick, was not an infallible preservative:—A surgeon, who was associated with me in the duties of the Cholera Hospital, scoffed at the idea of contagion, and in our rounds he would sit on the sick beds in spite of all remonstrances. On one occasion he was embraced by a patient, got the disease the same evening, and died in six hours!

Without entering into the question of the *contagious origin* of the disease, in the strict and absolute sense, I would state that many instances convinced me of the *dangerous influence of much intercourse with the sick*. I suffered myself on those occasions when my professional attentions were more than usually intimate—when, in fact, I was obliged to be the nurse as well as the physician.

The powerful morbific influence of certain localities, as of low, ill-ventilated, damp, water-side situations, was also very evident; and of the co-existence of a peculiar electric and barometric state of the atmosphere there was no doubt. My friend Sir William Snow Harris, in a note written to me a few months after the epidemic, informed me, that during the whole time of its prevalence at Plymouth, the barometer was *extraordinarily high*.

Regarding the *treatment*, my experience convinced me that in all cases in the early period, and also in every stage when the case wore the malignant aspect, and the peculiar epidemic characters, *opium* and *astringents* were useless, and *possibly injurious*; but in proportion as the case resembled the ordinary sporadic English cholera, those means were more suitable. We found *stimulants* also, given internally,—such as the oils of cajeput, cinnamon, and cloves, and brandy and salt, utterly useless for relieving the collapse of the vital powers, and I believe that in many cases they did harm; the vaunted salt-water treatment, when used without due limitation, was followed by intestinal hæmorrhage. I believe that the *internal* use of the *hydro-carbons*,—as Barbadoes tar, naphtha, &c., would equally disappoint the practitioner. If we may venture to define the *elements of the malignity of the disease*, from simply surveying the phenomena in the living and the dead, we would say that the extreme congestion of undecarbonized blood in the vital organs, is the grand component, which condition has been observed also in most other epidemic diseases of a malignant form; and this view of the pathology clearly contra-indicates the use of all *hydro-carbons*. The deficiency of carbonic acid in the expired air, is from the interruption of the vital functions of the lungs, not from a want of carbon in the blood, on which theory tar seems to have been recommended.

Observation demonstrated the great importance of those medicines which act on the excretory functions,—such as *mustard* or salt, given as an emetic; *calomel* in large doses, (one scruple,) combined with a large dose (say one drachm,) of the *fixed alkaline carbonates*, (*pure calomel induced serious remote consequences*;) in some cases I preferred, and took myself, with advantage, small doses of the *volatile alkali*, with the black oxyde of mercury, in arrowroot. These means were also administered by the *rectum*, with

marked advantage. In treating sporadic English cholera, for many years previous to the epidemic, I had observed the good effect of a *scruple* dose of *calomel*, combined with half-a-drachm of *magnesia*; and in cases wherein these medicines were used, it was scarcely *ever* necessary to give laudanum or opium in any form; but in the epidemic cases I preferred the *alkalies* to magnesia. We found decided advantage from using Dr. Stevens's *compound saline powder*, of carbonate of soda, muriate of soda, and *chlorate of potass*; the pulse became developed, and the black state was often relieved after its use. *Small bleedings* were, in many cases, of great benefit; many severe "*asphyxiated* cases," in the second and third weeks of the epidemic, were apparently saved by such venesections. *The first of the successful cases at Plymouth was bled*; the previous fatal cases, so far as I knew them to have had any medical care, were treated according to the instructions issued by the Central Board of Health, at Whitehall. *Saline injections into the veins* were tried in many cases; in few did they realize the expectations of the profession. The *acetate of lead*, given by the rectum, as well as by the stomach, did good in the diarrhœa of the protracted cases. I learned from some brother-practitioner, that the *severe thirst* was best relieved by *cold water*, and by *lime-water with milk*. To myself it appears that the thirst might be better assuaged by giving them cold fluids immediately after a copious draught of *warm* or *hot* chicken-broth, of which *Sydenham* speaks so highly.

There was abundant evidence of the good of various *external means*:—as, *frictions* of the limbs and trunk with dry and warm flannels, sometimes sprinkling on them the flour of mustard or hot salt, embrocations of turpentine, cajeput, ammonia, and other stimulants, and hot linseed and mustard cataplasms on the abdomen. Caution indeed is necessary in the use of friction and stimulants, for in some cases the violent use of them favours subsequent gangrene of the skin. *Swathing* the abdomen and the lower limbs with flannel bandages evidently relieved the cramps. *Heat*, by means of hot *air*, and various heated solid substances, *rather than heat with moisture*, was clearly beneficial. I would suggest, however, in conformity with a remark by Dr. Black, that in every mode of employing stimulant drugs, and even *heat*, we should observe the principle of the treatment of burns and frost-bitten parts, and *take great care not to induce a sudden or violent change in the vital action* of the body, or any part of it; and as soon as the vital power begins to return, the stimulus should be diminished or withdrawn.

The various statistical returns of the proportion of deaths to the sick cases, in different parts of the United Kingdom, shows a singular *equality* in the relative mortality, although the same therapeutic means could not have been universally adopted; yet I venture to assume that other practitioners saw what occurred to my own observation, that in individual cases certain means were so quickly attended by a marked improvement, as fairly to entitle those means to our preference; and also that my experience convinces me that Dr. Black takes too hopeless a view of *asphyxiated* cases.

As to the *prophylaxis* of the disease, I had strong evidence of the salutary effect of observing regular hours for *sleep* and *meals*;—of using a moderately generous diet of animal food and wine, with a smaller proportion than usual of fluids;—of *warm clothing*, particularly flannel around the abdomen, the celebrated "*anti-cholera belt*," and putting on warm silk, or fine worsted, stockings, towards evening;—of *a moral courage*; and of the especial importance of the *due regulation of the functions of the bowels and of the liver*, for which regulation a daily inspection of the stools was absolutely necessary. The slightest constipation, the least degree of *torpor of the liver*, had a manifestly bad effect. In short, whatever maintained the best state of the general health, and gave mental confidence and cheerfulness, was found to be the best preservative. I was much impressed by observing, that on the Sunday night the new cases were nearly a *third more* than those which occurred in any other night of the week! The fact seemed explicable only from the alarming influence of the style of sermons which the awful events suggested, the depressing effect of the thronging of a multitude in a confined space, and possibly also, of the more immoderate suppers, and the later hours which the many laborious classes of the population indulged in on the evening of the day of rest.

I am happy to have it in my power to affix to this very imperfect paper an extract from a letter, written to me in August, 1832, by my late revered and beloved friend, Dr. Abercrombie, of Edinburgh, relative to the cholera:—"Our chief object of attention for many months past, has been this new and fearful epidemic, which has descended upon us like a judgment from the hand of the Almighty. It has been comparatively limited in its extent here, but very fatal in proportion to the number affected; and after seven months experience, I cannot say we have made any progress in our knowledge of the disease or its treatment. We have had more success, I think, in checking its progress, by most extensive measures for feeding the poor and cleansing their houses; and by an extensive quarantine system—removing into houses appropriated for this purpose, persons who had been in immediate connection with the sick. We have no doubt of the disease being communicable by personal contagion in particular cases, though it also evidently spreads in another manner, by an epidemic influence which is altogether beyond our researches."

ON THE ADMINISTRATION OF DIURETICS IN SOME CASES OF DROPSICAL EFFUSION.

By Jonathan Toogood, M.D., Torquay.

It is admitted by the most experienced practitioners, that all those medicines which are known under the denomination of diuretics, are generally uncertain in their operation, nor has it been explained why the same class of medicine succeeds in one case, and fails in another, in which no appreciable difference in the condition of the patient can be ascertained; for although the late researches have led to a more accurate discrimination into the different states of the urine, and consequently to a more scientific method of treating these diseases, we often have the mortification of finding, that, however skilful our treatment may be, or however appropriate our remedies to each individual case, our practice is unsuccessful. It is not my intention to discuss the various forms of dropsy which we meet with in practice, or the effects of remedies generally, but it may be useful to relate two or three cases which resisted the ordinary treatment, but subsequently yielded to various remedies, although no different cause of disease, or indeed unsoundness of any of the viscera, could be detected, by the most accurate examination.

William Jennings, aged 46, contracted an ague in October, which continued during the winter, and in the following spring I found him still with a tertian ague, and generally anasarcous. The effusion was so great, that it was impossible, by the most careful examination, to ascertain accurately the condition of the different viscera, but it was very evident that there was a considerable accumulation of fluid in the cavity of the abdomen. My first object was to cure his ague, which was effected by bark, the arsenical solution of Fowler having failed; after which various purgatives and diuretics were directed, and steadily persevered in, without affording the least relief. He daily became worse, and the whole cellular tissue was so enormously loaded, that he was unable to wear his usual clothes. As every variety of diuretic had been repeatedly and ineffectually tried, I despaired of his recovery, when it occurred to me that the late Dr. Parry, of Bath, had recommended the fresh squill in a variety of cases, which he stated to have been successful in his hands. Six grains of fresh squill, in infusion of gentian, three times a day, considerably increased the flow of urine in four days, and by gradually augmenting the dose, he was emptied, and recovered perfectly.

This case occurred as far back as the year 1811, and as the patient lived in my own neighbourhood, I did not lose sight of him. He continued free from any return, and died many years afterwards of another disease.

I may add that this medicine was given by Dr. Parry, in some cases, to the extent of thirty and forty grains a day, and that he often prescribed it in asthma, combined with almond emulsion, occasionally adding to each dose a few grains of powdered myrrh, with the best effect.

Mr. Harris, aged 28, became rather suddenly affected with anasarca, without any known cause. It began in the lower limbs, but soon became general, and increased to such an extent, that the whole trunk, arms, head, and face, were involved in the swelling. I observed in this, as in the former case, that the impression of his hand and fingers remained for a considerable time wherever he supported his head. All kinds of purgatives, diuretics, and every variety of treatment which was suggested, failed. The only medicine which produced any effect on the kidneys was the tincture of squills, of which he took sixty drops three times a day. This afforded a partial relief only, and never increased the water beyond a given point. An unprofessional person recommended the following plan, the effect of which I carefully watched:—

A teaspoonful of finely-powdered broom-seed was given every other morning in a wine-glassful of sherry, and one ounce and a half of Florence oil, an hour afterwards. After the fourth dose, the urine was much increased in quantity, and by continuing it for another week, he was completely evacuated. He remained well for six months, after which time he left my neighbourhood, but I believe he did not eventually recover.

I have, however, repeatedly tried this plan since, but have been disappointed. The last case which I shall relate, will, I think, prove an interesting one:—

Miss O———, aged 50, had enjoyed good health, with the exception of an habitual cough, which was considered too trifling to require treatment at any time. She was attacked in the spring of 1847 with a bilious complaint, for which she was subjected to active treatment, and took, as I understood, repeated doses of calomel, after which she caught cold. On my first visit I found her complaining of great debility, with loss of appetite, but all the secretions were natural. Shortly after this her feet became anasarcous, and notwithstanding the regular exhibition of diuretic medicines, this state increased until it spread to the abdomen, arms, and face. The secretion of urine became very scanty. No relief was obtained from the diligent use of various diuretics, especially squills, and digitalis, which was pushed to the full extent of safety, and given in infusion, that form which appears to be the most efficacious in inflammatory dropsy, and assisted by the warm bath, but her state became worse daily. The urine coagulated much more and more firmly than is common in dropsical cases, and the specific gravity was greater than on these occasions, being 1018. This excess of coagulum and specific gravity indicated a lurking inflammation, and as no organic derangement could be discovered, granular disease of the kidney was suspected. In this stage of the disease, a consultation with Dr. Blackall, a great authority in such cases, was held, who recommended that the capsules of copaiba should be taken two or three times a-day, that the cream-of-tartar liquor should be

drank very freely, and that she should use the vapour bath, beginning at 100°, and increasing it to 110° and upwards, if it could be borne. A moderate diet was prescribed, with two or three glasses of hock daily. She rapidly improved under this judicious plan of treatment, and has continued free from any return of disease up to the present time. The urine was frequently tested during the progress of her recovery, and the coagulation gradually ceased, and ultimately disappeared entirely.

The publication of these cases will, perhaps, class me with the "Eclectic Practitioners," described in the *Edinburgh Monthly Journal*, "as men who have no doctrine and no general principles, who gather together ready-made formulæ and isolated cases without any kind of discernment;" and who are thus spoken of by Professor Cruveilhier, in his address to the Anatomical Society, 1845:—"The true eclectic works without conviction, without principle, without idea. He is continually enlarging his circle, in order to enclose within it facts of the most contradictory nature; they sacrifice in every sort to every God, and create a kind of scientific pantheism, not less fatal to true science, than pantheism, properly so called, is to true religion."

The great aim and object of medical science is to cure disease, and I, for one, am always glad to avail myself of the experience of practical men, in obscure and difficult cases, however lightly they may be esteemed by some; I do not, therefore, subscribe to this sentiment.

Torquay, July 17, 1848.

SPASMA GLOTTIDIS: REPLY TO DR. WARDELL.

By T. Ogier Ward, M.D., Kensington.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir

In this rejoinder to Dr. Wardell's reply to my observations upon certain cases of so-called spasma glottidis, reported by himself and others, it is not my intention to re-open the question of the real nature of those cases, except to show that he has overlooked some points of importance in those of Messrs. Gorringe and Alford. The facts are before the profession; but if we have failed to convince each other that the interpretation we have mutually given of them is the correct one, we are still less likely to establish our opinions in the minds of others who take comparatively very little interest in them, and who would, most probably, while reading your periodical, skip the discussion as a bygone affair. In reference, however, to my own case, the matter is different, *(mea res agitur,)* and therefore, I trust I may be allowed to defend the accuracy of my statements, and the propriety of the treatment, as being consistent with the view I took of the nature of the disease.

First, then, I emphatically deny that my patient was an hysterical subject at all, though being a female, Dr. Wardell thinks that is a sufficient reason for assuming this to be "precisely one of the cases in which we observe anomalous hysteric spasmodic attacks;" at least, this is all the meaning I can extract from the sentence as it stands. The next point objected to is, that the suddenness of the seizure is inconsistent with the occurrence of inflammation; yet the patient had been ill twenty-four hours with influenza, which was so commonly attended with laryngitis, that Dr. Wardell's friend, Dr. Smith, had three cases under his care about this time, besides the instance of the boy quoted by Dr. Wardell, of which we shall speak presently. Dr. Wardell objects also to my not having found any redness of the throat, as a proof that the disease must have been spasmodic, yet he quotes with approval Mr. Alford's case of "spasma glottidis," as purely nervous, in which this redness did exist. But, in fact, in my case, the larynx was so evidently the seat of the affection, that, knowing it to be invisible to inspection, and having frequently observed that in croup and other inflammatory diseases of the larynx, the widely opening of the mouth, and the protrusion of the tongue, as well as the act of swallowing, produce an increase of the pain and dyspnœa, by putting the inflamed parts on the stretch, I was unwilling to increase the sufferings of the patient by a minute inspection of her throat. To the next charge of believing that the alum was the cause of the speedy relief, I must plead guilty, even though Dr. Wardell be ignorant of its use in such cases; but that he may not longer be so, I beg to refer him to a memoir upon this application of alum, appended to his work on "Diphtherite," by M. Bretonneau, from whence I borrowed the idea, thinking that if it would prevent the effusion of lymph *a fortiori*, it would that of serum. I must also confess my ignorance of the benefits to be derived from the rather heroic remedy, recommended by Dr. Wardell, of "rotating my finger freely in the throat" of a patient suffering from agonizing pain in the larynx; but that even had I been aware of such a practice, except in the case of a foreign body been lodged there, I should have hesitated to employ it, and I think that before Dr. Wardell objected to my supineness in this respect, he should have given us the reasons for not having done so in his own cases, which he believed to be purely nervous, and therefore the best adapted for such a mode of treatment. I may be wrong, but I suspect that this "rotating the finger freely in the throat" is an after thought, borrowed either from Mr. Alford, *who used it without benefit*, or from Dr. Laycock's case of combined epilepsy and hysteria, in which the patient was comatose at the time of the operation. Be it so or not, I have very little doubt that if Dr. Wardell, or any other medical man in private practice, makes a rule of "rotating his finger freely in the throats" of his patients, when suffering from laryngeal irritation, or even nervous spasm, they will think the

operation, if not the doctor, partakes too much of the *fortiter in re* to request a repetition of the process.

I do not know why Dr. Wardell should suppose that I need his instructions respecting the effects of vomiting in removing obstructions in the larynx, whether arising from spasm of the muscles, or from mechanical causes, inasmuch as I commenced my treatment by giving my patient two grains of tartarized antimony; and it was not till I was afraid to wait any longer for the action of the medicine, that I applied the alum to the amount of nine or ten grains, not *nineteen* as it is misprinted.

I forbear to comment on the other particulars of this case, for the reason stated at the outset of this paper; but I cannot pass over that Dr. Wardell, (I presume inadvertently, as his whole paper bears marks of having been written in haste,) has, in the space of four lines, p. 314, col. 2, lines 13-16 from the bottom, changed my meaning twice, viz., by asserting that the *cure*, not "the *relief* from immediate danger" was effected in half an hour, and that "I failed to recognize my patient at my *next visit*," instead of "the next day at my visit," a difference in space of time, sufficient to produce extraordinary changes in the appearance of a patient in any acute disease, to say nothing of threatened asphyxia.

Moreover, in reference to the point in dispute between Dr. Wardell and myself, viz., the rapid production and removal of œdema, as an effect of inflammation in the glottis, I would call his attention to an equally sudden change in the condition of the parts affected in erysipelas, particularly when treated by nitrate of silver, the action of which I consider almost identical with that of the alum. In the phenomena of a common black eye, we observe a similar rise and subsidence of the tumefaction. The bites of insects and other irritations afford numerous illustrations of this fact. Besides, in so narrow a chink as that of the glottis, a very small additional amount of swelling may easily produce all the difference between an impeded and an obstructed respiration, so that without any apparent increase of the general symptoms of inflammation, a sudden dyspnœa may arise, exhibiting phenomena peculiar to itself, as though a new disease were engrafted upon the pre-existing one. How many persons would be suffocated by common "colds in the head," if we had not the power of breathing through our mouths, when our nostrils are closed by the tumefaction of the mucous membrane. But not to mention fatal cases of *sudden death* that I have seen from œdema of the glottis, I beg to refer Dr. Wardell to Dr. Smith's third and fatal case of laryngitis, in which this morbid state occurred, when it did not appear to have been suspected; also to an instructive case of fatal laryngitis treated by Dr. Bell Fletcher, of Birmingham, and recorded in the *Provincial Journal* for May 3rd, in which, during the operation of tracheotomy, upon cutting through the mucous membrane of the trachea, dark bloody serum flowed from the wound and mouth in large quantity. Dr. Fletcher states that he had observed the same occurrence at a previous operation; and he was led to believe that the serous fluid probably issued from *the submucous cellular tissue of the larynx, which was likely to be in a very œdematous condition.*

Dr. Wardell refers me to Sir H. Marsh, to the "Cyclopædia of Practical Medicine," and to Dr. Laycock, on the "Nervous Diseases of Women," for instances of "pure uncomplicated spasma glottidis in the adult;" but having omitted to mention the pages in which such cases are comprised, I have not been able to find them, though I have searched the original works for the purpose. I did, however, find that Sir H. Marsh expressly *restricts* this disease to the "period of infancy." Dr. Joy, the writer of the article "Spasm of the Glottis," in the "Cyclopædia of Practical Medicine," says "fatal spasm of the glottis in adults takes place occasionally under the influence of irritating causes in the neighbourhood of the larynx, from food sticking in the œsophagus, &c.;" and he mentions an instance of its occurrence "in the *course of acute laryngitis*, when very little redness was discoverable after death in the lining membrane of the larynx, and scarcely any other morbid appearances than one or two minute ulcers." Lastly, Dr. Laycock, *Op. cit.*, p. 180, mentions a case in York Hospital, of a patient whom he found in a comatose state, from a sudden attack of hysteria, combined with epilepsy, which had induced asphyxia, and which he succeeded in relieving by introducing his finger into the throat; and his observation upon it is—"In this patient hysteria had passed into epileptic paroxysms, and it is *in such cases* that we have laryngismus stridulus." Are these, then, the authors on whom Dr. Wardell relies for accounts of pure uncomplicated cases of spasma glottidis in the adult?

Not content, however, with this accordance with my own views, I continued my search, and found the following under the head "Spasmodic Affections of the Larynx in the Adult," by Dr. Williams, "Library of Medicine," vol. 3, p. 64:—"Spasmodic affections of the larynx in the adult occasionally occur as the results of more distant spinal or nervous irritation under the garb of hysteria;" and he then describes globus as attended by it, and as being relieved by eructations. "More rarely," he adds, "the constriction is of a more enduring kind, and accompanied by fits of croupy breathing, and a convulsive ringing cough. Like the crowing inspiration of infants, this may arise from temporary irritation, or from more permanent diseases of the nervous centres." As Dr. Williams, however, cites no cases, we cannot conclude whether the instances he alludes to are the more violent ones of threatening asphyxia, or merely the painless but distressing gaspings and sobbings, and spasmodic cough, so commonly observed during the hysteric paroxysms.

In further proof that the more violent form is very rare, I may mention that during my search for authorities, I asked a physician of great experience, whose work on the "Practice of Physic" has been a text book for many years, whether he had met with such cases, when he replied in the negative. But as Dr. Wardell has no reverence it seems for great names, I forbear to mention the name of this gentleman, particularly as my allusion to Dr. Copland's not having admitted spasm of the glottis into his dictionary under that

name, (I had not then seen the article larynx,) has not only excited Dr. Wardell to have a fling *en passant* at the "great book-maker," as I suppose, for his omission, but also it has somehow or other made it appear to him, Dr. Wardell, that I "am not aware that this affection has long since been written upon under that appellation." It has been truly said that there are more false facts than false theories in medicine,—that is, facts become falsehoods by their misinterpretations and misapplications, and hence there is the greater reason that nothing admitting of doubt should, as in Dr. Wardell's cases, proceed *ex cathedrâ*; yet in no disease has this confusion arisen worse than in the affection before us. Now, had Dr. Wardell cited only the case of his Edinburgh patients, as an instance of spasm of the glottis in the adult, I should probably have never thought of controverting such a fact, or the opinion deduced from it; but when I found he based his notions upon cases that were evidently inflammatory, and that others imitated his example, I thought the matter was of sufficient importance to be put in its true light. To revert to the cases of Mr. Gorringe and Mr. Alford: in the latter the uvula is stated to have been "inflamed, and much elongated;" and Mr. Gorringe's patient "had been suffering from difficulty of breathing for more than twelve months, and the complaint is daily getting worse;" yet these are adduced as cases of pure uncomplicated spasm of the glottis in the adult. I confess Dr. Smith's case of the "lad," made me think I might have been too hasty in my denial of the existence of the disease in the adult; but having had an interview with the patient, I found him to be a mere boy, who had been subject to croupy attacks during sleep, (but *without his being awakened* except by his friends,) ever since he was eight years old; and that the last attack occurred on the 11th ult., in the afternoon, having been preceded by *dryness and pricking* in the throat in the morning, and was relieved by an emetic, so that he was as well as usual by midnight. Without, therefore, denying its possibility, I must repeat that Dr. Wardell has not proved the existence of the disease in the adult, such as we have it in children; for I think the Edinburgh case too meagre in its details to warrant our resting upon it, particularly as Dr. Wardell did not see the patient at the commencement of the attack.

I am also asked if I mean to assert that in spasm of the glottis, there is *complete closure* of the rima, and no room at all left for the passage of the air. Most undoubtedly I do, as I believe this to be the case in the disease as it occurs in infants and young children, and as it is described by Marsh, Clarke, Cheyne, and Ley, in these or similar words:—"The child is seized suddenly with a spasmodic inspiration, consisting of distinct attempts to fill the chest, between each of which a squeaking noise is heard; at length a strong inspiration takes place, a fit of crying occurs, and the patient falls asleep, if it has not died during the fit." This is true spasm of the glottis, and is clearly distinguished from the other laryngeal affections by Dr. Copland, *oc. cit.* But if Dr. Wardell wishes to know my opinions of the nature and cause of spasm of the glottis, I beg to refer him to my paper "On the Pathology of Hooping Cough," in the *Provincial Journal*, for October 8, 1847, where I have incidentally touched upon this complaint. Apologising for trespassing upon so much of your space,

I am, Sir,

Your obedient servant,

T. OGIER WARD.

Kensington, July 1, 1848.

CASE OF ABSCESS OF THE BRAIN.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Having but lately had an opportunity of seeing your valuable periodical, and the willingness you display in throwing open its columns for the information of all, induces me to intrude the following case under your notice:—

A considerable period ago I was called on by a friend to attend his daughter, aged 13, who had been unable to attend her school for a week before, with severe headache. When I saw her she complained of pain extending over the entire right side of the head; left, not at all affected; pulse rather quick; bowels regular; tongue clean. She had constant discharge of fœtid matter from the ear of that side. This had been the case for a period of two years before, at which time she had received a heavy fall on ice, which had left her senseless for some time. But from that period to the occurrence of the headache she had enjoyed uninterrupted good health, had grown much, and her strength was such that she carried her father, a large powerful man, all round the room on her back, the Sunday before. I noticed that she had slight strabismus of the right eye, and the pupil was a little more dilated than the other.

I had her head shaved, leeches applied to the temple and behind the ear, and ordered a bolus of Calomel., gr. iij.; Scamon., gr. x., at bed-time, and an aperient draught in the morning.

I attended her every day for five days, during which time there was no abatement whatever of the pain, but rather an increase of it and the strabismus; also of the enlargement of the pupil. About the third day the sight failed, and in a few hours was gone altogether. She maintained all through the most perfect consciousness, but a few hours before her death, began to call repeatedly for her father, and when he spoke she would say she did not know what she wanted him for. She died without any convulsive movements whatever.

On examining the head, ten hours after death, the dura mater appeared perfectly healthy, but on dividing the membranes, the entire right hemisphere dashed in a torrent through my fingers, in the form of a thick, smooth, and green pus, of a most intolerably fœtid odour, so overpowering that the father fainted before he could get out of the room. The left side and the cerebellum were perfectly healthy.

There had not been paralysis of any of the members that I could observe, but she had frequently remarked a numbness of the right arm for a long period, and

did not move it as much immediately before her death as she did the left.

Perhaps some one of your correspondents might take notice of this case, for I should be glad to know whether this extensive lesion could have been the result of such a few days illness, or could it have been constantly progressing since the period she received the fall.

I am Sir, your obedient servant
AN IRISH APOTHECARY,

August 25, 1848.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF PROFESSOR SANDS COX, F.R.S., SENIOR SURGEON TO THE HOSPITAL.

Reported by PETER HINCKES BIRD, Resident Medical Officer.

CASE IV.

COMPOUND COMMINUTED FRACTURE OF THE RADIUS AND ULNA.

Cornelius Mollick, aged 40, employed at the Chemical Works in the neighbourhood, admitted into the Queen's Hospital, under the care of Professor COX, at half-past twelve, p.m. He states that about a quarter of an hour since his left arm got entangled in an iron spindle; he immediately lost the use of his arm, which became much deformed, and he received a large lacerated wound. He lost but little blood at the time of the accident. Has always enjoyed good health, and been of temperate habits.

On admittance, it was found that he had received a compound fracture of the radius and ulna of the left arm; there was a large lacerated wound on the inner side of the arm, extending from the lower to the middle of the upper-third. On introducing the finger into the wound, the fractured bones could be felt. Both the radius and ulna were broken in two places, the lower fracture being about two inches from the wrist, and the upper in the middle third. The wrist-joint was not injured. There was also a small lacerated wound on the outer side of the lower-third of the arm, but it did not communicate with the other wound. Complains of great pain. Pulse feeble, 86. The fracture was reduced, and the injured arm placed on a splint, and water-dressing applied, and a draught, containing Liq. Opii Sed., m. xxx., administered.

October 2nd. Slept but little last night, the pain kept him awake; pulse quick and strong; tongue rather furred; bowels confined. Broth diet. Lemonade. Capt. Mist. Salin., oz. j., quartis horis. Extr. Col. Co., (Palmeri,) gr. x., statim. The arm to be kept damp with cold water up to the shoulder.

3rd. Much the same; the pain is easier; the wound looks healthy; some œdema of the hand; bowels open; tongue slightly furred.

4th. Slept well last night; complains of but little pain in the part; bowels open.

5th. Slept very well last night; bowels confined; tongue clean; pulse 84, rather feeble; appetite good; the wound looks rather sloughy, but gives him no pain. Cont. mistura et pilulæ. To have light pudding, &c. A bread poultice to be applied to the wound.

6th. Slept well last night; bowels open; tongue clean; pulse rather feeble; appetite good; the wound looks cleaner, and its margins are slightly inflamed.

7th. Sleeps well; pulse feeble, 67; the wound looks healthier, and discharges freely into the poultice. Meat diet.

8th. Doing well; feels comfortable; bowels open; pulse regular, 65; tongue clean; has had no rigors; the wound looks healthy, and discharges freely; there is no collection of matter; complains of an occasional jumping of the fore-arm over the seat of the fracture; the œdema of the hand is considerably less.

11th. Feels better; the wound looks well, and discharges a thick, healthy, pus; the jumping of the fore-arm is not so frequent; bowels open; tongue clean; pulse regular.

12th. Wound looks healthy; the bones are in good apposition; health improves. To have the edges of the wound brought into close apposition, and the wound to be dressed. R. Acid. Nitr. dil., dr. iss.; Decoct. Cinchon., Oss.; Tinct. Cinchon. Co., oz. ss.; Sum. oz. iss., ter die. Extra diet. Ale, one pint daily.

16th. Improving; the wound is rapidly healing; is in no pain; general health good.

25th. The wound has healed considerably since last report, but the granulations are now large and flabby. The wound to be dressed with sulphate of zinc lotion.

28th. Doing well; the bones are in good position. To have the wound dressed as usual, and the fore-arm put in splints. Ordered to get up.

November 3rd. Much improved in health; the wound looks healthy, and is nearly healed.

10th. The wound is quite healed over, and the bones are firmly united; can use the arm well. Discharged.

When this patient was admitted, the first question was, whether an attempt should be made to save the limb; and indeed nothing is so difficult, or requires nicer judgment, than to form a decision as to the propriety of amputating in some cases of compound fracture. The difficulty, however, does not only exist with regard to the state of the limb itself, but with the constitution of the patient; for there may be two patients, with precisely the same extent of injury attendant on the fracture, and the fracture itself may be in the same part of the limb, and yet there may be so great a difference in the strength of the constitutions of the two, that in the one case the limb will recover without any bad symptoms arising; while in the other, if the limb be left on, it may ultimately be necessary to remove it, and perhaps the patient may lose his life from the irritation produced to the system generally. In the above case the accident occurred in a man possessing a good constitution, and in one of temperate habits; had it happened to a drayman, or to a cabman, or indeed to any one of irregular and intemperate habits, the result would, most probably, have been different.

It becomes important therefore to consider these points, before deciding upon the question of amputation, and not to look merely to the state of the limb, but to weigh them well in mind; ascertaining, if possible, the previous habits of the patient, the strength of his constitution, and the state of his general health; attending also to the state of the limb itself,—considering the kind of force that acted upon the soft parts, whether they have been crushed or torn,--how far they are separated from the bone,—whether any great vessel has been wounded,—and, if the fracture be comminuted, whether the portions of bone are completely separated, or are still adherent to the periosteum. It is of the highest importance to ascertain the extent of injury done to the soft parts around the bone, for if they have been crushed, as by a heavy weight falling upon them, the consequences to be expected are,—great sloughing and the exposure of the fractured ends, and great constitutional disturbance, which may be sufficient to prevent the union of the fracture altogether, and very often to endanger the life of the patient.

In the above case the following points may be considered as influencing the decision in favour of amputation:—The fracture was produced by a direct force of a very violent nature, the soft parts being crushed and lacerated; the fracture was comminuted, and the wound freely communicated with the fractured portions; but on the other hand, no large artery was torn through, nor did the fracture extend into any joint, nor was the bone much comminuted, and above all, the patient possessed an excellent constitution. An attempt was therefore made to save the limb, the fracture being first reduced, and then the sides of the wound brought together, and dressed with water-dressing, followed by the administration of opium.

PROVINCIAL
Medical & Surgical Journal.

WEDNESDAY, SEPTEMBER 6, 1848.

From various unavoidable circumstances, we have hitherto been prevented from alluding to the proceedings connected with the dispute between the Guardians of the Upton Union and their Medical Officers. The Upton Union consists of five Districts, to each of which a medical officer is attached, but with salaries so insufficient, that after repeated remonstrances and fruitless applications for an increase, the gentlemen holding these appointments at length unanimously resigned. The Board thereupon advertised for new officers, but for some time unsuccessfully. At length, however, with some exertion and much personal canvassing, far and near, to induce other medical men to come forward, the Guardians succeeded in patching up a temporary medical staff. Two of the districts were confided to one practitioner, who had been previously dismissed from their service; a third district to another practitioner whose qualifications we are assured will not bear investigation; a fourth district is still vacant, but entrusted temporarily to the practitioner already burdened with a double charge; and the remaining one, we regret to say, a highly respectable gentleman has been induced to undertake, though even in this case also the Board would seem to have acted illegally in making the appointment, as the qualification, we are given to understand, is a single one—that of member of the Royal College of Surgeons only, instead of the double qualification required by the regulations of the Commissioners.

We can conceive nothing more pitiable than the situation into which the Guardians of this Board,—before distinguished by certain dubious transactions with former medical officers,—have thus reduced themselves. After weeks of a contest, which has betrayed the extreme of shabby misconduct on their part, the interval employed in personal solicitation by individual members of the Board, their abortive efforts have resulted in appointments which cannot stand, and an investigation of the circumstances by an Assistant-Commissioner, sent down for the purpose, which, if Mr. Buller is in earnest in his professions, can have no other end but a defeat, as disgraceful as has been the conduct of the Board throughout the transaction.

Our object, however, on the present occasion, is not so much to expose the misconduct of the Union authorities, as to point out for imitation the admirable manner in which the late Medical Officers have acted. Having, in the first instance, shewn the utter insufficiency of the salaries, and applied for an increase, on the Board refusing to listen to their application, they at once resigned. On the Guardians advertising their terms, and for gentlemen to undertake the medical care of the districts, the late Medical Officers pointed out the insufficiency of the terms offered, at the same time shewing what ought to be the amount of the salaries, and stating their willingness to undertake the duties again, provided such sufficient salaries were granted, thus not leaving the Guardians the excuse for their improper choice of medical officers, pluralities, &c., that they were driven to these irregularities from the want of other and more fitting candidates. In this proceeding, and indeed throughout, the medical officers have exercised a sound discretion, and we cannot but

feel a well-grounded expectation that success will attend their efforts.

Before bringing these observations to a conclusion, we are desirous of offering a remark on the general question. It may be thought by some that, on this and some other occasions, we have taken too one-sided a view of the subject, and that while we have freely pointed out the misdemeanours and short-comings of the Poor-Law authorities, we have been blind to those instances in which the system has been carried out in a more satisfactory and liberal manner. We are quite aware that in many places to which we could refer, the conduct of the Boards of Guardians is regulated by more liberal and more enlighted principles,—that the Medical Officers are treated as gentlemen, their representations and advice listened to with respect and attention, and their salaries, on the whole, and all circumstances considered, not inadequate. But it is the ill-working of the system under the management of the ignorant and self-interested, by far, as respects medical affairs, the majority of those from whom Poor-Law Guardians are selected, that we feel ourselves chiefly called upon from time to time to expose; and that because we are convinced that the mode of appointment of the Medical Officers, and the control exercised over them by the Guardians, cannot but be, in the far greater number of instances, injurious both to the character and independence of the Medical Officers and to the best interests of the poor.

Let us only consider for a moment what would be the inevitable result, were the appointment and control over the surgeons of the army to be vested in the officers of the several regiments to which they are attached, and that the amount of salary was at the same time to be paid out of funds contributed by the officers themselves. We suspect that the Army Medical Department would be in a very different state of efficiency to that in which it now is, and that the *status* of the regimental surgeons would not, in some regiments, be greatly superior to that of the drum-major, or any other non-commissioned officer. The manner in which naval surgeons have of late been treated by officers in command of ships, and the station attempted to be assigned to them by a junior Lord of the Admiralty, will, indeed, afford a sufficient answer, and clearly shew the necessity for having the regulation of the medical services of the public, whether military or civil, at all times placed in the hands of those only, who are able aright to estimate the duties to be performed, and the character and acquirements of those who are to perform them.

Reviews.

On the Cure of Cataract, with a Practical Summary of the best Modes of Operating, (Continental and British.) By Hugh Neill, Surgeon to the Liverpool Eye and Ear Infirmary. 1848. pp. 224.

The accomplished surgeon, who is the author of the work before us, commences with some general remarks on cataract, in the course of which he alludes to a case published in the printed report of the Liverpool Eye and Ear Infirmary, which is so remarkable, reflects so much credit on his own benevolent disposition, and displays in so striking a manner the deep obligation we ought to feel to an Omnipotent Power in aiding our efforts in the healing art, that we cannot resist the desire to present it to our readers in the simple and beautiful language in which it stands recorded.

"Of the cases now in the hospital, one deserves a little notice; it is that of a nice, modest, intelligent young woman; her age is 23, and she is married. From her gentle and quiet submission under operation, and her conduct during treatment, she has created a lively interest for her welfare among the visitors, and indeed throughout the whole establishment.

"Her story is this:—Soon after her marriage her sight failed, and at last she became blind a few months before the time when she would become a mother. I can easily imagine her deep distress: her hopes of happiness broken down, her future prospects dark and lamentable; what under other circumstances would have been her *joy* was now her fear, her wretchedness. To be a blind mother; not to see her baby or its smile, nor to be able to watch its sleep, and its happy dreams, nor to scan it in pain or in sickness; nor even to see her husband, an industrious and thriving mechanic; not to be able to be his help-mate; dependent, young, yet blind; strong and otherwise healthy, yet useless. I saw her when she came to our hospital, bowed down, almost to broken-heartedness. I shall not soon forget her expression when I pronounced the word *hope*.

"I debated in my mind whether to let her hour of trial pass; or, should I venture to operate; might I act as the instrument of the Great Power and open this poor woman's eyes before the time of her trouble. I did operate on both eyes, and she bore the process well. Not a particle of inflammation succeeded. The case is progressing most favourably, her health is good, her spirits are high, her hopes are strong, and she feels that she has been blessed; she now can see, and she waits with patience, and looks forward with pleasure to the time when, (to use her own words,) she shall be a happy, happy mother."—pp. 7, 8.

After describing the various forms which cataract assumes, the author proceeds to the treatment; and here

we must interrupt our remarks by engaging attention to the vast advantage resulting to the patient, and to the reputation of the surgeon, by minute regard being paid to every circumstance calculated to contribute to a successful result. The happy termination of many of the most dexterous operations has been prevented by that carelessnes and indifference which great surgeons are too apt to indulge, who, having acquired popularity and self-conceit, consider it beneath their notice to extend their attention to the after-treatment. Such men as these should read the following truthful remarks of the author :—

"I have the vanity to consider myself a successful operator, and if it be egotism to speak from the results of 600 operations, publicly verified, then am I also an egotist in priding myself in the reasons for the success attendant on my operations. The secret is, I have sedulously cared for that result, by studying the most likely means to *secure every possible advantage to the patient*; and I am confident that the explanation of the triumphs of favored and distinguished hospital operators, in every field of surgery, when analysed, will be found also this: that however adroitly the operation is performed, through the exercise of natural gift, perfected by frequent practice, which begets 'a property of easiness,' still *eminent success* is owing to the coalition of pains-taking surgery, with due management of the system *before* and *after* the operation, as much as to enviable address in handling the knife or needle."—p. 21.

We may generally conclude that the only mode of treatment which holds out any prospect of a cure for cataract is some operative proceeding, and even this requires caution and experience to enable the surgeon to decide, what may, and what may not, be proper cases for chirurgical interference. Among the different objections to any operation, the author by no means includes infancy, as children during the first weeks after birth may become the objects of it; and it should, if possible, not be delayed in them beyond the third year, on account of the habit they may acquire of rolling about their eyes, and their reliance on the sense of touch, both of which may prove a great disadvantage after the operation. With respect to the disputed question,—whether the operation ought to be performed on one eye, while the sight is perfect in the other, we think the decision ought to depend upon circumstances. For instance, in cases of traumatic cataract, in which the habit of viewing objects with one eye, must be suddenly acquired, and much confusion of sight must consequently exist, we think, if the patient should wish it, the operation may be undertaken without hesitation. A blacksmith consulted us respecting confused vision, which arose from cataract in one eye, the result of accident. The confusion in his sight was so great that he could not with any confidence apply the nails to the horses' shoes in the operation of shoeing. We operated with success on the cataract, and the patient was afterwards able to shoe horses as well as before the accident. We think, too, that it is the best practice to operate on both eyes at the same time, when both are affected, unless there may be some sufficient reason for a contrary proceeding; and we give this opinion as the result of our own experience.

For the purpose of dilating the pupil various vegetable preparations have been employed. Amongst them the author informs us, that Battley's Liquor Opii Sedativus, will be found capable of effecting our purpose. The best preparation, however, he says, is the muriate of atropine, a chemical preparation of the Atropa Belladonna in common use.

In describing the preliminary steps necessary for an operation for cataract, the author seems to be, properly, much opposed to the use of instruments for securing the eye in a steady position and elevating the upper lid. In all our operations for this disease, except extraction, we, ourselves, have almost always dispensed with every kind of aid to ensure the elevation of the upper eye-lid our custom being that of separating the lids by means of the finger and thumb of one hand, while the other is occupied in the use of the needle.

In describing the operation of extraction, which in some cases is preferable to any other, the author attaches great importance to the size of the incision through the cornea, which should always be made of sufficient extent. Most young operators fail by making the corneal section too small.

We cannot too much admire the simplicity, which Mr Neill observes, with respect to the instruments employed by him in this capital operation,—a certain proof of a great mind and a masterly knowledge of his profession. Hence, instead of the old-fashioned cystotomes, which were formerly paraded as indispensible auxilliaries, he only applies the cataract-needle for the purpose of lacerating the capsule and facilitating the escape of the lens.

The operation by *depression* is of great antiquity, and when we reflect on the large size and clumsiness of the instruments formerly employed, we cannot help feeling astonished that the human eye should ever have escaped irreparable injury from the rude operations, to which it was subjected even within our own recollection. The author, for this operation, prefers the curved to the straight needle, as he considers that it is less likely to injure the iris. For his description of the operation of depression, we must refer our readers to the work itself; but we cannot resist our inclination to put them in possession of his cautious proceeding after the operation, to ascertain from time to time the state of the conjunctiva; it being with most others a general rule to avoid any attempt to view it before the sixth day.

"Whereas, I caution the surgeon never, in the first six days after the operation, to let twelve hours pass without inspecting the *conjunctiva*, by gently drawing down the lower lid. Very often have I saved my patient's eye by such a peep, when inflammation has been going on, and no announcement of it made by pain; but having seen it, of course I checked its progresss." p. 56.

The operation of *reclinaion* consists in displacing the

lens, so that its upper margin is brought into the front of the eye, and its lower edge is placed backwards. In this operation care must be taken to avoid the iris, and to prevent the needle from penetrating the lens; and should one of the ciliary vessels be wounded, so as to render the proceeding obscure, the author advises the instrument to be withdrawn, and introduced again on another day. The object of reclination is to expose the lens to the absorption or solution effected by the aqueous humour. When the lens continues unchanged three or four weeks, or when it advances through the iris, and compresses that part, extraction should be performed. Should the operator carry his depression of the lens too far, there may be danger of retinitis and amaurosis ensuing, which must be obviated promptly by antiphlogistic treatment. In the operation we are speaking of, the needle is usually introduced about a line and a half or two lines from the edge of the cornea, either above or below the situation of the long ciliary artery. Some surgeons adopt another proceeding called *keratonyxis*, which consists in the insertion of the needle through the front of the cornea. This operation, we believe, is seldom, if ever, adopted in this country, on account of the danger of exciting inflammation and its consequences in the cornea. The process of breaking up the cataract is alluded to by the author, who candidly states its advantages and disadvantages. One of its greatest objections we have found to consist in the pressure of its fragments, or of the greater bulk of the lens itself upon the iris, when they are lodged in the anterior chamber.

For *children*, and for the *soft milky* cataract, we have found *discissio*, or the operation by incision, by far the most eligible, and it is sometimes astonishing to witness the rapidity with which the lens and capsule are removed after they have been exposed to the action of the aqueous humour. The needle used for this operation is a straight one. The one we employ is lancet-shaped, and very small. It may be introduced, either through the sclerotic coat, or the cornea. The latter is the most advantageous situation for the surgeon, and should, in the opinion of the author, always be preferred, unless the state of the cornea should contra-indicate its employment. With a needle of proper size and shape, this operation is almost painless.

It was formerly the practice invariably to bleed the patient after every operation for cataract. Mr. Neill, with great justice, condemns this wholesale venesection, and adapts his practice to the state and constitution of the patient, and at the same time with becoming liberality, makes every possible allowance for different habits of life, and the variations in atmospherical influence, which may formerly have suggested universal depletion. When speaking of cold applications to the eye after the operation, which are found by all modern practitioners highly beneficial, and generally very comfortable to the patient, we are pleased to find that the author intends to present to the profession another acceptable contribution to ophthalmic surgery, on the subject of rheumatic ophthalmia. The remaining directions for the after-treatment are excellent.

We shall resume this notice on another occasion, at present we are unable to continue our remarks at greater length.

The British and Foreign Medical Review, or Quarterly Journal of Practical Medicine and Surgery. Edited by JOHN FORBES, M.D., F.R.S., F.G.S. Vol. XXV. being a General Index to the preceding Twenty-four Volumes. London. 1848. pp. 303

Those only can appreciate the value and importance of a good Index who have been called upon to turn over pages and volumes, and to look through brief tables of contents, of works deficient in such an aid. The loss of time, and too often fruitlessly, which may be spent in such "a pursuit of knowledge under difficulties," must have been personally felt before we are in a condition sufficiently to estimate the advantages of the volume before us. Of course we should not be able to ascertain how completely the compiler of this index has executed his task, without much and laborious reference, but we can say, from the examination of several portions of it, there is every reason to believe that it is throughout well and faithfully performed.

The late *British and Foreign Medical Review*, with the exception of some small blemishes, to which we need not here further allude to, may be considered as a faithful digest of nearly all that is most vaulable, which appeared in the several branches of medicine, during the twelve years of its existence, as a periodical. By the publication of this Index, its contents are readily and at a glance laid open for reference to all who may have occasion to consult the medical literature of the period. We need say no more in commendation of the Index; it is indispensable to those who possess, or have access to, the volumes of the *Review*. But we observe from a notice on the cover, that a few complete sets of the *Review* may yet be had; with the aid of the index these are now become of great value, and we would earnestly recommend to those who are engaged in the pursuits of medical literature, not to let the opportunity pass of obtaining so complete and valuable a record of an important portion of it.

We take this occasion to announce that there is a prospect of another medical periodical being rendered similarly useful. A notice appears in the *London Medical Gazette*, that a General Index to the first forty volumes of that work is in contemplation, and will be commenced as soon as the names of five hundred subscribers shall be obtained. We shall be glad to learn that the list is speedily filled up.

Proceedings of Societies.

SOUTH-EASTERN BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.*

The Secretary read part of a letter he had received from Mr. Hunt, of Herne Bay, regretting his unavoidable absence from the meeting, and stating,—that had he been able to be present, he would have given a full report of the experience of the members of the Association, who had informed him of the results of their practice in the administration of arsenic, a portion of which information had appeared in the Journal of the Association; and that out of the records of a multitude of cases, in no one instance did it appear that the medicinal exhibition of arsenic, not always cautiously administered, has proved either fatal, or seriously detrimental to the health, which is more than can be said of any other very active medicine.

ON THE INTRODUCTION OF THE CATHETER.

Mr. Giraud, of Faversham, favoured the meeting with the following observations on the introduction of the catheter:—

Having frequently experienced difficulty during a period of more than twenty years in introducing the catheter for retention of urine, caused by the enlargement and altered structure of the prostate gland, I have been lately struck with the uniform facility, in two cases, with which the elastic catheter passed into the bladder without the stilette, by simply passing it along the urethra, and allowing it to take its own direction. No doubt all have met with instances in which the various methods proposed for meeting this difficulty have more or less failed; such as using a very large silver catheter, advised for this purpose by Sir Astley Cooper, and the plan recommended by the same surgeon, of passing a full-sized catheter down to the part, then depressing the point, and canting it over the third lobe. Also Sir Bemjamin Brodie's recommendation of using an elastic gum catheter, and partially withdrawing the stilette when it reaches the third lobe, for the purpose of raising the end of the instrument.

About two years ago, having been called to a case of retention of urine from prostatic disease, in which the forementioned methods had occasionally failed, more or less, and pain and difficulty been experienced, I used a full-sized elastic gum catheter, without the wire, and was surprized to find how easily it found its way into the bladder, and it has continued to do so up to the present time, the patient frequently passing it himself without my assistance. I have adopted this mode of relieving the bladder in a second case, which had often given me much trouble, and with the same uniform success. I think it is my duty to state this simple fact in relation to the use of the catheter in prostatic disease, but which perhaps may be already familiar to many members of this Branch; but if one only of us should have been ignorant of it, some degree of embarrassment on the part of the surgeon, and much pain to the patient may be spared, even if this method be found to be applicable only to one peculiar condition of the urethra under prostatic disease.

* Continued from page 412.

HYDRIODATE OF IRON AND QUININE.

Mr. Samuel Battley, M.R.C.S., communicated some observations on the therapeutical effects of hydriodate of iron and quinine.

It has long been observed that some of the preparations of iron exercise a much more decided and more rapid influence on the system than others, and more especially the proto-salts. The sesqui-oxide, or carbonate of the Pharmacopœia of 1824, from its insolubility, is absorbed with great difficulty, and although a large quantity may be taken into the stomach, only a small portion enters the vessels and exerts its tonic influence on the system. The proto-salts being more soluble, are more speedily absorbed, and more rapidly display their action. In addition, however, to this character, they possess another advantage, namely, that on mixing with the venous blood, they become decomposed and unite at once with the carbonic acid, which is a never failing constituent, and one of the forms assumed by the debris of wasted tissue.

When iron is saturated with oxygen, and in the state of peroxide, it loses its power of combining with carbonic acid, which it possesses only while in the state of protoxide. The carbonate of protoxide thus formed is conveyed to the lungs, while the carbonic acid is evolved in its passage, and removed from the system. A corresponding volume of oxygen is then absorbed by the iron, and conveyed by the circulating fluid to every part of the system, to sustain its temperature and other functions essential to life. Iron, when presented in this condition, exerts a two-fold action, namely, that of purifying the blood, by removing its carbonic acid, and by absorbing and yielding oxygen.

As a compound lately offered to the profession, of great value, the syrup of the hydriodate of iron and quinine may be mentioned, in which are combined one of the most powerful and efficient vegetable tonics, namely, quinine, iron in its most active state, and iodine in the form of hydriodic acid. The iron being in the state of proto-salt, more speedily becomes absorbed, and more rapidly displays its action on the system than when in that of per-salt, especially peroxide, but in this preparation, preserves its maximum activity.

The object of combining these two bases with a third element, has been to introduce a substance which, by its action on the secreting organs, and more especially on the function of the liver, will diminish the tendency to constipation, febrile irritation, and other inconveniences which frequently attend the use of, and to some extent diminish the benefit to be derived from, these powerful tonics.

The following is a convenient form of exhibiting the compound:—

R. Syr. Ferri et Quinæ Hydriod., scr. j.; Aquæ Cinnamomi, oz. j.; Syr. Cort. Aurantii, dr. j.; Tinct. Cardam. Comp., dr. ss. M. Fiat haustus bis quotidie sumendus.

The author received the thanks of the meeting for

ably communication; and for the exhibition of some of Mr. Battley's specimens of materia medica, of the finest quality.

A conversation having arisen on therapeutical principles, Mr. Trustram made some observations on those rational and general principles which ought, in his opinion, to guide the practitioner in the treatment of disease, grounded on general indications, modified, of course, by the peculiarities of each individual case, rather than on a *methodus medendi*, based on the efficacy of specific remedies, with their more general or even almost universal application.

ON SPECIFICS: BI-TARTRATE OF POTASS IN UTERINE HÆMORRHAGE.

Dr. Silvester, of Clapham, read portions of a paper, and made some remarks on specifics in general, and on the employment of the bitartrate of potash as a remedy for chronic uterine hæmorrhage.

Specifics are defined by the best authors to be those remedies, simple or compound, whose virtue is peculiar in some particular diseases. The most remarkable examples of this class of medicines are bark, mercury, iodine, sulphur, colchicum, and a salt, now proposed to be added to the list, of equal efficacy and value to either of the above-mentioned medicines, namely, the bitartrate of potash. A prejudice exists universally against the term specific; the idea is associated in the mind with that of quackery; the quack has adopted the term from the nomenclature of our art, but he is far from possessing what it legitimately signifies. The appropriate term of the empiric's "villanous compound" is "nostrum;" concealment and selfishness are the object and motive of its preparation and exhibition. Extraordinary, almost miraculous, powers were ascribed in ancient times to certain drastic or heterogeneous compositions, as the Pulvis Basilicus, the Hiera Picra, the Confectio Andromachi, and especially the Mithridate; but the treatment of disease, to any extent, by the exact application of remedial agents, each to its appropriate symptom, or combination of symptoms, should be regarded as of modern origin, and as an important improvement on the complicated, confused, and contradictory mode of prescribing, once thought so necessary, and even now not wholly relinquished. It would appear that, in no case, do any two medicines produce precisely similar or identical pathological or physiological effects in the human body. Coma and anæsthesia are equally induced by belladonna and by opium; but there is a perceptible difference in the character of the phenomena: and that the nervous system is not in the same condition, in both cases, is proved by the state of the pupil—widely dilated in the former, contracted to the size of a pin's point in the latter instance. If a large dose of opium be given immediately previous to the expected fit of an intermittent, deep sleep ensues, followed by excessive perspiration, and it often happens that the disease is cured; a large dose of the sulphate of quinine taken after the fit, is equally efficacious, although unaccompanied by either sleep or perspiration. The ultimate effect is the same, but the means by which it is accomplished on the internal organization probably differ. No satisfactory explanation indeed has ever yet been afforded of the changes which take place in the human body under the influence of medicinal agents. Modern chemistry has made the attempt, and much may be hoped, and perhaps expected, from its laborious investigations; but we must for the present be guided solely in the choice and employment of remedies, by extensive experience and accurate observation. Will the time ever arrive when the appropriate means of cure shall be able to be applied with so nice an adaptation to the numerous forms of disease as to exclude all uncertainty and hesitation? This is the true aim of our labours and researches; for scientific practical medicine consists in a discriminating knowledge of disease, or accurate diagnosis, and an exact application of therapeutical means. A practice based upon general rules, ill-founded perhaps, and certainly liable to many exceptions, will, it is to be hoped, give place ultimately to a method of cure arising out of a more precise observation of the phenomena of disease, and the peculiar or specific operation of remedial agents. The term specific is intended here to be used, not in its restricted sense, but in its obvious and grammatical signification; all scientific, must in one sense be viewed as specific, treatment.

Something like an approach to this rigorous adaptation of the articles or the Materia Medica, to the successive changing phases of disease, has been accomplished in regard to mercury, iodine, and sarsaparilla; with less certainty and exactness than could be desired, but with results sufficiently regular and constant to establish the reasonableness of an expectation, regarded by some as of too sanguine a character. It is well known that these three valuable medicinal agents cannot be prescribed successfully, if indiscriminately; that each has in the same case its limit of beneficial operation, and that they cannot be made with impunity to change places,—that is to say, one has no power of curing symptoms which belong to the other.

The unsettled rules of treatment, the varying fashion of medicine, and the excessive laudation, for selfish purposes, of inert or inefficacious preparations, have led to rash practice, servile prescription, or scepticism and indifference; and these evils it is feared will continue to exist until therapeutics, the most difficult part of our art, receive more attention from those (and they are few,) who are capable of the investigation. Anatomy, physiology, pathology, and chemistry, have been cultivated with industry and success. The method of cure, *par excellence*, remains comparatively a barren unfruitful region, overrun by empirics, or empirical practitioners. We have indeed thrown off the burthen of ancient complicated formulæ, with their endless list of heterogeneous ingredients; we no longer reverence the hidden powers of mithridate and other complicated medicines; but we have been unable to resist the temporary encroachment of a medical heresy and practice, (if practice it may be called,) which (the very opposite of excess in number and quantity,) attributes to the thousandth part of a single drug, more virtue than formerly had been supposed to exist in the thousand drugs themselves. This heresy is confessedly unable to bear the test of ordinary experience and

observation, and therefore may be left to its assured fate, but it is humiliating to reflect that it should have ever prevailed at all, and more particularly that it should have made converts from our own order.

It might not be amiss to observe, to prevent myself from being misunderstood, that in advocating the use of special remedies, in order to introduce, as I hope, more certainty into the practice of medicine, I by no means wish to undervalue the good effects of diet, rest, aperients, counter-irritants, the moderate loss of blood, and all the other usual means of relief or cure, which the recorded experience of ages has sanctioned, and the immediate salutary effects of which are at once apparent to those who are occupied in the daily duties of medical life. I hold that it is the duty of every member of our useful and influential profession, to exert his talents for the common good in the way which seems most suitable to his position or opportunities, and circumstances of a favourable kind have happened to lead me to study the power of single drugs, and uncomplicated preparations, over the body in disease. But the experience of one man is of little value compared with the collected experience of the members of a society like that which I have the honour to address. The country practitioner sees disease in its more simple and uncomplicated forms, and he has it peculiarly in his power to enrich the art of therapeutics. It is true that there are some obstacles in the way. Engaged in an active and laborious occupation, the medical man finds little time for recording his experience; or of retired habits, he is little inclined to appear before the medical public, with his really valuable contribution, aware of the opposition which every attempt at even useful innovation is apt to meet with. It is thus that many excellent suggestions, and most important results of experience, are lost or misapplied. He should remember, however, that we owe the proper method of proceeding in hæmorrhage during labour to Mr. Rigby; the discovery of arsenic for ague to Dr. Fowler; and opium in delirium tremens to Dr. Sutton, all provincial practitioners. I am indebted to our amiable and talented president, Mr. Hargraves, for a very sure method of treating varicose veins of the leg. It was said by the immortal Sydenham, that he had always thought it a greater happiness to discover a certain method of curing even the slightest disease, than to accumulate the largest fortune. Every right-minded member of the medical profession cannot but concur in sentiment and opinion with the English Hippocrates; it is a solemn duty incumbent on us all to contribute to the stores of medical knowledge every result of experience, calculated, in ever so light a degree, to lessen human suffering, or protract man's brief career on earth.

Last year, at the meeting at Reigate, I had the honour of reading a paper on the virtues of Iberis amara in cardiac hypertrophy attended with dropsy; further experience, unnecessary to relate, has confirmed my confidence in the salutary power which this plant of English growth possesses over the central organ of the circulation, suffering under morbid enlargement.

I now beg to call the attention of the Society to a remedy as well known, in some respects, to the public, as to the profession,—I mean the bitartrate of potash; everybody is acquainted with its cooling, diuretic, and generally aperient properties, but few are aware of its singular power in controlling uterine hæmorrhage. It is not without effect in bleeding from other organs, but I will reserve my observations on this branch of the subject till another opportunity, and restrict myself for the present to a few remarks on its efficacy in restraining chronic sanguineous discharge from the womb.

Uterine hæmorrhage may arise from various causes,—separation of the placenta or ovum, diseases of the heart and liver, polypus, malignant ulceration, fungoid growths, &c.; the bitartrate in such cases is equal to any other remedy in checking the discharge, at the same time that it allays feverishness and tends to keep the bowels regular. But it claims no superiority in these respects over many other medicines; it is in menorrhagia, or excessive menstrual discharge, prolonged continuously beyond its usual duration, or appearing at irregular intervals, that it displays its unequalled efficacy. Sometimes after abortion the patient continues to suffer from an occasional discharge which gradually ceases after inflicting much injury on the general health, and is with difficulty cured by tonics and astringents; it will in such cases be found to effect an almost instantaneous beneficial change. There are also instances met with in practice of a sanious or pale secretion from the uterus, sometimes treated as leucorrhœa by local astringents; they are accompanied by venous bruit, and are examples of imperfect menstruation. These yield rapidly to the bitartrate of potash, and, singular to say, the patient often recovers perfectly, without the administration of iron or other tonics. The foregoing description of the forms of disorder in which the salt alluded to produces a specific effect, will be sufficient for the information of the medical practitioner, who, after a little experience cannot fail to detect the proper cases for its employment. It would be tedious and irksome to relate individual illustrations in confirmation of the opinions advanced; they are easy of recognition, and the specific property of the drug is so conspicuously evident, that at the next meeting of our Society it is probable every member will be able to bear his testimony to the truth and accuracy of what has been now stated.

Without pretending to explain the nature of the salutary impression made by this agent on the solids or fluids of the body, I may be allowed to observe that when, as in chronic discharges, the blood is dark-coloured, it often becomes of a brighter hue, soon after the commencement of the treatment.

As I am exceeding the time* allowed for my paper, I will only relate another experiment and a corresponding observation. I had frequently noticed that whilst the patient was taking the bitartrate of potash, the urine remained perfectly clear when cool, although it had previous to the administration of the remedy, deposited, on cooling, urate of ammonia in abundance; but a solution of bitartrate of potash added to urate of

* Fifteen minutes is the time allowed by the Society for the reading of each paper at the Annual Meeting.

ammonia dissolved in warn water, did not prevent the precipitation of the latter salt, at a lower temperature. The urine becomes alkaline under the use of the bitartrate of potash; 95 parts of cold, and 15 parts of boiling water, are necessary for its solution. The solution it must be remembered is decomposed by long exposure to air, and will be found tc contain only carbonate of potash.

The gentlemen present then adjourned to dinner, at the conclusion of which, the thanks of the meeting were voted by acclamation to the president, for the friendly courtesy, and the ability with which he had fulfilled the presidency of the meeting.

SOUTH-WESTERN BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

The Annual Meeting of the South-Western Branch of the Provincial Medical and Surgical Association was held at Plymouth, on Tuesday, July 18th, John Butter, M.D., F.R.S., in the chair. Among those present at the meeting, were Dr. Kingdon, Mr. Barnes, Dr. Pennell, Mr. Pridham, and Mr. De la Garde, of Exeter; Professor Wood, of Philadelphia; Dr. Kane, of Exmouth; Dr. Soltau, Mr. Kerswill; Mr. Kerswill, jun., of St. Germans; Mr. Swaine, Mr. Fuge, Dr. E. Moore, Mr. Square, Mr. Freeman, and Mr. Stevens, of Plymouth; Mr. Ashford, of London; Mr. Langworthy, of Plympton Asylum; Mr. Puddicombe, of Dartmouth; Dr. Cookworthy, Dr. Barlow, Dr. Lea, &c.

The SECRETARY, Dr. Kingdon, of Exeter, read the minutes of the last year's meeting, which was held at Truro, and also part of a letter from Dr. C. Barham, the late President, regretting his unavoidable absence.

The PRESIDENT, Dr. Butter, then addressed the meeting, and thanked the members present for the compliment paid him voluntarily on their parts, and in a manner quite unsought for and unexpected by him, regretting that their choice had not fallen into better hands. He then congratulated all present on their professional zeal in coming so far from the East and the West to support the Association, and especially those from the east on their safe arrival over the South Devon Railway, which opened to Laira on the 6th of May last. He would not expatiate on those mighty powers—steam, atmospheric pressure, and electricity, to which they were indebted for the sight of their professional brethren living at a distance, although much might be said on electricity interesting to medical men. The Association of which this is a Branch, had existed for sixteen years, and had annually added to its numbers, which now exceeded 1800. Its objects are stated in the circulars:—For one guinea every member receives the volumes of *Transactions*, and a *Journal* every fortnight, giving a full account of the medical events passing in the world. This Journal has of late much improved in the variety and importance of its matter. There is also a Benevolent Fund for the relief of distressed medical men, their widows, and families. Once in every year these Branch meetings are held in large provincial towns, preparatory to the annual meeting, which this year will take place at Bath, in August.

The collection of useful information is one of the principal objects, but Dr. Butter would not detain the meeting with any observations, or retrospective view of the many discoveries recently made in medicine, as well as in science. He would pass lightly over the discoveries of Matteuci on electro-physiology, and the physical phenomena of living beings; and even those of Liebig, on the chemistry of animal fluids. His time would not allow him to dwell on the cell theory, or the formation of all bodies, animal or vegetable, healthy or diseased, from small cells or cytoblasts; nor on the transit of blood from arteries into veins; nor on the vibratile action of myriads of hairs in the brain and windpipe of animals, lately discovered by the microscope. As gentlemen present, were, doubtless, better informed than himself on these subjects, he would pass them over, with other topics of general interest, in order to speak more particularly of local things and persons connected with Plymouth. He must, however, first briefly allude to ætherization, discovered by Dr. Jackson, of America, from which so much practical information had been already transported into England by the eminent men of that country. Two years had scarcely elapsed since æther was proposed as an anæsthetic agent, to be inhaled into the lungs, in the form of vapour, as a means of depriving living beings of sensibility during painful operations. Scarcely had this discovery flown over the world with a rapidity almost of the electric telegraph, when Dr. Simpson, of Edinburgh, brought out a better substitute in chloroform. Last year, Dr. Butter was concerned in two very important operations on patients, who consented conditionally to their performance, provided that they could be ætherized, and deprived of sensibility for a time. In both instances, æther thus inhaled, intoxicated the patients to such an alarming degree, that the operations were delayed, and performed ultimately without its aid. Subsequently, he had tried chloroform in several instances with the readiest effects. He merely gave the result of his own experience without further comment, and thought that it never ought to be exhibited except by a medical practitioner.

Strangers having arrived at Plymouth naturally expect to be informed of the different medical institutions, places, and persons, dead or living, connected with our towns, of which he could only give a brief account. Plymouth, Stonehouse, and Devonport, are three towns, almost united into one, containing very nearly 100,000 inhabitants; Plymouth, 40,000. Compared with other towns they are generally healthy.

The *Workhouse or Hospital of Poor's portion* generally contained a great number of sick poor. Formerly one surgeon attended both to the in and out-door poor at a fixed salary; then two surgeons were appointed; but lately the Guardians have employed four surgeons, one for the house, and three for the out-door poor, at a salary of £40 a year each. They are elected by

a majority of votes. Great mortality prevailed here amongst the medical officers previousiy to this arrangement, as several had died through their arduous trials. It is lamentable to think that any well educated man can be found to attend 1800 patients, including sixty midwifery cases, accidents, operations, medicines, and attendance by night and by day, for a salary of £40, which is barely 5½d. per head.

According to Mr. Wyatt's statistical report, for 1847,

The average number of deaths annually is	850
Lowest mortality, in 1839.....	670
Highest ditto, 1842	1141
Year ending 30th June, 1848, still higher, being ..	1148

The increased mortality in 1842, was chiefly owing to the scarlatina, of which 400 persons died, and many children became deaf and dumb; and in 1848, to the measles, hooping-cough, bronchial, and pulmonary diseases. The mortality this year has been one in thirty-four. Notwithstanding this recent increase, Plymouth is healthier in the mean than Devonport, Exeter, Birmingham, Manchester, or Liverpool, being about the same as London. The cholera was very prevalent here in 1832, and more fatal than at any other place, excepting Bilston, in Staffordshire.

The number who died in	Plymouth, being		800
,, ,,	Devonport ,, ...		197
,, ,,	Stonehouse ,, ...		137
	Total.....		1134

The PRESIDENT then said, great attention has been paid here of late to the general health of the towns, by removing cess-pools, improving the drains, augmenting the supply of water, and other means. There is a *sanitary* establishment or quarantine kept up in the port, and there are *sanatory* institutions in the form of hospitals, but the greatest *sanitary* step taken to improve the public health, is the work now in progress for removing the dead from the living. The cemetery will be found to do greater good to the surviving population than any other measure. When we consider that eleven or twelve hundred persons may be buried in the heart of our town, and in the midst of a dense population, in one year, or that eight hundred, as in the cholera, were buried in three months, and that the decomposition of these dead bodies may be washed by the rains into the different wells and drinking places of our towns, we cannot wonder at sudden eruptions of disease, or that a pestilence walks in the midst of our homes. The Plymouth cemetery is calculated to remove the greatest source of disease perhaps from our towns. It is formed without the precincts of the borough in a sequestered vale, with a streamlet meandering at its foot, carrying at once into the ocean all seeds of contamination that may be generated from the decomposition of the dead.

Of the institutions, Dr. Butter said he could only give a succinct account. He began first by alluding to the Athenæum, in which they were assembled, and for the use of which his thanks were tendered to the proprietors. It was built in 1818, and opened in 1819 by Foulston, the architect. Its architecture was Grecian, its portico and columns Doric, like the Temple of Theseus, at Athens. The entablature had triglyphs and metopes, with casts of Apollo, Venus de Medicis, and figures of Castor and Pollux, Æsculapius, Hygeria, and others.

The Plymouth Dispensary was begun in 1798, at the Guildhall, and removed in 1804, after eleven years. The present building was erected in 1809, chiefly owing to the late Mr. Charles Yonge's munificent legacy of £1000, on which the duty of £100 was paid by his executor, the late Rev. Duke Yonge. There were two physicians, four surgeons, two paid apothecaries, a dispenser, matron, collecter, and two dentists, attached to this institution, which relieved from 1500 to 2000 patients annually. There was also a Public Dispensary at Devonport, of which he could get no report. The Plymouth Royal Eye Infirmary, established in 1821, was proposed by himself, in an address which was afterwards published for its benefit. In this measure he had been very ably seconded by Mr. now Dr. Moore, with whom he had ever since co-operated. The number of patients who had applied for relief, during the 27 years, exceeded 18,000, of whom nearly 1000 had derived the advantage of bed and board in the house. It had been always well supported. There was also a Lying-in Charity for the relief of poor married women; but there was no Asylum nearer than Plympton. The South Devon and East Cornwall Hospital was established in 1840, about eight years since. It was almost surprising that in a population of 100,000 persons, a public hospital should have been so long wanted, and be still cramped for want of funds. The last year's report showed that 229 patients were admitted, of whom 68 were for accidents, and that 10 underwent operations. There were about forty beds only at present. The medical staff consisted of two physicians and three surgeons. But there was no room for a museum or the delivery of lectures. Mr. Cross, whom they had just seen, underwent amputation at the hip in this hospital.

The Plymouth Medical Society was established in April, 1794, about 54 years since, and was proposed by the late Mr. Samuel Fuge. It consisted of fifteen members and twelve associates. The members met quarterly, and dined in turn at each others' houses. Ten members or two-thirds must be present at elections. The shares were transferable, and the books were kept at the Dispensary. That might truly be called a Conservative Society, since it had undergone no important alteration for fifty years, and was formed when neither the population nor the medical practitioners were half so numerous as at present. The affairs were conducted by a treasurer, secretary, and librarian, the two former being filled by Dr. Cookworthy, who manages them with great satisfaction. There was also the Western Medical and Chirurgical Society, of which he had been the President from 1824 to 1832, when the cholera appeared, and broke down his own health, killed some, and drove away other members, so that this society, like the fatal disease, died a natural death.

The Royal Naval Hospital, at Stonehouse, was worthy of their notice. The buildings extended over an area of 24 acres. It was begun in 1762, and remodelled in 1798. From 1810 to 1815, January 1st to December 31st, 48,452 passed through it, averaging

9690 a-year for five years. Two men emanated from this hospital, who attained the highest honour ever allotted to medical men in England,—viz., Sir William Knighton, who was secretary to George IV., and Sir Stephen Hammick, Bart., known to the profession by his work on "Amputations." The Military Hospital, at Stoke, might also be worthy their notice, although few patients were there at present. The most memorable circumstance connected with the Military Hospital in his time was, that the first successful amputation at the hip-joint was performed by Mr. Brownrigg, in 1812, on a soldier, whom he had seen.

From places he went to persons, and first, to the dead, or those who still live by their works, remembering "*Nil nisi bonum de mortuis.*" Dr. John Huxham, F.R.S, died in the year 1768. He published many works, chiefly in Latin, on medical subjects. 1. Observations on the Air and Epidemic Diseases, from 1728 to 1768. 2. On Devonshire Colic. 3. A Register of the Weather for Thirty Years. 4. On an Enormous Omentum, weighing 16lbs. 5. On a large Calculus. 6. On Fevers and Malignant Diseases, for which his tincture of bark was recommended. 7. On Small-Pox, now happily banished by vaccination, on Pleurisies, and other diseases. Mr., afterwards Dr. Mudge, to whose memory a monument is erected in St. Andrew's Church, was a medical practitioner in Plymouth, where he died in 1793. He was well-known to the profession by his inhaler, which was much used at that time for the cure of catarrhous cough. He usually directed twenty inspirations of vapour arising from bark, opium, and paregoric, three drachms of each dissolved in boiling water. It appears that he treated pulmonary diseases by scapulary issues, into which were introduced fifty or sixty peas. He employed gum ammoniacum and laudanum to relieve cough, and thought well of pitch plasters to the skin. He wrote on compound fractures and on the vis vitæ, and published the case of a man, whose leg was seriously fractured, and left for seventeen days wrapped up in blood and balsam; his recovery was perfect. Dr. William Woollcombe was a physician at Plymouth, distinguished for his urbanity and caution. He died on the 23rd of May, 1822, of gangrenous erysipelas, aged 49, and was buried at Plympton St. Mary Church. Westmacott's monument to his memory, revised, it is said, by Canning, may be seen in St. Andrew's Church. He wrote an essay on the frequency and fatality of consumption. About the middle of last century, there lived a Dr. Spry at Plymouth, who described the case of a patient who allowed melted lead to pass into his stomach, during the burning of Rudyerd's lighthouse, at the Eddystone. The man died after many week's suffering, and the consolidated lead, weighing nearly half a pound, was taken from his stomach. Dr. Spry transmitted the account to the Royal Society of London, who refused its insertion in their "Transactions," until his testimony was corroborated by Dr. Huxham and others, for veracity; whereupon he instituted experiments, by pouring melted lead down the throats of fowls and dogs, and taking it out in a solid form, after the animals had been killed. For these cruelties he acquired the censure of many persons, who in these days might have brought him up by the Society instituted for the prevention of cruelty to animals.

From the dead he went to the living, remarking, that by speaking well of them, he might excite envy, without conferring fame. There was, however, a connecting link between the living and the dead, in Richard Dunning, Esq., of Stoke, who was 87 on the 13th of March last. Mr. Dunning was one of the five practitioners, who met at the Globe Tavern, in April, 1794, and formed the present Medical Society, and is the only survivor. He obtained a large and lucrative practice for a period of nearly sixty years, and for some time had retired, full of honour, respectability, and wealth. His mind was still imbued with the ardor medicinæ; and his intelligence, vivacity, and love of profession, were in full force, although he was blind from cataracts. His minutes on vaccination, 1804, and correspondence with Drs. Jenner and Baron, were too well known to medical readers to require any comment from him.

After enumerating several places worthy of the attention of visitors, and referring particularly to the Dockyard, Dr. Butter continued,

They might remember, perhaps, that a most fatal epidemic disease broke out here during the year 1825, and that he had collected and published the cases in a work, entitled "Irritative Fever." Some of the reviewers who reported favourably of this book, questioned his so naming this disease, which was essentially "erysipelas." It was certainly traumatic erysipelas, or erysipelas phlegmonodes, in many instances, but not in all. In others it was simple erythema; and in Dr. Bell who died, there was scarcely blush enough to be called either erythema or erysipelas. It was, therefore, a fever, and the character of that fever was not inflammatory, because bleeding was not the remedy; but, on the contrary, an injury. It was a fever of irritation, and not inflammation; and therefore he called it "Irritative fever." Men could not cut, scratch, bruise, puncture, or injure their skin in any way, without seeing the wounded parts fester, or refuse to heal in the ordinary manner. That shewed weakness or want of power in the parts, and also in their constitutions, which required support rather than depletion. They had seen to-day an instance of a man who had recovered after losing one-fourth part of his body, but several had lost their lives at Devonport, in 1825, from the slightest injuries done to their skins.

There was one other circumstance connected with the Dockyard, and he had done. His respected neighbour, Sir William Snow Harris, had kept there a register of the barometer and thermometer for ten years, every hour in the day and night, and also an anemometer for three years, registering the winds. The result had been published in the "Transactions of the British Association," to which he referred them. Sir William Harris had also invented lightning conductors for their ships of war, and had received from Government a title and pension of £300 a year, besides handsome presents from the East India Company and the Russian Government. He mentioned these things because

Sir William was bred a Surgeon, and was a native of Plymouth.

He had now only to thank them for their forbearance in allowing him to infringe one of their rules, which said that, "no long or elaborate paper" should be written, but he would observe the others by maintaining the honour and respectability of the profession, as much as in him lay, by keeping up their friendly intercourse, and by promoting harmony and good feeling, for the great and common object of their meeting—viz., the health and welfare of mankind.

The following resolutions were then agreed to :—

Moved by Mr. Fuge, and seconded by Dr. Cookworthy, "That the next Annual Meeting be held at Exeter."

Moved by Mr. Swain, and seconded by Mr. Fuge, "That Dr. Pennell, of Exeter, be President-Elect."

Moved by Mr. Kerswill, jun., and seconded by Mr. Square, "That Dr. Kingdon, of Exeter, be re-elected Secretary."

Moved by Mr. Fuge, and seconded by Mr. Pridham, "That Dr. Budd, Exeter; Mr. R. C. Price, Lympstone; Mr. T. Cann, Seaton; Mr. Wm. Woodward, Honiton; and Mr. J. F. Symes, Axminster, be the new members of the Council, in the room of those who retire according to Rule 5,—viz., Mr. Ward, Mr. Lanyon, Mr. Empson, Mr. Spettigue, and Mr. McKenzie."

Proposed by Mr. Pridham, and seconded by Dr. Kingdon, "That the best thanks of this meeting be given to Dr. Butter, the President, for the comprehensive and excellent address which he has delivered to this meeting."

Dr. Butter then introduced Mr. Cross, whose right thigh was amputated at the hip-joint two years since by Mr. Whipple, and whose thigh-bone lay on the table, with many other curious and valuable preparations, furnished by himself and Mr. Fuge. These preparations were illustrative of diseases of the bones, and among them was a specimen of union within the capsular ligament of a fractured neck of the thigh bone. Fine specimens of diseased heart and arteries, lungs, liver, kidneys, and other parts, were shown, including the gall-bladder of a patient who had, many years before his death, discharged thirty-six gall-stones; some beautiful preparations of diseased eyes, one in which a shot had been lodged for six years and a half, and two others with that rare disease, the sclerotic staphyloma; two magnificent specimens of diseased duodenum, with the pancreas and its ducts, and the gall-bladder annexed, &c.

Mr. Swain read the history of a gentleman who died of a ruptured aorta; the specimen was exhibited, and drew forth an interesting discussion.

Mr. Pridham exhibited a drawing of dilatation and rupture of a child's heart.

Dr. E. T. Roe read a paper on "Empyema;" a patient through whose left side an aperture had been made into the chest, and a quantity of matter discharged, was exhibited to the meeting.

Mr. Square made a statistical report of the operations and important accidents which had occurred at the South Devon and East Cornwall Hospital, during the last eight years.

Mr. Fuge exhibited the heart of a soldier, who was shot at Corunna in 1808, and lived fourteen days afterwards, long enough for him to come to England, with the ball in it. There was another instance of a soldier who had lived forty-four hours after having shot himself through the heart. The President also showed another preparation made thirty-eight years since, of a heart in which the semilunar valves had burst, probably some time before death.

Dr. Soltau offered some observations on the cholera, which excited discussion, but it did not appear that anything new was elicited respecting the treatment of that unmanageable disease.

Dr. Cookworthy related some cases of asthma, which had been much relieved by inhaling the vapour of æther poured into hot water.

The President drew attention to the duality of certain diseases, and referred to certain accidents which had occurred in his own practice. He knew a boy who had dislocated both hips at one time, the head of one bone being thrown forwards and the other backwards, owing to his falling off a cart; both were reduced, and the boy recovered the perfect use of his limbs. He also knew a little girl who had scrofulous disease in both hip-joints, at the same time; also a lady who had undergone an operation on each side for strangulated hernia. She still lives and enjoys health.

With these observations the business of the day was terminated. The gentlemen afterwards dined together at the Royal Hotel, Dr. Butter occupying the chair, and the evening was finished at Mr. Swain's, at Devonport, when the members were gratified and instructed by witnessing several valuable microscopical demonstrations.

Foreign Department.

CLINICAL MEDICINE AND SURGERY IN THE CONTINENTAL HOSPITALS.

Inflammation of the Superior Lobe of the Right Lung.—The fatal issue of this circumscribed inflammation, and its peculiar symptoms, induced M. Harvez to institute anatomical researches on the subject. At the very onset of the disease the patients present an extraordinary degree of prostration, great paleness, general refrigeration, disturbance of the intellect, a very small pulse, nausea, sickness, and diarrhœa. In general considerable pain, both above and beneath the clavicle, is complained of; cough and expectoration are insignificant. All these characteristic symptoms existed so plainly in a case admitted into hospital in July, 1847, that the diagnosis was not for a moment doubted, nor the fatal prognosis uncertain. The patient died on the 13th day; and on dissection the superior lobe of the right lung, in a state of condensation, was found to have interfered considerably with the circulation of the blood in the cava descendens, and in the right auricle: both contained fibrinous coagula. It is to this impediment to the venous circulation that Dr. Harvez refers the greatest part of the peculiar symptoms observed, viz., the livid hue of the countenance, the cerebral

disturbance, the nausea, and serous diarrhœa. The peculiar nature of the pain is accounted for by Dr. Harvez by the pressure exercised by the inflamed lung upon the par vagum; and he concludes by stating that the apparent state of collapse, and smallness of the pulse, should not prevent the physician from having recourse to energetic antiphlogistic measures for the purpose of liberating the circulation and subduing inflammation.—*Monthly Journal.*

Hæmoptysis.—M. Guerard frequently makes use of the external application of cold water to the chest in obstinate cases of pulmonary hæmorrhage, as in the following case:—A young woman, aged 20, was received into the Hotel Dieu, in a state of great danger from hæmorrhage, which had resisted all treatment for several days. M. Guerard ordered the thorax to be enveloped in towels dipped in cold water, and mustard plasters to be applied at the same time to the lower extremities. The hæmoptysis ceased as by enchantment, and did not recur during the several weeks she remained in the hospital. Her general condition improved much, and symptoms of commencing phthisis disappeared.

General Prophylaxis.—The same physician professes to be able to prevent the occurrence of many severe maladies, by the exhibition of sulphate of quinine as a prophylactic, in doses of two grammes (dr. ss.) during two or three successive days. In this manner he is said to cut short or to prevent the development of typhoid fever, erysipelas, &c.

Loose Cartilages.—A man having been admitted into M. Velpeau's wards for the treatment of arthritis caused by the presence of a loose cartilage in the knee-joint, occasioned some remarks from the professor, of which the following is an abstract:—"The formation of these loose cartilages has been referred to various causes. For a long time they were supposed to result from the detachment of the cartilage fron the articular surfaces. On two occasions, M. Velpeau ascertained the correctness of this opinion, but it cannot be entertained in all cases. Sir A. Cooper and Bérard believed them to be formed outside the synovial membrane, from the deposition of plastic lymph. Another cause might be found to reside in the thickening and inflammation of a fold of the synovial. M. Velpeau had shown, that a fourth origin might be traced to hæmorrhage within the joint, the liquid part of the blood being absorbed, and fibrinous concretions remaining afterwards. Whatever their cause, the prognosis of these loose cartilages must always be of a reserved nature—their presence exposing the articulation to frequent inflammation, and their removal being often followed by the most fatal consequences. The perils of extraction have, however, been greatly diminished by the subcutaneous operation proposed by M. Goyran, a surgeon of Aix. That gentleman operates in the following manner:—Through a fold of the skin a narrow-bladed knife is introduced into the joint, and the foreign body is forced through this aperture into the cellular tissue, whence it is removed, after eight or ten days, by a simple division of the skin, the wound of the synovial membrane have been allowed time to heal. M. Velpeau had twice operated successfully in this manner. In the case which led to the present remarks the loose cartilage was attached to the synovial membrane by a pedicle, which increased considerably the difficulties of the operation."—*Monthly Journal.*

Fracture of the Olecranon.—M. Harvez de Chegoin notices the great difficulty usually experienced in keeping the fragments in apposition in this fracture, and offers the following case as illustrative of his method of overcoming the embarrassment:—

A woman, aged 65, fell violently on the staircase, and fractured the left olecranon, a little below its middle. I did not see her till the next day; there was then considerable swelling above and within the articulation down to the middle of the forearm; while the point corresponding to the fracture was scarcely swollen, and the skin then preserved its natural colour, which gave reason to suppose that the fracture, though caused by the fall, was the result not of direct violence, but of muscular action.

The fragments were separated by an interval of nearly half an inch; they were easily brought together by extension of the forearm and pressure on the upper portion, but an involuntary movement of flexion immediately separated them.

The contusion of the arm and forearm had been violent. The swelling and ecchymosis increased on the following days, and extended to the hand. The pain became more severe on the eighth day, and the cold lotions were exchanged for emollient poultices. The joint, however, remained free from this tumefaction, which confirmed my view of the manner in which the fracture had been produced, and allowed me to see what took place between the two fragments.

On the eighth day the interval between them was filled by a soft substance, which increased in quantity on the succeeding days, so as to rise above their level behind. It had become more liquid, and afforded an evident sense of fluctuation.

On the fifteenth day it was much reduced, and allowed the finger to be placed between the fragments. By this time the pain and swelling of the forearm had nearly disappeared, but the ecchymosis remained down to the wrist, with a degree of induration of the soft parts. The forearm till now had been kept on a pillow in the semiflexed position without any apparatus, of which the patient was singularly apprehensive from the recollection of what she had suffered from bandages too tightly applied for a fracture of the clavicle.

The object was now to bring the fragments together without exercising any compression, and at the same time to keep the forearm semiflexed. For this purpose I contrived the following apparatus:—I placed the limb in a hollow-jointed splint, deeply excavated behind, so as to leave the posterior surface of the joint free. At the upper part of this hollow I fixed a piece of elastic gum, about two inches square and a third of an inch thick, by means of narrow tapes passed from within outwards through two holes made on each side. At the two inferior angles were fixed two other tapes, which I also passed from within outwards through two holes bored on each side of the lower margin of the

excavated portion of the splint. I then applied the piece of elastic gum above the upper fragment, and by gently drawing the lower tapes brought it easily into contact with the inferior fragment. Fearing, however, that this pressure might cause some pain, I loosened the tapes a little, satisfied that a slight but continued action would overcome the muscular resistance.

The fragments became gradually approximated, merely taking care to tighten the tapes according as they became relaxed, and at the end of six weeks were so close that the finger could scarcely detect the interval between them. About the thirtieth day I began to give a little passive motion to the joint; this caused a little pain, not in the joint, which all along was free from any inflammatory action, but in the soft parts of the forearm, which for a long time continued indurated by the blood infiltrated in their substance and beneath the integuments, which, after two months and a half had elapsed, retained the yellow hue of old contusions. The patient, however, could execute with facility the fullest movements of flexion and extension.—*Gazette des Hôpitaux*, in *Dublin Medical Press.*

Extirpation of the Velum Palati.—This operation was, according to the Editor of the *Annales de Thérapeutiques*, first performed by M. Blandin, who resorted to the ligature, believing that excision with the bistoury was liable to be followed by dangerous hæmorrhage. That such may be the case is not to be disputed, as death from that cause occurred to a patient operated upon by M. Roux, but that it is not an insurmountable feature of the operation appears from the following case reported by M. Minich, Clinical Professor of Surgery at Padua:—

A man, aged 34, first complained of difficulty in swallowing, in the winter of 1847. He was subsequently admitted into the hospital at Padua, as the subject of polypus of the pharynx; examination, however, proved that it was a much more formidable affection,—namely, encephaloid disease of the velum palati. This part was a quarter of an inch thick, and studded behind with encephaloid tubercles, which were also located in the posterior aspect of the pharynx. The pillars of the fauces and the tonsils were likewise involved, the nostrils were impervious, and the tongue was pushed to the right side. M. Minich at once proceeded to remove the deceased parts by incision, removing first the velum pendulum palati in totality. This was followed by hæmorrhage, for which the actual cautery was used in vain, and the bleeding was only checked by plugging with lint dipped in alum, as is done in severe epistaxis. The remainder of the disease was destroyed subsequently by several applications of the actual cautery, and the man went out cured. (!)

Hydrarthrosis of the Knee; New Variety.—A man, aged 40, of good constitution, came into hospital for a dropsy of the right knee-joint. The disease had existed for two years, and was unaccompanied by pain, or other inconvenience, with the exception of difficulty in moving the limb. The joint was greatly enlarged, tense, and fluctuating. In examining the fluctuation below the patella, an immense number of small bodies were felt to glide beneath the fingers, similar to the touch to the hydatid cysts which are sometimes found in the wrist. M. Velpeau said that he had never seen a case of the kind before, and was doubtful of its being a curable affection. He covered the knee with a large blister, by which the fluid was partially removed, but it speedily re-accumulated under the constant irritation produced by the bodies before mentioned.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS.

This Academy has during the past month resumed the interminable discussion respecting the connection between intermittent fever and certain conditions of the spleen. It also discussed a memoir on the *diseases arising* from the use of lead by M. Legroux, neither of which offer matter of interest.

ERGOT IN RETENTION OF URINE.

M. Allièr read a communication on the use of *ergot in retention of urine.* According to him:—1. Ergot restored contractility to a bladder which has been paralysed by over-distension. 2. It has succeeded when other remedies have failed. 3. It has been equally successful in paralysis of the bladder following apoplexy. 4. It does not exert any beneficial influence over hemiplegic limbs. 5. It is useless in retention of urine from enlarged prostate. 6. The medicine must be given in repeated small doses; but it may amount to a drachm and a half per diem.

[A case illustrative of the good effects of the ergot in retention of urine is related by Dr. Jeffreys, of Liverpool, (now of Shrewsbury,) in the *Provincial Journal* for 1844, p. 44. Dr. Ross, of Cambusmore, in the county of Sutherland, reports a similar case. See *London and Edinburgh Monthly Journal* for January, 1844, and *Provincial Medical Journal*, vol. vij., p. 378. See also Johnson's *Medico-Chirurgical Review* for July and October, 1839.]

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

ACIDITY AND ALKALINITY OF THE FLUIDS.

The only memoir presented to the Academy of Sciences, worthy of notice in the pages of this Journal, is one by M. Andral on the "Acidity and Alkalinity of the fluids in health and disease." The object of the memoir is to inquire whether such fluids as are physiologically acid or alkaline respectively, are capable of being reversed under disease. The author has examined most of the fluids of the body, including the serum of the blood, the sweat, the tears, urine, &c., and has come to the conclusion that their acid or alkaline characters are far more constant than is generally supposed, and thus with the exception of the urine, little or no deviation from the physiological state is impressed by disease.

POOR-LAW MEDICAL CONVENTION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In addressing myself to the meeting, at Bath, as Treasurer to the Poor-Law Medical Officers Committee, I felt reluctant to occupy the time of the meeting, precious as it is, or ought to be, and fear that my appeal, insufficiently expressed, was not properly understood.

It must be manifest that since the great meeting of the Poor-Law Medical Officers, in London, in October last, and the appointment of a Committee to act on their behalf, considerable expenses must have been incurred. Their labours have involved charges for advertisments, printing, stationary, postage-stamps, and the salary of an Assistant Secretary.

You, sir, very kindly and properly give gratuitous insertion to our advertisments in this Journal, and the National Institute favours us with the free use of their office.

To defray the expenses, subscriptions of small sums, chiefly from the Poor-Law surgeons, have been received, including the handsome donation of ten pounds from Mr. Pennington, the President of the National Institute; but when it is considered that papers were to be forwarded to 2914 medical officers of Unions, the correspondence which ensued, with the various items of expense already mentioned, it cannot be matter of surprise that further contributions are become indispensably necessary.

By the statement of the Treasurer's account appended to the report recently issued, there was a small sum in hand, since which, however, the balance of account is on the other side.

The perusal of the report, of which a thousand copies have been printed, with an equal number of the "Address to the Public," which have been reprinted in the Journal, will show that the labours of the Committee have been of no small amount; in fact, much more considerable than is generally supposed. Gentlemen have come up repeatedly from Buckinghamshire, Derbyshire, Staffordshire, and even Lancashire, devoting their invaluable time, and at no small expense, to the object in view.

Those members of the Committee who reside in the metropolis and its neighbourhood, have been able to give a more frequent attendance, still at some expense, and the application of valuable time, and of earnest and patient thought.

Under these circumstances the profession at large would not wish the members of the Committee to be without pecuniary resources to defray the very moderate, but essentially necessary, expenses which will accrue; and it is acknowledged, that not only the Poor-Law surgeons immediately interested, but the whole profession should unite in giving support to the cause, as unquestionably the credit, respectability, and honour, of the whole medical profession, of which we sometimes boast, may fairly be considered as identified in the cause of the Poor-Law surgeons.

The report, in the pamphlet form, with the "Address to the Public," was offered to the acceptance of gentlemen attending the recent meeting at Bath, and I shall be happy to forward copies to those who have not yet seen it.

I shall now be glad to receive subscriptions towards defraying the expenses necsssarily incurred for official purposes by the Committee, by Post-office order, or otherwise, and remain,

Sir,

Your very faithful servant,

THOMAS MARTIN.

Reigate, August 25, 1848.

CORONERS' INQUESTS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I shall be glad if you will insert the following cases in the *Provincial Journal*.

Your obedient servant,

AUGUSTIN PRICHARD.

Bristol, August 23, 1848.

An old gentleman called upon me some time ago labouring under *bronchitis senilis*, to such an extent, that after prescribing for him, I felt much relieved when he was placed in a fly, and taken back to his hotel. The next morning he was found dead in his bed by the porter who had been directed to awake him. An inquest was held, and the porter who found him was called upon to give evidence, as was also a neighbouring medical man, who had been called in, in the hurry of the moment, when the gentleman was discovered to be dead, and who, without having seen him during life,—without any *post-mortem* examination, and in thorough recklessness of all medical etiquette,—helped the jury to arrive at the conclusion that Mr. Prichard had ordered the patient some pills and drops for his cough, and that he was found dead in his bed.

A few days ago I was called about six, a.m., to see a child, which was said to be very ill. The child was dead, and its body nearly cold. From what I could learn by inquiries, I suspected that it had been overlain. An inquest was held, and the jury having looked at the body, determined that the child had died in a fit! In both cases I had left word that I was ready to attend if it was deemed requisite, thinking, of course, that in both, but more especially the latter, an examination of the body was indispensable.

Some years ago, a surgeon of this city died rather suddenly, after a month's confinement to bed, from an accident. The coroner insisted upon an inquest, and took occasion to express his opinion of the great *importance of coroner's inquests*. The two cases which I have just adduced authorize us to conclude, that by these words he merely meant to express, in an abbreviated form, the *importance to the coroner of his receiving his fees for the inquests*; for it was a mere form, no cause of death was discovered in either instance, and any real value of an inquiry of this nature was completely nullified.

There may possibly be some remote advantage in publishing such abuses in medical journals; but it is only to avoid the charge of bringing myself unnecessarily, and in an unprofessional way, before the public, that I do not send these remarks to one of our local papers.

REMARKS ON THE USE OF PETROLEUM IN ASIATIC CHOLERA, AND THE PROBABLE ADVANTAGES OF PHOSPHATE OF SODA AS A REMEDY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Dr. J. Tunstall, of Bath, in the *Provincial Medical and Surgical Journal* for July 12th, states that pure petroleum is a powerful stimulant, and that it owes its stimulating qualities to the large proportion of pure carbon which it contains.

He says that Asiatic cholera is a disease attended with an alteration and decomposition of the vital fluids, an assertion which I am by no means disposed to deny, and that on the authority of Dr. John Davy, there is less carbonic acid in the respired air of cholera patients, than in that of healthy people. The remedial agency of petroleum, therefore, is due to its supplying that element, (carbon,) in which the blood of cholera patients is deficient.

Dr. Tunstall, at the same time that he considers petroleum to be of special benefit, because it contains no element but hydrogen and carbon, administers it with two diffusible stimulants, brandy and ammonia, the latter of which, saving that it is exhibited in the form of carbonate, is devoid of carbon. The analysis of blood in health varies so much, that it is not surprising it should do so in disease. According to Dr. Davy, the venous blood in cholera contains less carbonic acid than in health; and Dr. Stevens says, that "it is a fact that the arterial blood contains less air," by which, I presume, is meant oxygen or atmospheric air. Heller, ("Simon's Chemistry," vol. i., p. 326,) says, that "from the carotids of a man, who died from spasmodic cholera, the blood was of a very dark colour and of a tolerably thick consistency." May not carbonic acid have been present in the arterial blood, in quantity equivalent to its deficiency in the venous blood, owing to its imperfect elimination from the lungs during respiration?—or may it not have been carried off by the serous discharges from the bowels?

Dr. Stevens, in his work on the blood, attributes to the saline ingredients the power of converting black into red blood; and, as in cholera, the saline ingredients are diminished, (for, by the researches of Dr. Thompson, the serum of cholera blood is diminished, and the crassamentum increased, while the alvine discharges consist principally of serum and coagulated fibrin, the serum being much larger in proportion to the fibrin than in the blood,) may not this diminution of the saline matter serve as an important indication to the treatment of the disease; and may not the maintaining of the supply of serum prove more beneficial than the adding of an increased quantity of carbon to the blood, which possibly contains already as much or more carbonic acid than healthy?

The relative condition of venous to arterial blood in this disease is worthy of further investigation. In the different analyses of healthy blood, we find, according to Marcet, it contains carbonate of soda; to Berzelius, lactate of soda, soda, and phosphate of soda, besides other saline ingredients, especially the muriate of soda; while Liebig says that it contains no carbonate of soda, nor free soda, but that it owes its alkalinity to the presence of *phosphate of soda*, and he says, "there is no known salt, the chemical characters of which approach more closely to those of the serum of the blood, than the phosphate of soda, there is none more fitted for the absorbtion and entire removal from the organism of carbonic acid with great facility."

Dr. Stevens having altogether omitted any allusion to phosphate of soda, as an important ingredient in the blood, notwithstanding his doctrine of the saline treatment in cholera, and being apparently unaware that it possesses the value attributed to it by Liebig, is it not probable that the *phosphate of soda* may prove of great benefit in the further carrying out of Dr. Stevens's saline treatment, of the merits of which many practitioners are fully convinced!

The remedial powers of petroleum or native naphtha will soon be made known. The mortality, by the latest accounts from Russia, being so great, as to lead to the supposition either that it has not been generally employed as a remedy, or that it is useless.

I have the honour to be, Sir,
Your most obedient servant,
EDWARD TWINING.

27, Albion Street, Hull, July 27,

EFFECTS OF THE DIRECT APPLICATION OF CHLOROFORM TO A DECAYED TOOTH.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The following brief account of the effects of chloroform, and which I should have forwarded some time since, but have been prevented by many circumstances, may not be considered unworthy of the space which it will occupy. The case is a most simple one, and the relief was (if I may so term it,) *quite magical*. I have neither read nor heard of its application in any similar case, much as we have heard of its utility in dental surgery, so far as the avoidance of pain during the drawing of the tooth is concerned, and all who require this operation would, I opine, very much prefer this "nectar" of medicine, if it preserved to them a useful tooth, and the symmetry of their mouth. The following is my case:—

"A gentleman who had suffered often and severely from a decayed tooth, and which he was very loth to part with, but which he thought must be extracted,—asked my opinion as to the propriety of inhaling chloroform during its extraction. It then struck me—why not try the *immediate* application of this fluid as a styptic? I proposed it; he acceded; and I consequently ventured to poach on the dentists' preserves; and having cleared out as much as possible of the decayed matter, (an operation attended with excruciating pain,)

I moistened a small piece of jeweller's softest wool with six drops of the chloroform, and put it into the hollow tooth. In a shorter space of time than I write the words "the pain was gone." My tale is told, and I have only to add, that creosote and other usual remedies had been frequently tried without any beneficial results. Hoping that this will not prove an isolated case,

I am, Sir,
Yours faithfully,
BENJAMIN BARROW.

Ryde, Isle of Wight,
August 31, 1848.

THE DINNER, AT BATH: DR. WOOD'S SPEECH.

We give the following corrected report of the observations made by Dr. Wood, at the Dinner of the Association, at Bath. The position which Dr. Wood occupied at the meeting, as deputed from the Medical Association of America, must render whatever fell from him on that occasion of deep interest, not only to the members of the Association, but to the profession generally:—

"Mr. Chairman and Gentlemen,—It is with emotions that I fear may prevent the expression of all I feel on this occasion, that I rise to thank the present company for the honour they have done me, and more especially for the honour they have done my country through me. Science is universal and everywhere identical. Born of the necessities and faculties of our nature, and devoted to the good of mankind, it is one in its origin and aims, and should be cultivated by all in a spirit of brotherhood. If it be true of the great system of the sciences, that they are held together by one pervading principle of union, it is still more true of them in their subordinate relations; as, in the solar system, though the several planets are united in one great whole, each is influenced in its own constitution by a yet stronger force of attraction. Thus, as cultivators of science in general, we have a certain connection, but a still closer one as medical men; and there is yet an additional tie between the profession here and in America. We have the same origin, the same language, to a great extent the same literature; and draw all our knowledge (our professional knowledge, I mean,) from almost the same sources. We are the children of one common mother, and should therefore feel as brothers. Standing here as the representative of the profession in America, I may say, as the representative of the intelligence of America, (for the feelings of the medical men of a country may be taken as a standard of those of its intelligent inhabitants,) I may venture to say that, in our land, there prevails almost universally among the well-informed a kindly disposition towards the mother-country; and it should be our anxious wish, upon both sides, to cultivate this friendly feeling, and to cause it to flow from the intelligent ranks, down, through all gradations of knowledge, to the very humblest in society. With the best properties of several races in our character, as we have their blood in our veins, we, the English and Americans, constitute, I think, the finest race of men upon earth. With the impulsiveness of the Welshman or Celt, the steadiness of the German or Saxon, and the energy and determination of the Norman, we are destined to go on, as we have begun, filling the waste places of the globe; and, unless interrupted in our progress by the strife of ambition, or false notions of interest, we shall probably continue to advance, until the whole earth becomes impregnated with Anglo-Saxon sentiment, Anglo-Saxon institutions, and Anglo-Saxon religion; and such a consummation is to be most earnestly desired.

Medical Intelligence.

THE CHOLERA.

The cholera appears to be gradually subsiding at St. Petersburgh and Moscow, but we understand it is still raging in several places in the interior of Russia. It is also now prevailing at Abo, in Finland; in the province of Gallicia, in Poland; in Berlin, and at Stettin, in Prussia. In Egypt and Asia Minor it has been making fearful ravages. At Aleppo, between the 17th and 19th of July, nearly a thousand persons died from the disease. The Vienna papers of the 17th and 18th of August state that the disease is exceedingly malignant at Riga, the deaths being 100 daily out of a population of forty to fifty thousand.

SOCIETY OF APOTHECARIES.

Gentleman admitted Licentiates Thursday, August 17th, 1848:—Draper Mackinder, Barton-under-Needwood; George Robert Cubitt, Norwich; Frederick Charles Cory, London; John Seager Gundry, London; George Grayling, Sydenham.

OBITUARY.

Died, August 7th, at Stockholm, aged 69, the Baron Berzelins, Perpetual Secretary to the Royal Academy of Sciences, at Stockholm, and Foreign Associate of the Institute of France.

August 21st, at Paris, aged 43, M. Hamont, Founder and late Director-General of the Veterinary School of Abou-Zabel, near Cairo.

BOOKS RECEIVED.

Contributions to the Pathology of the Kidney. By William Gairdner, M.D. Edinburgh: Sutherland and Knox, 1848. 8vo. pp., 54.

Arguments against the Indiscriminate Use of Chloroform in Midwifery. By S. William J. Merriman, M.D., Cantab., Licentiate of the Royal College of Physicians, &c. London: Churchill. 1848. 8vo. pp. 27.

Oratio ex Harveii Instituto in Ædibus Collegii Regalis Medicorum habita Die Junii xxiv; 1848. A. Francisco Hawkins, M.D., Coll. Reg. Med. Lond. Socio et Regestario. London: Churchill. 1848. 4to. pp. 27.

Report of the Council of the National Institute of General Practitioners in Medicine, Surgery, and Midwifery, on the Present State of the Medical Reform Question. London. 1848. 8vo. pp. 84.

TO CORRESPONDENTS.

Communications have been received from Dr. Blackmore; Mr. A. Prichard; Mr. T. Martin; an Irish Apothecary; Mr. Cotton; Mr. Barrow.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

A CLINICAL LECTURE.

Delivered at the Leeds Public Dispensary.

By J. D. HEATON, M.D., Senior Physician to the Dispensary.

Hypertrophy and Dilatation of the Heart, with diseased Aortic and Mitral Valves; Dropsy; Albuminuria.

Wm. Hardy, admitted into the Leeds Dispensary, in January, 1846, aged 19. A stout lad, of middle size, face bloated and of a deep purple-red from venous congestion. He has been subject to palpitation for several years, but without cough; his health has been so bad that he has not been able to work for some years. For the last nine months he has been much worse than usual, suffering much from palpitation and dyspnœa. He has already had much treatment: he has been salivated, and has had frequent applications of leeches and blisters, and likewise a seton over the cardiac region. Latterly, œdema of the legs had supervened, and he has been incapable of any exertion. The immediate cause of his admission to the Dispensary was his having fallen down in a fit, insensible. For this he received immediate treatment by leeches applied over the heart, and purgative medicines. I first saw him the following day.

Symptoms.—The face was purple and bloated; body and legs much distended with dropsical effusion; feet cold; breathing much oppressed; pulse small, feeble, very irregular; tongue large, purple, thickly loaded with a yellow moist fur; urine very scanty, not more than from one to two ounces per diem, of a dark brown colour, free from albumen, but containing a copious pink-coloured deposit, which examined under the microscope was seen to be partly amorphous, (lithate of ammonia,) partly in crystalline grains, (lithic acid;) bowels open; some tenderness and occasional pain over the region of the liver.

Physical Signs.—The front of the thorax was rounded and very prominent; on applying the hand over the heart, an irregular tumultuous motion was felt; the impulse diffused but without much force, most perceptible near the left edge of the sternum, two inches below the nipple; extensive dulness of stroke-sound over the heart, reaching from two inches above, to the same distance below, the left nipple; and in breadth, from the right edge of the sternum to two inches to the left of the left nipple. The first sound of the heart obscure, but accompanied with a loud blowing murmur, loudest over the middle of the sternum, which might be traced along the course of the aorta; and heard likewise, but fainter at the apex of the heart; no second sound audible. Breath-sound heard distinctly down to the base of the lungs behind, and free from muco-crepitation. Extensive dulness over the region of the liver.

Diagnosis.—Hypertrophy with dilatation of the heart; obstructive disease of the aortic valves, and regurgitant disease of the mitral; no effusion into the pleural cavity.

The treatment was the common diuretic pill of squills, digitalis and blue pill, a diuretic saline mixture with sulphuric æther; and a large blister between the shoulders. Under this treatment the respiration was soon relieved, and the urine became more copious, at the same time losing most of its sediment, but remaining high-coloured, of sp. gr. 1016. The pills were continued, the æther omitted from the mixture, but a saline added, together with the iodide of potassium and Vinum Colchici to keep up a free action on the liver, and kidneys, and intestinal surface. Under this treatment all dropsical effusion was soon removed, the urine assumed a more natural character, and the stools became more bilious, at the same time that the general symptoms were all relieved; there was no palpitation; the pulse became firmer and less frequent, the tongue cleaner and less purple, and the face less congested.

A more tonic treatment was subsequently adopted, and the patient continued for some time in a more comfortable state than he had experienced for long previously.

In the middle of February there was no marked change in the general symptoms, but the urine again contained a pink sediment; though still moderately abundant, it was high coloured, rather dense, of sp. gr. 1025, and was now decidedly albuminous; it was so abundantly charged with urea, that without any concentration, on the addition of its own measure of nitric acid, a copious crop of crystals of nitrate of urea were deposited. A repetition of the physical examination only confirmed the results of the former one; the second sound still remained inaudible.

The patient continued, on the whole, much better till March, having only one or two slight relapses, of which the chief symptoms were increased palpitation and more scanty urine. He was discharged for the time, but with an injunction to apply again should he become worse.

In July this patient applied again for admission.

He had been out of Leeds and was somewhat better for a time; but had latterly considerably relapsed. Most of the symptoms were similar to those which had presented on his previous admission—face bloated and purple; body anasarcous; tongue large, and purple; urine very scanty and high-coloured, containing much pink deposit of lithate of ammonia, mixed with crystals of lithic acid; considerable pain and tenderness over the liver, and likewise at the pit of the stomach; palpitation and dyspnœa as usual. The result of the physical examination was likewise similar to that previously obtained; one prolonged, blowing, systolic murmur was heard, commencing with the impulse but prolonged beyond it, over the base of the heart, and along the aorta, but likewise at the apex, though less distinct; there was no second sound.

Saline purgatives and diuretics, with small doses of blue pill, squill, and digitalis, considerably relieved him; and in a few weeks he was in his ordinary state of health. He continued much in the same condition during the month of August, and was sometimes able to walk out for a short time; but on the 9th of September, after his mother had brought him his breakfast in bed, as usual, on returning to him in a short time, she found him on the point of death; he gave one or two gasps while she stood by him, and then breathed no more.

The *post-mortem* examination was made ten hours after death. The face had become pallid, but was still bloated; there was evident fluctuation of the abdomen, and the legs were œdematous. The cavity of the thorax contained a large quantity of clear serum. On removing the anterior walls of the chest, the heart was seen of great size, filling up all the front of the cavity, the lungs being pressed backwards, so as to be nearly out of sight. The pericardium contained much fluid, but both the serous surfaces were smooth and healthy, and there were no adhesions. The cavity of the left ventricle was much dilated and its walls were nearly an inch in thickness anteriorly; the septum between the ventricles was less than half this. The musculi papillares were hypertrophied to the thickness of a man's finger; the *columnæ carneæ* on the inner surface of the walls were large and unusually prominent. The membranous portion of the mitral valve was much enlarged, but not otherwise unhealthy; the orifice was dilated so as to admit of four fingers. On passing the finger upwards towards the commencement of the aorta, it met with an obstruction at the aortic valves; this was owing to the free margins of the semilunar valves having become adherent, so as to form a flat membranous septum at this point; a round opening being left in the centre, too small to admit an ordinary quill. The membrane of the valves was not indurated nor thickened. The commencement of the aorta itself was contracted. The cavity of the left auricle was much dilated; its walls were thin and membranous. The right cavities of the heart were likewise dilated; the right ventricle was considerably hypertrophied, but to a much less extent than the left. The tricuspid valve was healthy, but of an unusual form, consisting only of two segments, like the mitral valve. The cavities of the heart contained much black clotted blood. The heart when quite free from blood weighed one pound and a half. The lungs appeared free from disease, though unduly compressed by the large heart and the serum effused into the pleura, but were neither congested nor infiltrated with serum.

In the abdomen, the liver was much enlarged, projecting considerably below the margin of the ribs; the colour was a dark brownish purple, the surface uneven, with numerous projections, of an irregularly rounded form, about the size of a split pea; the substance of the liver was dense and hard, the colour of a section similar to that of the exterior, but mottled with lighter-coloured spots upon a dark ground. The kidneys were larger than natural, of a dark colour, the substance hard and firm, but not granulated. The thickness of the cortical structure had a proper proportion to that of the medullary part of the kidney.

I think the above case interesting both as presenting an unusual form of valvular disease, and as showing how well the physical signs served for diagnosis during life, and how consistently they are explained by the appearances observed in the *post-mortem* examination. The previous history gives no very satisfactory account of the origin of the cardiac disease. It may be a question whether the morbid condition of the aortic valves could possibly be congenital; there was not merely the obstruction caused by this, but an evident contraction in the walls of the aortic aperture. Where this condition exists congenitally, it is usually accompanied by some continuance of the fœtal communications between the right and left sides of the heart; but this was not found in the present instance. On the other hand there seems a difficulty in supposing inflammatory adhesions to be formed between the margins of valves, which are separated from each other by the current of blood with each ventricular systole; besides which, an endocarditis, causing such adhesions, might be expected to have left other consequences, such as thickening, induration, contraction, &c. But the membrane which formed this curious septum was smooth, soft, and translucent, with a round aperture in the centre, as though cut out with a punch. Dr. Hope, in his work on diseases of the heart, relates a case of aortic obstruction somewhat similar to this, with an engraving of the appearance of the aortic valves, (case of Hedgley, p. 564, 3rd edition,) which was "manifestly referable to endocarditis ten weeks before death;" but in his case the valve was contracted by fibro-cartilage, and the aperture is represented considerably larger than that of the preparation from the case above narrated. Besides this case of Dr. Hope's, I remember no record of any other with similar disease of the aortic valves. I have seen described, and likewise myself met with, a condition of the *mitral* valve which may be analogous to that of the aortic valve in the case under consideration; the margins of the two segments of the valve have adhered through the greater part of their length, thus forming a funnel-shaped projection into the left ventricle; and this condition may exist without thickening or contraction of the membrane

of the valve. There seems almost as great an *a priori* objection to the probable occurrence of such adhesion in the case of the mitral, as of the similunar, valves.

Besides this condition of the semilunar valves, there was no other appearance of previous inflammation, either in the internal or external membrane of the heart, the effusion into the pericardium being merely dropsical. The other morbid changes in the condition of the heart are clearly referable to the aortic obstruction. The resistance here offered to the escape of blood from the left ventricle, would necessarily cause more forcible contractions of the heart to effect its evacuation; these, by their continuance, must cause hypertrophy, but being still insufficient to counteract so great an obstruction, the tissue must gradually yield, and thus dilatation follow. These effects would take place first, in the left side of the heart, where their cause is situated, and then extend to the right side, the resistance to the circulation being communicated through the vessels of the lungs; besides which communication through the pulmonary veins and arteries, the excited action of the one part of the heart must be communicated to the other through its own tissue, the muscular fibres of the two sides of the heart being (as Dr. Williams has pointed out,) so blended with each other, that one cannot be aroused into increased activity, without the other sympathizing likewise in the excitement.

The "fit" which led to this patient's admission to the Dispensary was probably caused by extreme venous congestion of the brain; the bloated and purple appearance of the face on the following day, when I first saw him, showed how much venous congestion still existed. Such a state is a necessary consequence of so serious an obstruction, as existed here to the exit of the blood from the left ventricle, and of a dilated and permanently patent state of the mtiral valve, the blood being constantly thrown back through the pulmonary vessels upon the right side of the heart and the venous system. There is another not improbable explanation of the fit,—viz., that it was a state of syncope, consequent upon a partial arrest of the heart's action due to its congested and overloaded condition. It is to this latter cause that I attribute his sudden death some months subsequently. Not having seen the patient at the time, I am unable to decide confidently between these two explanations, but there seems to me some objection to the latter, in the doubt whether the patient could have probably been aroused from the state of syncope so caused, before it had terminated in death.

The diagnosis which I have given above of the condition of the heart, is what I have written down in my notes of the case, after making the examination; therefore, long previously to his death. It is that which naturally suggests itself from the physical signs detailed, which are still further explained by the appearances found upon actual inspection of the heart after death. Hypertrophy of the heart was implied by the unnatural prominence of the front of the thorax, the extent over which the movements of the heart were perceptible, the extent of the dulness of the stroke-sound, and the dull character of the first sound of the heart. The dilatation was rather a matter of inference, from the great external size of the heart and feeble impulse, and as a probable result of the valvular disease. Placing the stethoscope over the base of the heart, a blowing murmur was heard accompanying the first sound, which might be traced upwards along the course of the aorta. This sound accompanying the first sound of the heart, which is contemporaneous with the ventricular systole, must be caused by the current of blood out of the ventricle; and its being audible along the course of the aorta, implied that its seat was at the commencement of this vessel,—that is, at the aortic valves, where any roughness of surface, irregularity of form, or contraction of calibre, may serve to throw the blood into sonorous vibrations. But this morbid sound was likewise *prolonged*; implying that the vibrating current of blood, by which it was caused, passed slowly out of the heart, as though meeting with some obstruction.

Upon these observations then, was founded the diagnosis of obstructive disease of the aortic valves. When we see how great the obstruction really was at this point, we cannot help wondering that the circulation could be carried on at all, with that degree of efficiency necessary to continued existence; the whole blood of the body having, in each circulation, to pass through an aperture less than an ordinary quill. A small and feeble pulse was inevitable in such a condition of the valve: and its irregularity which we have likewise mentioned, accompanies all forms of extreme valvular disease. It is only in extreme cases of aortic contraction, Dr. Hope says, that we find the pulse small, weak and irregular. But another murmur was likewise heard accompanying the first sound of the heart, and which might be traced in an opposite direction, viz., downwards, to the apex of the heart, where it was most distinct. Murmurs heard in this position have their origin in the auriculo-ventricular valves, (most usually the mitral,) the sound being conducted by the musculi papillares and the walls of the ventricle to the apex of the heart, where it strikes against the parietes of the chest at each systole. A murmur in the mitral valve accompanying the contraction of the ventricle, must be owing to the escape of blood backwards out of the ventricle into the auricle, in consequence of the imperfect closure of the valve. Thus was established the second part of the diagnosis of the valvular disease,—viz., mitral regurgitation; and this was shown in the *post-mortem* examination to be the result of the general dilatation of the walls of the ventricle, by which the auriculo-ventricular opening was so much distended that the mitral valve was incapable of completely closing it during the ventricular systole, and thus regurgitation was allowed.

Another defect in the action of the heart, consequent upon the morbid state of the valves, was disclosed after death, which had not been previously diagnosticated, the conditions for producing the sign upon which such diagnosis could be founded, being absent. We allude to aortic regurgitation. In its healthy condition the aortic valve completely closes the orifice which it guards during the diastole of the

ventricle, so as to prevent any regurgitation into the ventricle of the blood which has just been forced into the aorta. But in the case before us, the semilunar valves, being converted into a flat membrane, stretched transversely across the commencement of the aorta, and having a small perforation in the centre, could not, it is evident, be so closed as to prevent regurgitation. The diagnostic sign of aortic regurgitation is a murmur accompanying, or supplanting the proper second sound; this was quite absent in this case, and the diagnosis was therefore not obtained. The evident explanation why this morbid sign did not co-exist with a regurgitant state of the valve, is, that the obstruction to the passage of blood into the aorta prevented this vessel ever becoming so distended as, (by the elasticity of its coats,) to force the blood back into the ventricle, with sufficient rapidity to cause sonorous vibrations in the current at the contracted aperture. Connected with this absence of aortic regurgitant murmur, I may likewise notice two other points depending upon the same cause: these are the entire absence of the second sound of the heart, which was noticed upon every examination during life; and the non-occurrence of that peculiar jerking pulse, which is usually so diagnostic of aortic regurgitation. It is the rapid closure of the aortic valves under the pressure of the column of blood contained in the aorta, which causes the natural second sound, but a valve so altered in form as we have seen this to be, was insusceptible of that flapping motion by which the sound is ordinarily produced. The jerking pulse which usually accompanies aortic regurgitation is owing to the arteries, which become distended by the influx of blood caused by each ventricular contraction, again suddenly losing their tension as the blood runs back into the heart; but here the blood could not enter the aorta with sufficient rapidity to produce the necessary distension of the vessels. The pulse was small and soft, not jerking.

Besides the heart, other organs were also the seat of disease which was diagnosticated during life, and which was apparent in the *post-mortem* examination. These organs were the liver and kidneys; and the disease in both was of an hyperæmic or congestive character, and doubtless dependent upon that of the heart. It is a general effect of diseases of the heart, impeding the transmission of blood through this organ, to produce congestion of other viscera which lie behind it in the course of the circulation. As the chief disease here was in the left side of the heart, and the lungs are the organ which lie immediately behind this, we might have expected to find in them much congestion of blood or serous effusion. This is common in analogous cases,—the blood, unable to pass freely through the left ventricle, is thrown back upon the lungs, and there distends its vessels, and part escapes as serum, causing serous infiltration. We had noticed (as is stated in the report of the case,) the absence of sub-crepitant, or mucocrepitant, rhonchus, which is the physical sign accompanying this condition of lungs; and the *post-mortem* examination showed that this condition was absent till the close of life. Can the pressure upon the lungs, of a heart so much enlarged, have given to the vessels of the former organs such resistance as to prevent their yielding to the force of the blood, and becoming overdistended? Some months before death, we had diagnosticated the absence of serous effusion into the pleura. After death we found a large effusion in these cavities. No examination upon this point had been made for a considerable time before death; and such effusions into the serous sacs very commonly occur at the close of life, indeed, in *articulo mortis*, especially where there is much tendency to venous congestion.

Tracing the course of the circulation backwards, the next important organs we come to are the liver on the ascending, and the brain on the descending, vena cava. The brain was not examined. With the exception of that attack with which my attendance commenced, there were no particular indications of disorder of this organ. The brain seems to suffer more in those diseases of the heart where the chief effect upon the circulation is communicated *forwards*,—that is, along the arteries, not backwards along the veins;—by hypertrophy, for instance, but without valvular obstruction. In such a case the blood is impelled along the arteries with undue force into the brain, and serious symptoms, either of cerebral excitement or congestion, may be produced.

There were, however, sufficient proofs during life of serious disease in the liver, which organ more, and sooner than any other, suffers from the congestion of the venous system, consequent upon valvular disease of the heart. The venous circulation through the liver, and the direct communication of the hepatic veins with the ascending vena cava, particularly favour this congestion. The chief symptoms of hepatic congestion were the dropsy, which, in the form of ascites, most commonly depends upon this cause; the pink sediment in the urine; the purple and congested appearance of the tongue, which condition of this organ, from its anatomical connection with the abdominal viscera, more particularly indicates congestion of these parts; the tenderness over the liver, and the increased extent of the hepatic dulness of stroke-sound. When this extends below the margin of the ribs, it betokens either enlargement of the organ, such as is the consequence of congestion, or its displacement downwards, owing to some undue pressure exerted on it by the contents of the thoracic cavity. Both these causes conspired in this case.

The pathological conditions of the liver seem to have been extreme congestion, which had passed into inflammation. The *congestion* was shown by the large size of the liver, and its dark colour. On carefully examining the surface of a section, this was observed to be mottled, a darker ground being variegated with isolated spots of a lighter colour, corresponding with what Kiernan has described as the second stage of hepatic venous congestion. The first effect of congestion of the liver caused by obstruction to the free exit of blood from this organ, as by disease of the heart, is felt in those capillaries which, in the course of the circulation, are nearest to the seat of obstruction,—that is, in the capillaries in which the hepatic veins commence. These have their seat in the centre of each lobule, causing an appearance, when the congestion is

limited to them, of isolated dark spots, upon a paler ground. But, the obstruction continuing, the congestion extends farther backwards. The circumference of the lobules, where the capillaries of the hepatic, coalesce with those of the portal veins, likewise becomes congested, and thus the dark red-colour extends continuously from lobule to lobule, leaving interspaces here and there still uninjected. Such was the condition of the liver in this case. This high degree of congestion predisposes to inflammation; and the results of one of the forms of inflammation to which the liver is subject were apparent in the irregular lobulated surface. The inflammation producing this appearance is seated in the interstitial cellular tissue, in which, as a consequence, coagulated lymph is deposited, at first enlarging the bulk of the liver, but subsequently, by its strong tendency to contraction, diminishing its bulk, and giving to its substance greater density and induration. This subsequent effect of adhesive hepatitis had only been partially produced. The size of the organ was still excessive, depending both on its great congestion, and on the inflammatory deposit; but some contraction of the lymph in the cellular tissue, surrounding groups of lobules, had taken place, causing the depressions between the irregular projections seen on the surface.

A more advanced stage of this form of hepatitis, and where not complicated with so great congestion, constitutes the disease called cirrhosis, or the hob-nail liver, the former name being derived from the yellow colour of the liver, owing to the deposit of lymph in its substance, and the expression of the blood by the contraction of this lymph; the latter, from the irregularities on the surface resembling the heads of nails. At the same time the liver becomes very small, and acquires a dense hard texture. I think, very probably, the amount of contraction which may take place in this disease, depends, not merely upon the length of time that the contractile lymph has been effused, but upon the original property of the lymph. When the inflammation has been of a low character, and the blood poor in quantity, the lymph poured out is *cacoplastic*, incapable of perfect organization, and having a strong tendency (as Dr. C. J. B. Williams has pointed out in his "Principles of Medicine,") to contract and assume a dense, fibro-cartilaginous character. Cirrhosis is chiefly produced in habitual dram-drinkers, whose habits deteriorate the blood, producing the anæmiated shrunken appearance which such persons possess; at the same time that the spirit constantly introduced into the circulation of the liver excites adhesive inflammation, the results of which are *cacoplastic*,—contractile lymph, poured out from ill-conditioned blood. But where the same form of inflammation results from other causes, as in the case under consideration, and with blood of a better quality, there is less tendency to contract; and (especially when complicated with great hepatic congestion,) the liver may remain still large, although sufficient contraction has taken place to produce the usual irregularity of the surface. M. Becquerel considers heart-disease the most common cause of cirrhosis. We agree with Dr. Budd in considering the hepatic congestion commonly produced by heart-disease a strong predisposition, but that some other exciting cause is likewise required; of these, though there may be many others, none is so common as spirit-drinking.

The kidneys were likewise the seat of disease, having a very similar pathological character to that of the liver, arising from the same cause. Their large size, and deep colour, were the marks of congestion, and their dense and firm substance probably depended upon the same cause as did the same properties in the liver,—viz., the interstitial deposition of adhesive lymph. We think the kidneys were, in an early stage of that disease, which in a more advanced form is known as the granular kidney; and we consider this disease to be very similar in its nature to cirrhosis in the liver,—that is, to depend on the deposition of a cacoplastic contractile lymph in the interstitial cellular tissue, causing, in both cases, when fully developed, a diminution in the size of the organ, and great increase of hardness and density, and producing an irregularity of the surface in both cases. These irregularities are of a granular form on the kidney, more polyhedral on the liver, the difference depending upon the different distribution of the interstitial cellular tissue, and the secreting structure in the two glands. In both cases, likewise,—viz., in cirrhosis and in granular kidney, we have the same pale yellowish-colour of the diseased organ, depending upon the prevalence of the morbid lymph, and the obliteration of the natural tissue.

In the kidneys, however, in this case, as we have seen in the liver, not much contraction had occurred up to the time of death. No irregularity of the surface was produced; but the nature of the disease was illustrated by the symptom of albuminous urine during life, the more pathognomonic symptom of the morbus Brightii, which terminates in granular kidney.

There were one or two particulars with reference to the characters of the urine, worthy of some notice. The pink sediment was of as full and decided a pink colour as is often seen. This kind of sediment is usually regarded as a symptom of visceral disease, and especially of disease of the liver. Prout says he has never seen a pink sediment co-exist with albuminous urine; this combination, however, existed in this case, and there seems no, *a priori*, improbability of the co-existence of these symptoms.

It is true that in that form of liver disease,—viz., cirrhosis, which, more than others, accompanies the granular degeneration of the kidney, (of which latter, albuminous urine is usually a symptom,) we do not commonly meet with a decidedly pink sediment in the urine; for the pink sediment usually accompanies the congestive or hyperæmic diseases of the liver, with much functional derangement of its proper secreting functions. Whereas, in simple cirrhosis, the inflammation being seated in the cellular tissue, rather than in the secreting structure of the liver, the function is not much interfered with, until the contracting lymph causes a mechanical pressure upon all the textures, and blood-vessels and biliary ducts become gradually obliterated. But there is no reason why other congestive or inflammatory affections of the liver should not co-exist with granular disease of the kidney; and

farther, we may have serous urine independently of granular disease of the kidney.

The form of the crystals of lithic gravel in the urine, observed under the microscope, was unusual, and what I have seen in no other case but this. A common form is that of lozenge-shaped lamellæ. In this, the outline was very much like that of a barrel. I think this unusual form was produced by the truncation of the four angles of the lozenge, and their being replaced by planes. They answered to the chemical tests of lithic acid.

I have before said that I consider the immediate cause of death to have been syncope. The heart, overworked by having constantly to propel the blood through a contracted aortic aperture, and part of the force of each ventricular contraction being lost by regurgitation, and its contractile power being still further enfeebled by congestion of its own tissue, at length ceased to act, arterial blood no longer circulated through the brain, and death was the result.

Probably the pressure of the stomach, distended by the food which had just been eaten, upon this embarrassed heart, increased the obstruction to that degree which could not for a moment be overcome, and death occurred before the heart had time again to collect its powers to continue the contest. Had diffusible stimulants been promptly administered, before life was extinct, this might have enabled the heart to rally, and pursue its weary task for somewhat longer.

I shall say very few words upon the *treatment* of this case. From the time when it first came under my notice, it was evidently one for palliatives only, and was not susceptible of cure. The organic injury to the valves of the heart could not be repaired; we could only endeavour to relieve or obviate the consequences of such a lesion. Before I first saw the patient, the great congestion which accompanied the attack which led to my attendance, had been properly relieved by moderate local depletion. The probability of cerebral congestion, likewise, might have suggested a more active depletion by the lancet; but in such disease of the heart, the tendency to fatal syncope should enforce the greatest caution and discretion in the removal of blood. The moderate depletion which had been practised, together with a brisk purgative, had relieved the more urgent symptoms; and the chief indications were then to remove the great amount of visceral congestion, and that of the heart, by promoting the secretions, and by counter-irritants deriving to the surface. These indications were fulfilled by the application of a blister, and by saline purgatives and diuretics, acting freely on the intestinal mucous membrane, and liver, and on the kidneys; and the action on each of these secreting organs was likewise promoted by the valuable combination of blue-pill, with squills and digitalis, so much in use. The mercurial was continued till the gums were slightly affected; after which the iodide of potassium, a milder remedy, but possessing a similar action, was substituted. Under this treatment all the secretions became more free, and as a consequence, the general congestion of the venous system was much relieved. A mild tonic treatment was then adopted to improve the tone of the system, and enable it better to contend with the incurable organic lesion; but still combined with mildly diuretic and cholagogue remedies, to keep the secretions free, and counteract any constringing action on the part of the tonic medicines. At the same time, exercise only of the quietest kind, and the avoidance of all excitement were strictly enjoined; and a nutritious diet, but unstimulating, and not too much diluted with watery liquids, which are rapidly conveyed into the veins, increasing the distension of these vessels, and adding to the labour of the heart, but supplying no materials for textural nutrition. Under this plan of treatment he enjoyed, for a considerable interval, a more comfortable degree of health than had fallen to his lot for long previously; but the over-wrought heart was constantly strained to its utmost power; and like the last straw which broke the camel's back, the slight obstruction occasioned by a distended stomach, seems to have been the trivial cause of the final arrest of its motion.

CASE OF FUNGUS HÆMATODES IN THE BRAIN.

By John Prankerd, Esq., Surgeon, Langport.

The records of surgery furnish numerous instances, in which patients have lived a considerable time with balls and other foreign bodies lodged in the cavity of the cranium; but I believe there are few recorded where the substance of one hemisphere of the brain has been nearly destroyed, and yet the patient lived many years with the intellectual faculties unimpaired. The following case I venture to bring before the Association, as affording some points of interest, particularly with reference to certain views that have been recently promulgated by the late Dr. Wigan, and which it would appear to corroborate:—

Mary Gillard, aged 44, married, menstruated regularly, and mother of several children, for the last ten years of her life suffered from intense pain in the head, occurring at intervals, and for nearly the whole of this time (nine out of the ten years,) was completely blind. For the last few years, her health was evidently affected by the continued suffering she endured. Latterly, counter-irritation, such as setons, issues, and the long issue through the scalp, were principally relied on, but afforded only temporary relief, and she was gradually worn down by the suffering, and ultimately sank, exhausted. Throughout the whole period her mental powers were unimpaired; she was very conversible and intelligent, and her symptoms were not such as would indicate that much structural disease of the brain existed.

Autopsy, eight hours after death.—The head only was examined. The right hemisphere of the brain was healthy; the *left* rather softened, and the anterior and inferior portion was occupied by a firm tumour, weighing upwards of eight ounces, of an oval shape, and occupying more space than a cricket ball. In appearance it was of a dark purple colour, and in structure lobulated. The optic nerve was found

extremely small, having suffered gradual compression during the increase of the tumour.

The tumour I sent to a pupil studying at King's College, and it was examined by Mr. Bowman of that Institution, who pronounced it to be a decidedly fungoid growth. In some portions the blood-vessels had given way, constituting fungus hæmatodes, and other parts presented the character of medullary sarcoma. A section examined under the microscope presented a number of healthy nucleated cells, interspersed with some that were diseased; the latter were larger than the former, and contained within them smaller cells. In the substance of the tumour numerous fibrous bands might be discerned with the naked eye. The tumour was highly organized, and very vascular. Mr. Bowman thought the case extremely interesting from the unusual size of the tumour, the slowness of its growth, (ten years,) and the absence of any disturbance in the functions of the brain. This last circumstance is perhaps the chief peculiarity connected with this case, and when we think that for a considerable time, nearly the whole of the left hemisphere of the brain was obliterated, and occupied by a malignant tumour, without interfering with the operations of the mind, the fact seems explicable only on the views of Foville and Wigan,—that the two hemispheres constitute two distinct brains, (connected, it is true,) but each, individually, capable of carrying on the various mental operations independently of the other, just as we see in the eyes, ears, &c.

In addition to the analogies presented by the special senses in support of the theory of the duality of the mind, numerous facts, hitherto inexplicable in health, but more especially in disease, point to this source for an explanation. The phenomena of insanity, which have occupied the thoughts of the profoundest minds, and are still involved in mystery, afford many instances corroborative of Dr. Wigan's views. He considers each brain as a perfect whole, in thought, sentiment, and volition; and also, that when one of them is destroyed, the other can perform all the functions of the mind. Each brain carries on its own processes independently, and, like the two strings of a piano-forte, producing only one note. In both cases, it is only when they are out of harmony that the fact is observed, that that which is apparently *one* is really an harmonious combination of two distinct actions. A discrepancy in the action of the two brains,—a mixture of two trains of thought produces confusion, incoherence, and ultimately, when both brains become disordered, insanity. That two processes of thought seem constantly to be going on in the insane has been observed by many persons conversant with them. The ready explanation of the phenomena of dreams also seems naturally to suggest itself as illustrative of these views—that one brain may be in repose whilst the other is in a state of greater or less activity. With respect to the assertion that one brain is capable of carrying on all the mental operations, I may adduce an instance from a pamphlet of Dr. Wigan's, which he mentions as coming under his own observation:—

"When the disordered feelings, thoughts, reasoning powers, sentiments, and volitions of one brain have, by their incessant obtrusion, overpowered the same impulses, reasoning powers, and volitions of the other, and thus produced insanity,—if the further progress of disease in the organ pass on to its utter destruction, the patient is immediately restored to reason; apoplexy in the disordered brain, for example, producing hemiplegia, by liberating the healthy organ from the suggestions of the other, will in a few moments enable the patient to use the sound brain as fully as if it had never been in abeyance."

The same writer also brings forward a very amusing poetical letter, written by the late Stewart Rose, long after he had entirely lost one brain.

I might adduce many facts which would support this theory, but I should prefer referring you to Dr. Wigan's work; and I have no intention, neither am I prepared to enter into the discussion of this interesting question; indeed, it is far too complicated and extended, and I have only made this case the occasion of a few remarks on the subject in the hope that it may direct attention to this important branch of inquiry. I do not profess to be a convert to the theory that Dr. Wigan has advocated in his work on "The Duality of the Mind"; but as it affords a not unphilosophical explanation of many parts hitherto inexplicable, I think it demands from us at the least a calm and unbiassed investigation.

CASE OF GENERAL ANASARCA, WITH ALBUMINOUS URINE, IN AN INFANT TEN WEEKS OLD.

By W. Bird Herapath, M.B., Surgeon to St. Peter's Hospital, Bristol.

March 17, 1848. Mrs. Penfold brought her infant to me, complaining that it had "swollen very much all over." This state came on gradually about a fortnight ago, and she could assign no cause for its appearance. It was a male infant about ten weeks old; the whole surface had a peculiar anæmic aspect; the eyelids were transparent and swollen from œdema; the face was also somewhat anasarcous. The inferior extremities and the hands showed this condition the most; they were at least double the usual size, and pitted deeply upon pressure. The child's health did not appear to be otherwise disordered; it ate its food well, and took the breast also; it was by no means a restless child, for she had generally "very good nights" with it. The mucous membranes all appeared in good order; there was no bronchitis nor other symptoms of catarrh. It generally made plenty of water, and appeared to thrive very well until this came on. At a subsequent period I obtained a small quantity of the urine, it was clear, but high coloured, and deposited abundance of albumen, with nitric acid, and heat.

These symptoms gradually became worse, in spite of all treatment; occasionally all the swelling disappeared, but it soon returned. I saw the child frequently, but never found the albumen to decrease in the urine. Its food appeared to do it no good; the nutritive function was decidedly interfered with.

About the latter end of April the infant became drowsy and comatose, and the anasarca was at this time worse than ever; convulsions ensued, and rapidly carried it off. The infant died twenty-four hours after

their first appearance; it was then four months and a fortnight old.

Post-mortem examination, May 1st, 1848. A most careful examination was instituted. The whole thoracic and abdominal organs were perfectly healthy in structure; the kidneys had not the slightest approach to granular disease, and no structural cause was elicited for the death of the little patient. All the organs were remarkably anæmic and pale; I never saw an instance in which there was so great a deficiency of colouring matter. Had the patient been slowly bled to death, it could not have been more bloodless and pallid; the liver alone had any appearance of blood in its tissues. It was in a slight degree congested in the hepatic venous system.

Remarks.—The treatment consisted at first of diaphoretics. Antimony and nitric æther, combined with small doses of tincture of digitalis, were first administered, and a warm bath every other night during five minutes. Some little benefit was derived from this mode of treatment, but eventually it was of no service. The nitro-hydrochloric acid was then tried, and the mother fancied more benefit was obtained from it than from the other attempts. This was continued for about three weeks, but after this I saw no more of the child until called upon to give a certificate of its death, when I of course demanded an examination of the body. Anæmia appears to have been the cause of the general anasarca, but the mal-assimilation of its nutriment was probably the primary cause of the albuminuria and anæmia consequent upon it.

OBSERVATIONS ON HERNIA.

By John Allan, Esq., Surgeon, Epsom.

The usual progress of hernia is from bad to worse; it seems, therefore, worth while to record two cases, in one of which gradual reduction took place, long after all attempts at reduction had been abandoned as impracticable; while in the other, not only reduction, but a permanent radical cure, has been obtained.

William West, aged 64, had had hernia of the right groin for upwards of twenty years, for which he had worn a truss very constantly, though not without occasional omissions, when, from the heat of summer or other causes, he felt it inconvenient. About six months ago I was requested to see him, when I found him engaged in his usual duties as an under-gardener. At this time the hernia was as large as a goose's egg, extending half way down the scrotum, tense and hard, but not painful, nor tender. He had not been able for three weeks to effect its reduction, which he had been in the habit of doing without difficulty. He had broken the spring of his truss, but, binding it tighter, he had continued wearing it for several weeks, till the broken end of the spring having at length worn a hole through the leathern sheath, had begun to gall his back. A person to whom he mentioned the circumstances, gave him a second-hand truss, which, though much too wide to fit him, he had worn for a week, although the hernia protruded every day while the truss was on. At length he found that he could not reduce the hernia at all, and went to the Society's house in Hatton Garden, where he got a new truss of a size to fit him. The surgeon then attempted without success to reduce the hernia, and advised him to remain at rest, and to purge his bowels well, and that then he might succeed in reducing the hernia. When I first saw him it had been un-reduced for three weeks, and was increasing in size.

I ordered him to be confined in the supine posture in bed, and to apply constantly cold astringent lotions to the tumour, while he took opium in one grain doses every hour, till he was narcotized by it. Day after day the taxis was carefully tried, after the fullest expirations, but only with very partial success. The hernia appeared to consist chiefly of omentum, but the gurgling sound of air under the hand showed that the intestine was also concerned. His bowels were not obstructed, and were freely purged with castor oil and croton oil, and the use of opium was renewed at intervals for six days. The tumour was now reduced to the size of a hen's egg, and was soft and free from tension or tenderness, but would not admit of being replaced within the abdomen, after repeated and long continued manipulation.

Under these circumstances, it seemed reasonable to conclude that adhesion of part of the contents to the sac must have taken place, and that any further reduction of the hernia was not to be expected. A truss, with a cupped pad to receive and fit the tumour, was now made for him, and, with this fitted on, he left his bed and resumed his usual occupation. After a day or two the cup of the pad seeming larger than necessary, two or three folds of linen were placed between it and the tumour. From time to time the quantity of linen was increased, and every night, while in bed, he made careful attempts to reduce the hernia, which, at the end of a fortnight, he effectually accomplished. Ever since then he has worn the ordinary truss, which he received from the Truss Society, and has not again allowed the hernia to protrude in the slightest degree.

It is probable that, in this case, partial absorption of the bulk of protruded omentum had taken place under the pressure of the truss, till at length it became so far lessened as to slip through the ring. I confess that this result was to me quite a surprise, for I had no doubt that adhesions must have been formed between the sac and its contents, which would render the total reduction of the hernia impracticable.

The other case which I have to describe, I consider still more remarkable, and I am not aware that there is any case parallel to it on record.

William Puttock, 34 years of age, had had a rupture of the right groin while a boy, which he used to reduce at pleasure. At the age of fourteen it would sometimes come down to the size of two fists. About this time he was in the service of a coal-dealer, and found that the frequent lifting of sacks of coals caused the rupture to increase in size. One day, on moving a number of sacks, the tumour suddenly enlarged to the size of his head, and became hot and painful, and of a deep-red

colour. His master, seeing how ill he was, ordered him to bed, and sent for a surgeon, who, as soon as he saw the tumour, gave the most unfavourable prognosis. He gave no hope of life being saved. He applied refrigerant lotions, and a bandage to the tumour, and ordered the patient to be provided with brandy and water. Contrary to all anticipations, the inflammation abated, and the tumour gradually decreased in size, till at length it became reducible within the abdomen. Then, for the first time, this patient was provided with a truss. The surgeon who fitted it on, told him he might find the pressure of it painful at first, but that he must submit to it, as his life might be the forfeit if he left off wearing it. Notwithstanding great pain and excoriation, he wore the truss for five or six years, when the spring having for some time been very rusty, broke in two; then, instead of procuring a new truss, his wife made a firm pad of flannel, covered with leather, which he secured in the groin by bands around the pelvis, and between the thighs. This he wore daily for two years, when, in hot weather, finding it galling and uncomfortable, he took it off one evening as soon as he got home from his work. Next evening he did the same, and, as the rupture did not come down in the least either night, he went to work the third day without the pad. To his great delight he has never had any further occasion to wear it, as the rupture has entirely ceased to descend at any time.

There is now not the least vestige of hernia in his groin, and, without knowing anything of the preceding history, I had occasion, several years ago, to examine him as to his fitness to be admitted into a benefit society, when I gave a certificate of his being free from hernia, &c. At the present time he has the situation of a groom, with frequent occasion to be on horseback, and has not the least apparent vestige of hernia about him.

In this case it is probable that the inflammation occasioned by wearing the truss at first had extended to the subcutaneous tissues, and obliterated the inguinal ring through which the hernia had protruded, the hernial sac becoming gradually absorbed. It is worthy of remark that, notwithstanding the alarm the local appearances were calculated to inspire, neither of these two patients was at any time affected with symptoms of strangulation.

SHORT NOTES ON THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Treatment of the First Species of Gonorrhœa.—(*Continued.*)—The disease may sometimes, however, be considerably shortened by medicines which tend to impede the discharge, and these remedies may be either given internally, or used externally; the former consist of terebinthinate medicines, such as the balsam of copaiba, &c., but they are not admissible when the neck of the bladder and perineum are affected. These medicines may frequently check the discharge even at an early period of the disease; it must be admitted, at the same time, that they often do no good, but rather exasperate the symptoms, rendering the discharge liable to return when the medicine is discontinued, and sometimes producing dysuria and strangury.

External remedies are applied in the form of injections, which are of various kinds,—viz., oily, mucilaginous, mercurial, and astringent; and these are occasionally combined with opium.

Oil may be considered as injurious to the urethra, as it rather aggravates than alleviates pain; mucilaginous injections do nothing more than defend the urethra from the salts contained in the urine, and must be washed off the first time the urine is passed; and injections in which mercury is suspended, act, probably, as astringent and defensive. Those holding the bichloride of mercury in solution, must be both astringent and irritating. The late Mr. Bromfield used this in the proportion of one grain of the sublimate, to half a pint of water. Astringent injections, either of solutions of the di-acetate of lead, of the sulphate of zinc, or the sulphate of copper, by suppressing the discharge early, sometimes obtain a speedy termination of the disease. It is not obvious how the complaint is removed by suppressing the secretion, but the fact is sufficiently certain.

If a patient with mild gonorrhœa apply for advice on the first or second day from the commencement of the disease, and if an injection be prescribed, composed of from eight to twelve grains of the sulphate of zinc to eight ounces of water, which is to be used three or four times a day after passing the urine, the discharge will probably be got rid of in from one to three weeks, and in some instances be completely removed in a week.

An injection should not be violently thrown into the canal, nor be suffered to remain there longer than half a minute. If the di-acetate of lead be employed, half a drachm may be dissolved in half a pint of water, or it may be added to the zinc injection above-mentioned, as it will tend to diminish the stimulating properties of the latter. The sulphate of alum is not admissible, except in the last stage of gonorrhœa. Injections containing a fit proportion of laudanum do not appear to effect any material benefit by the addition of this drug.

During the use of an injection, if the symptoms increase, it should be immediately discontinued; and it ought never to be thrown farther into the canal than the projecting part of the penis. This limit may be effected by pressure of the corpus spongiosum at this point.

Injections upon the whole are not to be approved; and but for the necessity of using them in certain

* Continued from page 347.

individuals, it were better to lay them aside; for it cannot be denied that they frequently produce troublesome symptoms, and sometimes give rise to urethral stricture; besides, it is very common for the discharge to return, if the injection has been discontinued before a fortnight from the appearance of the complaint.

Injections are often deemed more serviceable than they really are to the patient; for even when the discharge has ceased, it is necessary to continue them so long, in many instances, that it is probable the antiphlogistic plan might have succeeded equally well without them.

If the patient should be seized with pain in the loins, or strangury, under the use of injections, they should be instantly left off, and the warm bath substituted; for in such a case the object will be to bring back the discharge as quickly as possible.

Injections are not attended with the same risk in females, the urethra being seldom affected, and the vagina not possessing so much sensibility as the male urethra. An injection composed of three drachms of the sulphate of zinc, one drachm of the sulphate of alum, one drachm of the superacetate of lead, and one quart of water, may be used in such cases; and to sheath the parts from the acrimonous quality of the discharge, the inner surface of the labii may be smeared with an ointment composed of one part of the Unguentum Hydrargyri Fortius, and five parts of fresh Unguentum Sambuciflorum.

Treatment of the Second Species of Gonorrhœa.—As the inflammation in this species extends as far as the bulb of the urethra, or neck of the bladder, so the symptoms are more severe, and are attended with more important consequences.

Injections of every kind in this case are injurious, and the most effective means of relief are those which remove inflammation.

Purgatives, such as calomel, with jalap, or the sulphate of magnesia, are to be given every two or three days, or as often as the patient can bear them. If there be much spasm or inflammation of the perineum, leeches are to be applied every day till the inflammation is mitigated or subdued. The vapour of hot water, fomentations of poppy decoction, or a bladder of hot water, may be applied to the perineum, and afterwards a warm poultice of linseed meal. If the ardor urinæ be excessive, it may be alleviated by immersing the penis in hot water, when the urine is being passed.

At the same time relief will be obtained by the internal administration of small doses of nitre, with large doses of the compound tragacanth powder; along with this the patient should drink largely of a decoction of marsh-mallows, barley water, or linseed tea, and by these means he will abate the heat that is felt through the whole course of the urethra, and particularly at its bulb.

In these severe cases it will also be right to give one or two grains of calomel, with half a grain of opium every night; not so much to prevent lues, as to remove the urethral inflammation; and when the inflammation is very acute, ipecacuanha or antimony may be added.

When the inflammation has been subdued, and the discharge has become white and thick, a stop may be put to it, not by injections, but by the balsam of copaiba. It may be given in this form:—R. Balsam. Copaibæ, dr. j.; Misturæ Acaciæ, dr. ij.; Tincturæ Opii, gtt. x; Aquæ Rosæ, dr. x. Misce pro haustu bis terve die sumend. But if no good be experienced the first week, it must not be exhibited afterwards. If the discharge has ceased, it will be proper to continue the balsam eight or ten days, lest it should return.

The balsam disagrees with the constitution, producing, in some persons, sickness and vomiting, and in others an exanthematous eruption and disorder of the general health; in such results it must be at once discontinued, and a purgative given. Small doses of the Oleum Terebinthinæ have been substituted, but in general the latter disagrees more than the former.

This form of the disease requires eight or nine weeks to be subdued, and if it be not very correctly treated in the beginning, will often last eight, nine, or ten months; with the greatest possible care it is seldom cured in a shorter time than six or seven weeks. The strictest attention to diet and exercise is indispensable.

Treatment of particular Symptoms: Inflammation of the Perineum.—When the perineum is tender and painful, and this state of the parts is not early removed by local bleeding, by purging, the warm barth, poultices, and opiate enemata, it is probable that suppuration will take place in the cellular tissue. It is generally long in coming forward, and as soon as fluctuation can be felt, it is right to evacuate the matter with a lancet, in order to prevent the urethra from being injured, which is not necessarily involved in this case.

Treatment of Chordee.—This symptom is sometimes carried off suddenly by copious hæmorrhage, and this is occasionally produced by an attempt to lacerate the frænum. Injections of every kind should be laid aside, as well as all restraining medicines. If the pain be severe, and the tensions constant, bleeding, with leeches, or opening the vein of the dorsum penis, will be found beneficial. Immersing the penis in hot water, and sitting in a warm bath for some time, may also be of use. Purgatives are required, and a plaster of camphorated mercurial ointment should be applied along the under part of the penis.

Opium, however, is the chief remedy; it should be given in large doses on going to bed, and repeated upon every painful return of the priapism. It may occasionally be combined with æther and camphor with advantage.

The frænum ought never to be divided except from absolute necessity,—that is, when it is too short; for when divided, relief is not obtained from the division so much as from the hæmorrhage; indeed in some cases, by cutting the nerves running on each side of the frænum, great and permanent injury has been inflicted upon the patient. If its division be deemed indispensable, a perforation should be made behind the frænum for the passing of a ligature to tie it. The ligature will be thrown off in three or four days, and the sore will probably heal without any trouble.

The treatment of phymosis and paraphymosis has been before noticed. When they arise from gonorrhœa, extreme cleanliness will be all that is necessary.

[When phymosis arises in gonorrhœa, or on simple abrasion of the surface of the glans, a solution of one grain of the sulphate of zinc, in one ounce of water, injected between the prepuce and glans, will invariably heal the abraded surface, and speedily reduce the swelling of the prepuce.]

Treatment of Enlargement of the Inguinal Glands.—When these glands are enlarged, either from acute inflammation, or from a suppression of the discharge, they are to be treated by smart purgatives and other antiphlogistic means.

Treatment of Strangury or Irritability of the Bladder.—In this case there is generally a tendency to suppuration as well as to inflammation, it is, therefore, important to reduce the latter as soon as possible. Leeches should be applied to the perineum as near the prostate gland as possible, and the bleeding be promoted by warm poultices. The warm bath should be used, and the patient kept in bed.

When the inflammatory symptoms shall have been subdued, opium given freely, particularly by the rectum, will be found of considerable service; purgative enemata also are useful; and it is a great object to bring on a copious discharge.

Treatment of Inflammation of the Testis.—As this disease is generally regarded as purely inflammatory, twelve or fourteen leeches are to be applied to the scrotum; and if the symptoms be severe, twelve or sixteen ounces of blood may be taken from the arm. The leeches should be repeated every day till the violence of the symptoms is subdued. During the intervals a hot linseed poultice may be applied. Warm applications have been found more useful than cold. At the same time calomel and senna purges should be given, and the patient kept on low diet, and confined to his bed.

When the inflammation has been subdued, much benefit will be received by the use of injections, every night, of the infusion of linseed, with fifty or sixty drops of laudanum; and small doses of calomel are to be given every day. This plan is generally successful in producing a remission of the symptoms in eight or ten days; but the whole of the inflammation will sometimes not subside under five or six weeks; a soap-plaster may be afterwards applied, and the scrotum suspended.

When a patient is threatened with phlegmone testis, sometimes a brisk purgative, and washing the scrotum with warm brandy, will prevent the disease. Emetics will prove of no avail.

If, after the inflammation has subsided, any hardness of the epididymis or thickening of the spermatic cord remain, the camphorated mercurial ointment and spirituous vapour may be used; and if these fail, a blister may be applied to the testis, and another over the abdominal ring.

If the inflammation be of the indolent kind, it will be useful to employ a poultice made of the fresh leaves of hemlock, and to give small doses of the corrosive sublimate, in a decoction of sarsaparilla.

The discharge of the urethra is generally restored as the testicle improves; but the latter often remains in an indolent state for years, and as there is no disposition to its becoming scirrhous it is of little importance. The camphorated mercurial ointment may be used; or, in the event of its failing, electricity may be tried. In some cases mercury has appeared to do good; but it will often be found to disappoint such an expectation.

If the patient has delayed too long before he applies for assistance, the scrotum, and sometimes the testicle itself, will suppurate. In such a case, poultices are to be applied, and should there be a disposition of the parts to slough, they should be continued till the sloughs have separated, and then the surfaces may be washed with Bate's camphorated water, and afterwards covered with dry lint. Greasy applications are not found to agree so well.

Atrophy of the testis does not frequently occur; but if it should be the result of phlegmone testis, blisters and electricity may be beneficial, although these remedies cannot always be relied on.

Treatment of Dysuria Venerea Sicca.—When this kind of dysuria occurs primarily, purgatives are to be chiefly depended upon for its cure; and with this view calomel may be given at night, and jalap in the morning; and this plan is to be repeated every third day. Small doses of calomel should also be given three times a day, and strong mercurial ointment rubbed in along the course of the urethra. If there be much pain, the tepid bath will be found of use.

When dysuria sicca supervenes in gonorrhœa, blistering the perineum should be employed. An ointment of cantharides may be applied to the glans penis, so as to produce excoriation of its surface and also of the inner part of the prepuce. This application, by producing a discharge, will be found beneficial. Bark and the extract of hemlock may be given internally, but the effect of these medicines is uncertain.

The Treatment of Gonorrhœa in Females is similar to that recommended for males, except that in the former, astringent injections may be used of much greater strength, and at an earlier period, but not till the primary symptoms shall have subsided.

Whilst these are present, a solution of the Plumbi Diacetas may be used, and afterwards the following:—Zinci Sulphatis, dr. iv.; Aluminis Sulphatis, dr. ij.; Pulv. Plumbi Compositi, oz. j., Aquæ simplicis, Oij.

[The compound lead powder will be found in the L. P. 1788. Take of Ceruse five ounces, Sarcocol one ounce and a half, Tragacanth half an ounce. Rub them together into powder.]

In some cases ten grains of the bichloride of mercury may be dissolved in a quart of water for the same purpose.

The discharge is often extremely obstinate, in which case the balsam of copaiba, turpentine, olibanum, the sulphate of zinc, and bark may be given; and if the disease should not yield to these, the patient may take five or six grains of the sulphate of alum, with ten grains of the Sanguis Draconis three times a-day; the cold bath, also, may be added, if necessary, which is often found efficacious in females.

Treatment of Tumour of the Labium Pudendi.—This requires little more than the usual treatment of inflammation. The parts should be fomented and poulticed.

If an abscess of the lacunæ break spontaneously, it is apt to continue for a long time, and is often mistaken for gleet or internal abscess. The true character of the case may be known by considerable fulness and hardness of the labium on the side involved.

The best treatment will be to lay open the abscess by a crucial incision, to dress it down with dry lint, and afterwards to cover it with an emollient poultice. In a few days the sore might be sprinkled with red precipitate powder, so as to produce a slough of the lower surface of the sac; and when the sac has been thus obliterated, healthy granulations will probably form, and the cavity soon be filled up and healed.

Southampton, June 1st, 1848.

CASES FROM PRIVATE PRACTICE.*

By John Richard Wardell, M.D., Edin.

Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

Case VIII.

SUBCLAVIAN ANEURISM.

Remarks.

Aneurismal tumours, both on the part of surgeons and physicians, have in later times received the special attention of accurate observers, so that now their pathology is well understood, and more correct notion entertained respecting their causes; nor is it surprising that so many inquirers have interested themselves in the subject, seeing that the affection is one of the gravest character, and when occurring in certain of the larger vessels, admits not of cure. Galen was the first who entertained any just notions of the disease; afterwards Vesalius and some others made attempts at giving a description of it. In more recent times Lancisi, Guattani, Monro, Morgagni, Scarpa, Hunter, Hodgson, Breschet, &c., have given elaborate accounts of every kind of aneurism. Various experiments have been tried upon animals, both in ascertaining their cause, and the best means of medical as well as operative cure. The former has manifestly little, if any, effect, notwithstanding the assertions of Valsalva and his followers; and where the surgeon's art is impracticable, we may deem the case as one of a hopeless nature. It is true that in certain rare instances a spontaneous cure has taken place, even in aneurismal enlargements of the great vessels, yet such are rare instances, and in our prognosis could form nothing more than a remote possibility.

Aneurisms may be divided into two great classes, *spontaneous* and *accidental*, the former resulting from a gradual and diseased change in the coats of the vessel, almost invariably the middle and internal tunics first becoming affected; the latter from sudden and positive laceration of the coats, as by powerful exercise, sudden tension, and external injuries.

Some authorities have affirmed, relative to spontaneous aneurism, that there is *invariably*, a giving-way of the middle coat; and such was the opinion of Scarpa, who says, "there is only one form of the disease,—viz., that caused by a rupture of the proper coats of the artery, and an effusion of arterial blood into the cellular sheath which surrounds the ruptured artery," a doctrine which, although is in the main correct, is not at all times true, because we know that dissection has in some instances proved the contrary. The whole of the coats may, by long-continued disease, become so softened and deprived of their natural elasticity, as to simultaneously dilate, and this dilatation has been known to progress to a very considerable degree, all the tunics preserving their integrity. The fibrous or middle tunic is by far most apt to assume a morbid state; it loses its natural consistency, and becomes soft and flabby; in the interstices are often deposited calcareous matters, when the lining membrane changes to an indurated condition, and thus is rendered very liable to rupture. Sometimes dilatation will go on for a considerable period, and then the internal coats divide, as if from rupture, induced by over dilatation. The atheromatous condition of the fibrous tunic is the morbid state most commonly observed, and to this opinion the majority of morbid anatomists have subscribed. In those vessels which are subject

* Continued from page 379.

to much action, as the popliteal, disease is more prone to become manifest; hence the well-known fact of lamp-lighters and postilions being so liable to have bloody tumours in that part; and I well remember, when studying in Edinburgh, the observation was repeatedly made, that aneurism of the arch of the aorta was much more prevalent in the large towns of Scotland than England, dependent on the inhabitants living in flats, and thus the excitement given to the circulation, by ascending a considerable number of steps, by degrees induced dilatation of the arch. The long straight portions of an arterial trunk are never so liable to manifest morbid changes as the curvatures and the junctions of branches, the reason of which, on reflection, is obvious. When the blood, *in transitu*, impinges with more force against one part of the walls of the vessel, at such points will disease be liable to occur, because the vasa vasorum may thus be impaired in their functions or structure; hence the healthy vitality of the tissues which they nourish will be in some degree diminished, thus predisposing to morbid action, and because by long and continuous repetition, slight disorganization, by softening or rupturing the elementary fibres might be caused. The great power with which the column of blood is sent from the left ventricle into the arch, no doubt contributes to the predisponent causes in the induction of frequent aneurismal enlargement, and especially where there is valvular or other obstruction, and an anormal divergence is given to the current. Morbidly increased impulse, especially if concentrated at certain points, cannot fail to endanger the healthy condition of the tissues at those points. Philosophical experiments made long ago by Lancisi and others, on leaden water-pipes, proved that partial obstructions made in the course of the pipe, and thus impelling the fluid with force towards a certain point, will burst the walls of the pipe; hence, deducing an analogy from such experiments, we may see the manner in which irregularities in the arterial trunks are calculated to operate, because the two fluids, in their transit, are subject to the same natural laws.

In spontaneous aneurism it does not always happen that there is entire dilatation,—that is of the calibre of the vessel, and thus a nodus, bulges from one side, the opposite lateral aspect of the arterial trunk preserving its natural evenness. When, however, the disease has for some time progressed, the entire walls of the vessel become diseased, that portion of the trunk dilating the most, against which least resistance is offered by the juxta-position of other organs; hence in aneurisms which have been called visible or external, as in this instance, we see the pointing was towards the surface. In spontaneous aneurism, the patient cannot with any preciseness mention the period of its commencement, whilst on the other hand those, for sake of contra-distinction, termed *accidental*, can generally be referred to a particular time, when of course the laceration of the fibrous coat would produce some degree of pain, or a sensation of giving way. Armstrong, as mentioned in the report, could assign no cause for the tumour, nor with any degree of exactness speak of its origin; hence it is fair to presume that it was rather referable to gradual disease of the tunics than to their rupture.

I have above observed that Scarpa contended for rupture of the fibrous tunic, indeed he denied the existence of aneurism without the middle tunic giving way. Mr. Hodgson, and several other eminent inquirers, have expressed themselves differently,—viz., that aneurism may exist where there is integrity of the walls. Amongst those holding these views may be cited the names of Sabatier, Nägele, Ackermann, Breschet, Boyer, Dubois, Dupuytren, and Lisfranc, who arrived at their conclusions not from theory, but actual dissection. We can readily imagine that an artery may assume a disease by which it shall lose its natural elasticity, and become softened and expanded; if, however, this dilatation should progress to any considerable extent, the inner tunics will invariably give way. When these tumours are simple dilatations, they are then soft, and if externally situated, can upon pressure be emptied of their contents; but when the inner coats divide, fibrous lamellæ are deposited, at the first but to an inconsiderable extent at the inequalities formed by their corrugation, then increasing, and thus by an accumulation of fibrous deposition, constantly becoming augmented, the tumour acquires a resistant consistency, which constitutes the second stage. It has been questioned by certain authors whether we can with strict propriety term that condition of the vessel—simple expansion of calibre, or even unequal distention of the walls, so long as their entirety continues—aneurism, because the lamellæ are not deposited. In this man, as reported, in the earlier stages of the swelling it was soft, and could on pressure be relieved, but when the layers of fibrin began to form, it acquired the resistant characteristics described. The deposition of fibrin, as remarked, never forms so long as the lining membrane is whole, for then none of the fluid passing along the canal can be carried out of the circulation, and it is in this stage of the tumour, when organizible matters are deposited in its cavity, that sometimes nature, by totally filling up the dilated sac, effects her own cure. When, however, an aneurism is in the large vessels, near the heart, the impulsion of blood is too great, and the current too much agitated, to allow the requisite quiescence for organization to proceed, and complete solidity result. The external coat, so called, is on account of its cellular filamentous texture, far more distensible than the others, and thus it forms an expanding basement to the fibrinous lamellæ as the depositions increase, otherwise aneurismal tumours would attain but an inconsiderable size

before their contents were freely poured out, and of course, if internally situated beyond the surgeon's reach, death would ensue.

On a review of this case, some facts worthy of notice present themselves. In the first place a lesson is supplied that we can never be too precise and careful in our examinations of disease. Here was an affection of the gravest character, considered and treated as mere rheumatism; the man had been allowed to prosecute his work, which of course, by exciting the circulation, would tend to the aggravation of his affection; the blisters and plasters by which he was treated, were manifestly mis-directed applications.

All writers agree that males are more subject to aneurisms than females; indeed in a table drawn up by Hodgson, out of a totality of 63 cases, 56 were males and but 7 females! These were all examples of spontaneous aneurism. The experience of Sir Astley Cooper, Mr. Guthrie, Lisfranc, and others, bears testimony to the same. In accounting for this, it would be less correct to attribute it to congenital proclivity or natural tendency, than to the operation of causes, incident to the habits and kind of life in males. The greater exertions—more violent exercise—the many causes of excitement to which men are in various manners exposed—the very potent predisponent, intemperance, in which they so often indulge,—all generally tend to render prevalent this disease, more in the one sex than in the other.

Aneurisms, when they do appear, generally come on at an earlier period in life than in this man. Out of 120 cases given by Lisfranc, 108 were before the age of 55, and that author has shewn that from 30 to 35 is the period at which the greatest liability to their occurrence exists. When we reflect upon this fact, it seems a probable one, because at that age the vascular function is carried on with great power and force; in the meridian of life, great physical exertions are often and willingly performed, and because at that time there is often a plethoric condition, and then all those various causes of vascular excitement are in constant operation.

The larger vessels are more prone to the affection than the smaller, because the impulsion of the column of blood is more forcible, the nearer they are situated to the heart, just as a body is propelled with more force and celerity when it is first thrown into motion, than when it is becoming quiescent from the influence of resisting media, (a law which similarly obtains relative to sound,) because the walls of the larger vessels are not thick in proportion to their calibre—that is, when comparing them with the smaller vessels, and because in the larger vessels, especially the thoracic, there are more curvatures.

The stethoscopic idications were very distinct, and in the examinations of these tumours auscultation should never be omitted, because aneurisms have existed when not suspected; and conversely, tumours which have received impulsations from large adjacent vessels, have been sometimes wrongly considered aneurism. Each systolic action of the heart distends the tumour, synchronous with the arterial diastole, and there is then impulsion on the walls of the tumour, which impulsion gives rise to the percussion-sound. Immediately after the percussion-sound, follows a slight thrill, termed fremissiment, the termination of which is synchronous with the arterial systole, and at the commencement of the ventricular diastole. M. Gendrin says there are, in the aneurisms of large arteries, two impulsive shocks—the one by impulsion against the parietes, the other following the retraction of the tumour and corresponding to the arterial systole, In tumours, not aneurismal, there are not two impulsions because the impulsive percussion, caused by the termination of the retractive action of the sac, cannot exist except in true aneurisms; where the impulsion is but a transmission from the pulsation of large adjacent vessel, there is only that isochronous with the diastolic arterial action. Fremissement and the second impulsive percussion are always distinct in the earlier stage of the swelling, and when the tumour has for some time existed, they are in a great measure or wholly lost, this being dependent upon the increase of fibrous deposition and infiltration of serum into the subcutaneous cellular tissue, and thus preventing the elastic contractions of the sac, and rendering the thrill less distinctly transmissible. The orifice* forming the communication between the sac and the vessel, is for the most part rough and irregular, and, at the arterial edges, are often found filamentous or pedunculated attachments; hence, from these bodies and the unevenness of the opening, the fluid in its ingress and egress produces vibratory sounds, exactly as we know this to be the case where there is morbid roughening or contraction at the auriculo-ventricular orifice, impairing the smooth transit of the column of fluid—hence, as noticed in the case, auscultation discovered a distinct bruit. If the opening between the arterial trunk and tumour is small, true synchronism between the aneurismal and arterial retractions cannot exist, owing to the tumour not momentarily becoming emptied of its contents. Attention to these physical signs, which are so pathognomonic of aneurism, will enable us to form a decisive diagnosis.

The increase of pulsation which there was in the

* Valvular vegetations have been known to produce sometimes loud and very extraordinary sounds. I recollect one of the Edinburgh Anatomical Lecturers mentioning an instance of this kind, in the person of a man, who some years ago was a patient in the hospital. The noise made by each ventricular contraction was a clear and distinct "cooing," and could be heard at two or three yards distance. The other inmates of the ward were much amused at such strange internal sounds, and they gave to him the name of the "cooing-man" After death valvular vegetations were discovered. Hope and other writers on the heart cite like instances.

right carotid, might of course have been anticipated from the extension of the disease to the juncture at the arteria innominata, thus giving rise to obstructed circulation in that vessel, because in all cases where there is considerable disease in the subclavian, and as in this instance, in which the pulsations were felt in an increased degree close under the sterno-clavicular articulation, it is fair to infer that the inferior orifice of the carotid branch would in some degree be occluded.

An œdematous condition of the shoulder could not otherwise than succeed the great impediment given to the return of venous blood, by perversion and distortion of the subclavian vein,—the numbness, declension of temperature, swelling and lividity of the hand, are most probable results. The complete cessation of the radial pulse is an indication of subclavian, as it is also of innominate aneurism; but in aneurism of the arch this is not the case. Mr. Barron, who gives a case of aneurism of the arteria innominata, mentions this fact:—"The pulse," says the relator of the case, "cannot be felt at the right wrist, nor can any pulsation be detected in the right brachial or subclavian arteries." It is often not very easy to decide, whether an aneurism be in the arch or in the innominata; when the radial artery ceases to beat we are led to conclude that it is the latter. In this man there were no bronchitic nor pneumonic attacks; hence, it is fair to presume the innominata was not enlarged, because when that vessel becomes tumid there is pressure upon the right bronchus, which gives rise to the diseases mentioned. Two or three weeks ago Professor Walshe shewed me a case of aneurism of the arch of the aorta then under his care in the North London Hospital, which I auscultated and carefully examined, and on the day on which these remarks were written, I had an opportunity of inspecting the morbid parts, the patient having died very suddenly some days ago. The man, during the latter part of his illness, had considerable dyspnœa, which morbid appearances fully accounted for. The lower part of the trachea was very obviously flattened, so much so, that the elastic fibrous membrane at the posterior or vertebral aspect of the rings, which joins their extremities, was obliterated by the continuous lateral pressure on the trachea; but the bronchi were natural, which would not have been the case on the right side if the innominata had been enlarged. Speaking of this man, (the hospital case,) it may be here mentioned, that during life, slight prominence was perceptible at the cartilages of the second and third ribs, and on inspection, the clavicle and first rib presented ulcerous erosions, of course consequent upon pressure exerted by the aneurism. Boyer and other authors allude to the destruction of bone by these tumours, and I have great reason to suspect that in the case of Armstrong, very extensive decay of the clavicle and first rib had taken place, because several weeks previous to his death, manipulation gave the feeling as if a roughened end of this bone were left by the process of ulcerative destruction, at the extremity of which it could be traced from the sternal end till lost in the tumour; it felt spiculated and abrupt.

Hospital Reports.

WEST NORFOLK AND LYNN HOSPITAL.

COMPLICATED SURGICAL INJURIES UNDER THE CARE OF CHARLES COTTON, ESQ., M.D., F.R.C.S., &c.

GUN-SHOT WOUNDS OF THE HEAD AND WRIST; AMPUTATION OF FORE-ARM: DEATH ON THE FIFTY-SEVENTH DAY FROM THE SECONDARY EFFECTS OF LESION OF THE BRAIN.

Edward Bulman, 17 years old, admitted Sunday evening, May 7th, 1848.* Brought a distance of eight miles to the hospital. Reported to have left his employment as "crow-keeper" for the purpose of shooting rabbits, and whilst drawing his gun with the muzzle towards him, to have acidentally discharged it; the accident occurred late in the afternoon. The charge had perforated the right wrist, lacerating and shattering the bones and soft parts, and also inflicted a large ugly wound in the left fronto-temporal region. The external orbit and temporal arch were found fractured and comminuted; the left eye started from its socket; the lids pierced with shot, swollen, and ecchymosed; the cheeks and nose grazed and disfigured; and the right eye suffused and closed. The boy was in a confused comatose state; the surface of the body warm, and the pulse not much enfeebled. Amputation of the fore-arm being approved in consultation, Mr. Cotton proceeded at once by flap method to remove the limb at its centre, making the posterior semi-circular incision by cutting from without towards the bones, and the anterior by transfixion. The patient was much roused by the operation, and on a momentary difficulty being experienced in securing the interosseous artery, lustily begged it might soon be completed. The face, and wound of the temple, were afterwards sponged and cleansed, the hair removed, and the head directed to be kept cool by frequently renewed applications of cold water.

May 8th. Comatose and stupid; pulse slow; passed a tolerably quiet night; unconsciously elevates and moves about the stump, and cannot be made to keep it on the pillow without constant attention of the nurse. Give only cold water, should anything be desired.

9th. Somnolent and heavy, but replies to questions on being roused.

* A man was admitted into the hospital under Mr. Cotton, on Sunday evening, December, 4th, 1841, with almost precisely the same injuries from a gun-shot wound, for which the arm was amputated, and the left eye perished. Recovered without a single disagreeable symptom.

11th. Less drowsy; complains of the wound, which is ragged and offensive. Warm water dressing applied.

13th. Answers rationally; wound of the head granulating; bone denuded and rough. To be allowed milk, in the place of water; and to have as a cooling aperient occasional doses of citrate of potash.

14th. Arm uneasy; bandage removed, and an exit given to a quantity of sanio-purulent matter; continues to raise and move about the stump unconsciously; bowels moved by an injection. To go on with the cold applications to the head, warm water dressings to the wounds, and let him have six ounces of bread with his milk daily.

22nd. Can open the eye-lids a little; conjunctiva turgid and chemosed; and vision of left eye gone. Ulnar ligature came away. Middle diet.

24th. Stump wound granulating and healing; remaining ligatures withdrawn; wound of the temple discharging purulent matter, in which some small bony spicula were observed.

27th. Partial ptosis of left eye; cornea opaque and hazy; pupil irregular, and as if part of the iris externally had been shot away. Convalescing satisfactorily, but still apply occasionally cold water to the head.

31st. Vision returning; wound of head much reduced; granulations exuberant, but pale and flabby. Apply a weak solution of caustic.

June 4th. Sight more complete; can distinguish objects, and open the eye better; conjunctiva and cornea clear.

7th. Pale, feverish, and sickly; stump as usual, cocked up, and apparently unsoundly healed; the limb above loaded and œdematous. Diet reduced. Arm bandaged, and hot linseed poultices applied to the stump. Potassæ Citratis, dr. j., pro re nata actu effervescentis.

10th. Œdema subsiding; stump again discharging.

17th. Feels very well, and enjoys his middle diet; stump firmly cicatrized. The peculiarly elevated state of the damaged arm, particularly remarked. Head wound stationary, attributed to the exfoliation of bone. From this period, there being no prominent symptoms, the case attracted but little attention, until the 26th, 27th, and 28th, when the patient was observed to be dull, heavy and taciturn, and the appetite was found to be slightly impaired. He makes no complaint, however, and the nurse cannot be convinced that anything is amiss, and attributes his looks to the fright and anxiety caused by a man in an adjoining bed suffering from traumatic delirium.

29th. Headache in the night; frequent rigors, followed by profuse sweats.

10 a.m. Comatose and insensible; pupils widely dilated; pulse 120, hard. Hirudines vj. sub aures singulas applicentur ac postea fotus calidus.

Vespere. The leeches have relieved the drowsiness, but there has been extreme restlessness ever since; looks anxious, wild, and vacant; is constantly raving and disturbing the other inmates with his cries and screams; when questioned says he is in great pain about his back and shoulders. R. Liq. Opii Sed., (Battlei,) m. v.; Spt. Æth. Sulph. Comp., m. x.; Mist. Camph., oz. iss. Fiat haust. statim sumendus, dosisque repetatur omni secunda hora, vel ut opus sit. Cold to the head.

30th. Much quieted, but yet anxious, fearful, and drivelling. Cold applications to be discontinued as they disturb and excite him. Rep. haust. ter die tantum.

July 1st. Much in the same state, but more weak; perfect control over the sphincters.

2 p.m. Became furious and noisy for a short time, when he fell into a state of profound coma, and died on the following morning, apparently from mere exhaustion.

Post-mortem. Scalp and sub-tegumentary tissues around the seat of injury dark and discoloured; three shots turned out; a deposit of new bone about the fractured parts; the left cerebral meninges thickened and opaque, and the hemisphere upon the surface ulcerated from the presence of flattened shots. Pus effused in considerable quantity, extending down to the orbital plate of the frontal bone, which had been fractured and raised; sinuses and veins distended; ventricles dry and destitute of serum; brain otherwise firm and healthy.

Remarks.—The leading features of this case show in the first instance,—concussion in a mild degree, from an injury of no common violence, gradually subsiding under severe abstinence and the use of cold applications. On the 31st day, febrile action accompanied with a phlebitic state of the stump and arm, yielding to local pressure, and convalescence seemingly proceeding rapidly, and the case attracting but little attention until the 53rd day, when the occurrence of lethargic symptoms, preceded by slight general *malaise*, gave intimation of secondary mischief going on in the brain. This state, under subdepletory measures, was followed by one of excitement and debility, and finally, just as the powers of life were ebbing, by profound coma.

The *post-mortem* inspection developed inflammation and disorganization of the surface of the brain, arising from the lodgement of foreign bodies, and shewed, moreover, how little implication of the different nervous centres may result from lesion confined to the cerebrum. The details of the case taken with those relating to Ferdinand Hess,* though establishing nothing new, are not uninteresting, but forcibly illustrate the difficulty of distinguishing, with any certainty, the nature and extent of head injuries, and the necessity of a guarded prognostication of after-consequences.

* *Provincial Journal*, No 18, 1847.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, SEPTEMBER 20, 1848.

We have been favoured with a copy of an elaborate Report, just issued by the Council of the National Institute of Medicine, Surgery, and Midwifery, "on the Present State of the

Medical Reform Question." The Report professes to give an historical sketch of the progress of this great question, in which, were we so disposed, we could point out some serious omissions, tending to deprive it of the claims it might otherwise possess to consideration as a clear and impartial statement of the circumstances which have gradually led to the present position of Medical Reform. We are rather desirous, however, during the interval which must elapse before the subject can again come before Parliament, and, as we hope, attain a final settlement, calmly to review, as occasion serves, the present state of the question, its bearings on the different bodies of the profession, the recommendations of the Committee of Conference, and other points of interest to the entire medical profession connected with it, and in fulfilment of this purpose the Report will furnish us with ample and valuable materials.

The most important of these materials are, the Principles of Medical Reform, agreed to by the Conference, already printed in the Journal,—the Draft of Charter proposed to be granted to the General Practitioners,—and the Outline of a Bill for Regulating the Profession of Physic and Surgery, drawn by the Conference. The objection urged against the proposed measures by various parties, and the remarks in reply to them, will also require attentive examination. On each and all of these points we shall have frequent occasion to refer to the information brought together from various sources, and embodied in the Report, which, in every point of view, cannot but be regarded as one of the most, if not the most important documents yet contributed towards the elucidation of the entire subject.

Leaving the details connected with the former progress of Medical Reform, the origin of the conferences, &c., we shall proceed, at an early opportunity, to the consideration of the results. These results, as coming from the governing bodies of the Colleges of Physicians and Surgeons, the Society of Apothecaries, and the National Institute, may be considered to have received the assent of each of the parties represented—that is, of the Council or ruling power of each; and in so far as these Councils or ruling powers are the representatives of the great divisions of the profession, of which the respective Colleges and Societies are composed, of them also. But though the Council of the Institute of Medicine, may fairly be assumed to represent the opinions of a very large number of general practitioners, can the same be predicated of the Council of the Royal College of Surgeons, as regards the members of that body? or of the Fellows of the Royal College of Physicians, as regards the physicians of England? Certainly not, and a sufficient proof of the fundamental defect in the constitution of the Committee of Conference, which renders it most essential to subject the whole proceedings of that body to a searching scrutiny, is afforded by the unsatisfactory state in which the privileges of the entire class of physicians, not Fellows of the College, were left. The licentiates of that body, both *intra* and *extra urbem*, and nine-tenths of the physicians practising in the country, were thus not represented in the Conference; and their interests, in consequence, completely sacrificed. Happily, the physicians of England were, at the instance of the Council of the Provincial Medical and Surgical Association, induced to come forward and state their objections to the proposed Charter of the College, as it had been agreed to by the Committee of Conference, and their remonstrances embodied in a memorial to the College, and presented through the Council of the Association, were listened to with respect, and the Charter so amended by the College authorities, as to meet the wishes of nearly all those whose interests were concerned.

Now, whatever may be the provisions of the measure proposed for the incorporation of the general practitioners, it yet remains to be ascertained whether those gentlemen belonging to the class, who have not yet enrolled themselves members of the National Institute, are disposed to agree to it; and still more with respect to the general measure, as laid down in the outline of the bill agreed to by the Conference, whether all who have not been parties to the Conference by their authorized representatives, or at least a considerable proportion of them, are content to receive it as the future legislative

enactment for the government of the whole profession. The entire body of the *Members* of the College of Surgeons was left unrepresented in the sittings of the conference. Are these gentlemen satisfied with the results of the Conference, as respects their position in their own College?—are they satisfied with the provisions under which it is proposed to place the whole profession. Lastly, are the existing licentiates of the College of Physicians, of whatever description, and the physicians of England, not members of the College, content to receive the proposed Bill? These are questions which yet remain to be answered, and in respect to which the propositions agreed to by the Conference yet require careful examination, before the entire profession can be said to be agreed on the principles of the general measure, and, consequently, before it can, either as a whole, or in any of its parts, be pronounced to be satisfactory. These questions we propose hereafter to examine, and with the assistance of the Report, to point out what further, if any, modifications are required in the several conclusions come to by the Conference.

Review.

On the Cure of Cataract, with a Practical Summary of the best Modes of Operating, (Continental and British.) By Hugh Neill, Surgeon to the Liverpool Eye and Ear Infirmary. 1848. pp. 224.*

In reviewing the opinions of different writers on cataract, British and foreign, including Lawrence and Mackenzie, the author exposes the error into which they have fallen, by representing absolute blindness to arise from some complication,—as amaurosis, with disease of the lens, instead of attributing it to disease in the lens alone. Cataract may be produced, according to the author, in the following manner:—

"*First.*—By defect of nutrition. It is this form which generally affects old men. The vessels which come from the *body* and *ciliary circle* become by degrees totally obliterated, the crystalline ceases to vegetate, and in the effluxion of time, dies.

"*Secondly.*—By an inflammation, which, having its situation in the capsule, has not terminated in resolution. This is the cataract which affects children and adults. It is supposed that this pathological state, by diffusing the nutrition of the crystalline, prevents it afterwards resisting the *opacity*, which is only an after-result." p. 77.

Having enumerated the usual diagnostic marks of cataract, the author notices that of Professor Sanson, usually denominated the *three lights*. When this experiment is tried, the pupil should be dilated with belladonna before the candle is produced, otherwise the surgeon may be disappointed. The eye should also be examined in total darkness.

Most writers have insisted on the necessity of selecting the spring as the most favourable season for operations for cataract. This is considered by our author as an absurd prejudice, and a wanton trespass on the feelings of the patient; spring being in his opinion, from its constant vicissitudes, the most ineligible season for an operation.

Surgeons appear to differ much in their opinions respecting their propriety of operating on both eyes on the same day. Except under peculiar circumstances, we have always adopted this plan, and our success has been uniform; and we believe all the best operators of the present day adhere to this rule.

In alluding to what has been called *black cataract*, the author relates the following case, which, on account of its rarity, we extract for the notice of our readers.

"I have at present under my care, one of the most curious cases of cataract which has hitherto fallen under my notice. The young lady has large well-formed eyes. The irises ('irides') are dark brown; the pupils very moveable and of natural size. She has for many years had imperfect sight of the left eye, which now is nearly blind; her right eye is also becoming gradually dim. On examining the pupils with the microscope, there is a deep-seated opacity of a very dark brown—a brown black. Sanson's test with the taper gives only one light. Upon dilating the pupil a large central opacity is seen in both eyes, but larger and denser in the left eye. The capsule seems tolerably transparent in the centre, and opaque white dots are to be seen at different places round its outer edge; but they are only visible when the pupil is dilated to its widest extent. The microscope shews the opacity of the lens to be covered by minute deposits resembling myriads of little dots of the darkest brown colour."—pp. 169, 170.

Both Mr. Guthrie and Mr. Lawrence, neither of whom believed in the existence of black cataract, admitted when they saw this case, that it might have been considered a specimen of the black cataract of authors. The discolouration has been attributed by some to melanosis, and by others to the deposit of manganese. The author thinks it owing, in this case, to oxide of *iron*.

After some lengthened and sensible remarks on Sanson's three-light test, which the reader ought to consult, the author proceeds to consider the operation for cataract by *reclination*, and compares it, as an operative proceeding, with extraction for the removal of the hard species of the disease. The necessary dexterity of the surgeon, which can only be acquired by sad experience, and with certain favourable conditions of the eye itself, which are requisite to ensure success, being duly considered, the author prefers reclination to any other operation, except in those patients who manifest a rheumatic tendency. The author's process is the following:—

* Continued from page 492.

"The operator, while he fixes—say the patient's left eye, with his (the operator's) left hand, the process is done thus—and I am supposing that the speculum is not used:—The second finger raises the upper eyelid and fixes it against the eye-brow. The first finger depresses the lower lid. The eye is thus firmly enough fixed: its outer portion is free enough to be punctured, and there is no impediment to a thorough inspection of the pupil. A *flat* straight needle, with two cutting edges running to a point is carried, at the eighth of an inch from the cornea, towards the very centre of the eye, through the sclerotic. The needle must not be poked into the lens. As soon as it is judged to be behind the *iris*, it should be gently forced, to the anterior of the lens, and posteriorly to the iris, *forwards* towards the pupil. The point of the needle seen in the pupil is now to be depressed, and *pressed down* the face of the lens to its lower edge, and carried back *below the lens* right into the vitreous humour. The needle is then moved horizontally backwards and forwards, so as to cut a free course in the vitreous body for the passage of the lens. All this is *continuous*, momentary, and essential movement. Attempted otherwise, a laceration of the vitreous capsule is not easily accomplished; and should the membrane be tough and not lacerated, the lens may be turned topsy-turvy, and tilted into the anterior chamber.

"The needle having made its way through the capsule of the vitreous humour, now comes back to the anterior of the lens. The lens now moves downwards. The needle passes down also, and the lens begins, technically to *recline*; that is to say, it turns backwards.

"The needle ought to get on the (now) top of the lens; and away it goes, launched as it were into the vitreous humour.

"It only remains for the parts to become adapted to this new position, and the case will be as brilliant as the most enthusiastic eye-surgeon could desire."—pp. 185, 186.

We have before stated that the cataracts occurring in rheumatic persons are not so well adapted for this operation as for extraction. These may be known by their brown or amber-colour; and the previous history and the constitution of the patient ought always to be ascertained.

The proper position of the patient having been disposed of, and a well-merited compliment having been paid by the author to Mr. Guthrie, whose masterly operations for, and writings on, the extraction of cataract, have established his reputation throughout the world, we next observe some remarks on the absorption of extraneous substances introduced into the eye, which Desmarres erroneously conjectured might take place. This writer very cooly advises, "should the point of the instrument break, leave it in the eye for absorption." It may be perfectly proper to leave a small portion of broken steel in the eye, but it is absurd to expect its absorption. Mr. Neill says, "I have seen pieces of shining steel in the cornea, which had been imbedded there, unchanged, during half a century."

The author makes a short digression, for the purpose of pointing out to the profession the probable advantages which may be obtained in the treatment of some other diseases of the eye, by the application of *veratria*, in consequence of the property it possesses of procuring the contraction of the iris. He thinks its operation is that of a stimulant, and that it may be found beneficial in cases in which it is our object to diminish the admission of the rays of light, as in a disordered state of the retina.

The skill and extraordinary success which Mr. Neill has displayed in the performance of operations on the eye, and especially of his favorite and safe operation by reclination, have placed him in the highest position as an ophthalmic surgeon. From our own experience in the operation of reclination and other proceedings with a properly constructed needle, we venture to say that extraction of the lens will in future be very rarely required; and if Mr. Neill had conferred no further benefit on the public than that of attracting the attention of the profession to the safe and certain expedient of reclination, whereby innumerable eyes will be saved in future from the destruction occasioned by inexperienced operators, he would have deserved the highest commendation. In conclusion we must add that Mr. Neill's book is replete with practical information, and should be read by every surgeon-oculist.

J. M. C.

INQUEST ON A CASE OF ALLEGED POISONING BY BELLADONNA.

The following account of an inquest held on the body of Thomas Greaves, whose case was communicated by Mr. W. Jackson, of Sheffield, to the Anniversary Meeting of the Provincial Medical and Surgical Association, held at Bath, is important in many points of view. The inquest was held at the Town-Hall, Sheffield, on Thursday, July 6th.

Hannah Greaves, widow of the deceased, examined.—I live in Love-lane, Sheffield. My husband was 76 years of age, and formerly a silversmith. He was lately in the habit of assisting Mr. Butterworth, a publican, in Fargate. He was an out-patient of the Sheffield Infirmary, and had been there twice. He went there on Tuesday last, the 4th of July, about nine o'clock, and returned home about eleven in the forenoon. He brought from the Infirmary a box of pills, some ointment in a box, and a plaster. The ointment was of a black colour. He would not take any of the stuff till Mrs. Taylor came. She came about from five to six in the evening. I saw him take a pill out of the box, and also a small portion of the black stuff out of the box. He took it with his own fingers, and said he was to take it, but there were no directions. There was no reading nor direction on the pill-box or the ointment-box. He went to bed about seven o'clock. Before he went to bed he seemed dilatory about undressing himself, and his speech was gone. He took his breath very hardly and rattled, and got worse and worse all the night until the morning. We never had our clothes off during the night. He complained all night of inflammation of his breast, and that he could not get his breath well. He died next day at eleven o'clock in the forenoon. He never spoke to me

all the night. Just before he died he began to vomit, and asked my daughter for me. I asked him if he wanted anything, and he said no. He was convulsed all night. Mrs. Taylor put the plaster on. I think the stuff my husband took was not so big as a pill. I cannot say whether he used a spoon or a knife on the occasion. He could read a little. Neither of my daughters saw him take the physic.

Martha Taylor, midwife, wife of James Taylor, of Love-lane, shoemaker, examined.—The deceased went to the Infirmary on Tuesday morning last. He brought from thence a plaster for his stomach, some pills, and an electuary. He had had a strengthening plaster on before, and he was to bathe it with warm water, then take it off, and put the other in its place. This was the one he brought that morning from the Infirmary. I saw both the boxes. There was no label nor direction on them how to take them. He had his printed Infirmary paper with him, and another with a prescription on. He asked me how many of the pills he should take, and I told him to take only one of them. He did so, and afterwards took a little bit of the black stuff out of the other box. He got it out of the box with the end of a tea-spoon; it was only a little bit. This was between five and six in the evening. About nine o'clock, I went into the house, and saw him sat on the bedside trembling. He could not speak. I saw him three or four times between six and nine o'clock. He was then in bed, and appeared to be asleep, and to take his breath very thick. I did not see him again after nine o'clock. I did not observe before I left him that he was convulsed. He lay very still when I saw him, but he moaned very much when sat on the bedside about nine o'clock. I don't think he was then sensible. He told me that he was to take the pills in the black stuff or "electuary," as he called it. I am sure he called it "electuary."

Eliza Greaves, widow of William Greaves, and daughter of the deceased, examined—I live in Eyre Lane. I went on Tuesday night last, about seven, to my father's house, and found him sat on the bedside. I asked him how he was, but he could not speak. I asked my mother why my father did not get into bed, as he was a long time undressed, and she said, "Tommy, get into bed; thou'll get cold." I again asked him how he was, when he tried to speak, but he shook his hands about and could not utter a word. He kept knocking his hands and feet about. I left at half-past nine and returned about ten, when he was very hot, and his face seemed red and swollen. He continued knocking his hands about, but kept his feet stiller. I left him at half-past twelve, when he was insensible. I returned to the house at nine next morning, when, thinking he was much worse, I fetched Mr. Pearson, surgeon, of Bank Street, and then went home. I did not see him take any of the stuff. I asked my mother what had made him so ill, and she said he had taken a pill and some ointment, which Mrs. Taylor had given him. His sight was very bad. I saw Mrs. Taylor give my father, about half-past seven, about an ounce of castor oil, which Mrs. Taylor said would perhaps send the stuff he had taken through him. Mrs. Taylor gave him the pill and the ointment, and he took it.

William Hudson, porter to the Sheffield General Infirmary, was then called. Being duly cautioned by the Coroner that he need not say anything to criminate himself, the witness made the following statement:—I have been porter to the Sheffield General Infirmary ten years and a half. I gave Thomas Greaves his medicine on Tuesday morning last. I gave him a plaster and a box of belladonna. I gave him directions how to take the plaster and the box—to spread what was in the box on the plaster and apply it to the part affected. I was very particular in giving him directions, as he was an old man. I told him the directions twice over, and said, "Do you properly understand what you have to do with what is in the box?" He replied that he perfectly understood it. I also gave him a box of pills, with the direction on the box, to take two pills three times a day. There was a label on the box of pills when I gave it to him, although there is none on now. I do not know the quantity of belladonna that I put into the box. The reason why I did not spread the belladonna on the plaster was, that, as he was an old man, I thought he had better spread it himself when he got home. The plaster would not have been of any use to him if it had been spread at the Infirmary, as he would have squeezed it together. I gave no written or printed directions on the box of belladonna, as to its use, because I had told him it was to be put on the plaster, and he knew perfectly well what it was for. He had not used it before. I know that belladonna is, to a certain extent, of a poisonous nature. Mr. Oakes, an assistant, was in the Infirmary surgery when I gave Greaves the stuff. Mr. Oakes and I had to deliver medicines to about 900 patients that morning. We have never had a direction for the use of belladonna as a plaster; when used in any other way there is a direction. Mr. Law has always said to me, "Send out a proper direction with everything." We never did give any other than a verbal direction with belladonna as a plaster. It was not from inattention to my duties or idleness, that I did not spread the belladonna, but from regard to the welfare of the old man. We have never had a mistake with belladonna before, and it has been sent out in this way for ten years. I think it was not my duty to spread the belladonna on the plaster, but to send it out as we had done before. I know that belladonna is an expensive article, and I think there was not more in the box than was necessary for the plaster. I am very sorry that the circumstance has occurred, but I will take care for the future that belladonna is not sent out in that way again. We have no labels marked "poison."

The Coroner—You ought to have.

Witness—When we have anything of poison, we write a label.

The Coroner—That is not proper. Did you write one on this box?

Witness—No.

The Coroner—You ought to have printed labels.

By a Juryman—There was no mention of an electuary, nor did I call the box of belladonna an electuary. Had it been an electuary, I should have put it in a pot, and not in a box.

Nathaniel Pearson, surgeon, examined—I was called in on Wednesday morning at half-past nine to attend the deceased. I found him in a dying state, gasping for breath, and, as I considered him, past the aid of remedies; I therefore did not administer anything to him. I left him about ten, and he died in about an hour after. I have since, assisted by Mr. Wm. Jackson, made a *post-mortem* examination of the body of the deceased. Externally, the body presented a somewhat emaciated appearance,

and there were no marks of violence. The vessels and membranes of the brain were highly injected, and the larger vessels distended with dark-coloured blood. The cavities of the brain were also distended with serous fluid, and the substance of the brain itself was softer than natural. The spinal canal was distended with a similar fluid, and its vessels highly injected. The stomach appeared in a natural state, both externally and internally, except at the upper part of the larger curvature, internally, where the mucous membrane presented a blackened appearance, of the size of the palm of the hand, indicating a state of incipient mortification of the part. The abdominal viscera otherwise presented no unhealty appearance. The heart was quite natural in appearance; the lungs in an uncollapsed state, and much darker in appearance than natural; they were filled with air, arising from an obstructed condition of the respiratory organs. The bladder and the intestines were perfectly healthy. I ascribe the death of the deceased to the effects of a narcotic poison. Belladonna would produce precisely the appearances which we found in the organic structures after death. I should say the quantity alleged to be taken, as on the paper produced, contained four grains. Belladonna is so seldom given internally, that it is difficult to state the smallest amount that would produce death. I think that five grains, under the circumstances of the advanced age of the deceased, and the disordered state of the chest, would produce death. The pupils of the eyes of the deceased were considerably dilated. I do think, without doubt, that, in this instance, belladonna has been the cause of death. Taking the state of his health, before he took the dose, into consideration, and comparing that state with the symptoms after taking the dose, and further observing the evidences of disease after death, I am quite convinced death was produced from narcotic poison, and no other cause. Mr. Jackson fully concurred with me in opinion as to the cause of death. The box contained five drachms of the extract of belladonna, which was more than was necessary for the plaster produced. Belladonna is a medicine very uncertain in its operation.

At the request of the Coroner, the inquest was then adjourned to Wednesday, July 12th. The following is the evidence then given:—

Mr. William Jackson, surgeon, Sheffield.—I did not know Thomas Greaves, the deceased. On Thursday the 6th instant, I assisted Mr. Pearson in making a *post-mortem* examination of the body of a man in Love-lane, who appeared to be upwards of 78 years of age. [The witness corroborated the evidence given on the first inquiry by Mr. Pearson, as to the appearances of the body when so examined.] I have no doubt but that the congested state of the brain, and the effusion of fluid in the cavities of the brain at its base, as well as in the spinal canal, produced the death of the deceased. The appearances might arise from the excessive use of spirituous liquors; the action of a narcotic poison; or it may have arisen from the peculiar state of the brain arising from natural causes. If I am to take for granted the evidence given by Mr. Pearson, as to the symptoms previous to death, and the statement he has given on oath, I should say death arose from a narcotic poison. Connecting that statement with the appearances we found after death, we are justified in stating that he died from a narcotic poison, but I cannot swear it was belladonna. If I had not been made acquainted with the symptoms during life, I should not have been able to state positively the precise cause of the death of the deceased. The effects of belladonna are pretty certain if it be pure, but they may be modified by peculiarity of the constitution of the person who takes it. I never saw a fatal case before of poison produced by belladonna, if this is to be considered one. I cannot undertake to say what would be the minimum dose that would produce death. I have given belladonna extensively in practice; but I do not remember a case in which I could safely give more than two grains. I think if I had seen the patient an hour before he died, I should have made an attempt to relieve his stomach of the poison. I think the friends of the deceased were highly culpable in not sooner applying for medical aid, as it is probable his life might have been saved. In the interval of from six o'clock in the evening till nine next morning, the belladonna would be absorbed into the system. The blackened state of the stomach of the deceased is a strong corroboration of the person having taken some poison. I cannot say that the deceased died from the use of spirituous liquors. From the mere examination of the brain it would be impossible to say from what cause he died. A large dose of belladonna, if pure, would certainly produce death. It is of great importance in a public institution that the medicine should be genuine. I have no doubt the drugs are obtained from a respectable dealer. The action of belladonna is upon the nervous system, and produces stupor, sleep, delirium, paralysis, and loss of articulation, which are the mode of death. If I had been called in at ten o'clock at night I might have saved his life.

Mr. Henry Oakes, dispenser of medicine at the Sheffield Infirmary.—I have served an apprenticeship to a chemist and druggist. I did not know the deceased. He was an out-patient of the Infirmary. I did not hear William Hudson, the porter, give directions to him or any one else on Tuesday morning week respecting belladonna; nor did I see him put any in a box. The reason why the porter is allowed to give out medicines is because there is more work than one person can do. That morning we had to deliver medicine to 800 or 900 persons; I think additional help is necessary. Our orders are, not to send out medicines without written or printed orders: and they never do if I know it. It is not usual to send out belladonna in a box, if it is intended to be used for a plaster. If Hudson had given Greaves or any other person any directions about belladonna being spread upon a plaster that morning, I should have heard him, and prevented him doing so. I should not have sent belladonna in a box. I have never known it so sent out. I believe the belladonna was genuine. I think it is not possible that those directions should have been given without my hearing them. We have no labels with poison printed upon them. When we have no printed labels we write one, for poison.

Mr. Joseph Law, surgeon to the Infirmary.—Having heard the medical evidence, in which are detailed both the symptoms which preceded death, and the appearances which were observed on the *post-mortem*

examination, I am decidedly of opinion that the deceased did not die either from belladonna or from any other narcotico-acrid poison. I have not one word to say in justification of the manner in which this box, whether containing belladonna or not, was sent out of the Infirmary. I should have disapproved of its being sent out, even accompanied by the fullest possible either written or printed directions. It was done contrary to a well-understood order which I have given and frequently repeated. The dose of belladonna which (if this be a case of poisoning,) was given, was only four grains; now there is not on record one case in which either four grains, or any similar dose, produced death. On looking at all the authorities I could, ending my researches with this work by Taylor, printed in the present year, I find twenty reports of cases of poisoning (but not fatal,) by belladonna. In these cases I find the largest dose taken was one ounce, and that the doses varied (and the symptoms also,) from that quantity downward; but where the doses were very small, the symptoms were also trifling. There is not a fatal case of poisoning by the *extract* of belladonna taken internally, on record. There was in the case of Thomas Greaves, the deceased, dilatation of the pupil, but no insensibility of it, and dilatation without insensibility is not a sign of poisoning by belladonna. The first and most prominent symptoms of poisoning by belladonna were all absent. There was no dryness of the mouth and gullet, no difficulty in swallowing, no tumefaction, and, in the evidence of the medical witnesses, no mention is made of redness of the face, hands, or any other part of the surface of the body. Nausea, a common symptom of poisoning by belladonna, was not spoken to as one of the symptoms preceding death. There was the absence of that lively talkative delirium, which has characterized almost every case of belladonna poisoning, either by the extract, the root, the leaves, or the berries; and instead of these symptoms, it is my medical opinion that we had the symptoms, which usually result from that kind of effusion into the ventricles of the brain and spinal canal which was sworn to. The first medical witness stated that there was serous effusion in the ventricles of the brain, and in the spinal canal; but Mr. Jackson stated that this effusion was found in these situations, and also at the base of the brain. Now, serous effusion is quite sufficient to produce death; but, whether it exists in any or in all of these situations it is no sign whatever of poisoning by belladonna. There is one case, and only one, recorded, in which there was softening of the brain. The appearances, therefore, of the brain were not those of poisoning by belladonna. The tubercula quadrigemina are pointed out by a very high authority, Flourens, as being the part of the brain principally affected, and the condition of this part of the brain has not been alluded to either by Mr. Jackson or Mr. Pearson. We find a black patch as large as the palm of the hand on the upper part of the larger curvature of the stomach, and this black patch is sworn to as a patch of incipient mortification. M. Gauttier de Claubry had 180 cases of poisoning by belladonna berries; and he examined the fatal cases, but neither he, nor Beck, nor Taylor, nor any other authority whatever, make any mention of mortification in any organ or texture of the body as one of the symptoms of poisoning by belladonna in any form. Neither of the medical gentlemen who have given evidence here have seen a case of poisoning by belladonna, and all medical facts and pathological principles oppose the belief, that four grains of the extract of belladonna could produce, either in sixteen hours or any longer period, a patch of mortification in the stomach. I am quite aware that these authorities speak of rapid decomposition of the bodies killed with belladonna; but rapid decomposition of the whole body is neither mortification, nor in the remotest manner allied to it. A mortified patch of mucous membrane would not be black unless it were dyed black by some extraneous body. In all the cases I have witnessed (and they are not few,) the colour has been the colour of the secretions—generally yellow—sometimes grey, but never black; and I know that if the whole of the four grains swallowed had been applied to that part of the stomach, and if not one atom of it had been mixed with the secretions generally, it could not possibly have blackened so large a surface. It is my opinion that I ought to have had the opportunity of witnessing the *post-mortem* examination of the deceased; and it is my opinion that I have a right to complain that the opportunity was not afforded me. It is my opinion that a very small amount of mortification of the stomach, much smaller than the patch sworn to in this case, would have produced death; and it is quite certain that this mortification was not produced by belladonna. Belladonna was sworn to by the first medical witness as a narcotic poison simply—not as a narcotico-acrid poison. Now, it is only by its acrid property that it could affect the stomach at all, or produce any local effect whatever. John Bailey, the author of a very important monograph on the medical use of belladonna, says that he began his medical career with one grain and gradually increased it, but subsequent experience taught him that it was best to begin with three grains, and he adhered to that plan. I estimate the number of out-patients receiving medicine on Tuesday at about 400; I think that there is ample provision made for dispensing the medicines; and I think also that when I am in the Dispensary, directions might and would be given by another dispenser that I might not hear. I am decidedly of opinion that four grains of belladonna, given to the deceased, though labouring under a disease of the chest, would not produce death; and I am farther of opinion that in an old man, enfeebled, exhausted, and diseased, it would require a more powerful agency to produce serious organic lesion, than in a young, vigorous, and healthy person; the lower the vital actions, the more difficult it is to produce active morbid action; at the same time I admit that the old and feeble man would die under the production of more trifling organic lesions, than would be required to kill the healthy and vigorous subject. The deceased had a condensed lung; and the other appearances spoken to are sufficient to cause death. I think he died from

natural causes, and not from the effect of any narcotico-acrid poison. The prescription was not written by Mr. Overend, but by Dr. Thompson.

Mr. Pearson said he was sorry if he had committed any breach of professional etiquette in not inviting Mr. Law to be present at the *post-mortem* examination. It was not intentional, but arose from his being much engaged at the time.

The Coroner, after carefully reading over and commenting on the evidence, said, it appeared from the statement of Mrs. Taylor, that the deceased had taken but a very small bit of the black stuff out of the box, (meaning the extract of belladonna,) and on being desired to show to the Jury how much he had taken, it appeared, from the opinion of Mr. Pearson, to be only about four grains. Now, the dose for an adult varies from *one* to five grains. The extract, when taken in large doses, produces all the symptoms of a powerful narcotic poison; but it is stated in Taylor's and Guy's works on "Medical Jurisprudence," that there have been very few instances known of this poison proving fatal, and that patients have recovered from very large doses. A case is published by Mr. Clayton, where a man took forty grains of the extract, and recovered; and another case occurred at St. George's Hospital, under Sir B. Brodie, in which an ounce of the extract had been taken, and the person recovered. It is, therefore, pretty clear that it is a medicine, uncertain in its operation, and not so active a poison as its common name would imply, and is much less virulent than some of the other narcotico-irritant poisons. Christison, in his able work, states if the accident is taken in time, poisoning with belladonna is rarely fatal; for as the state first induced is *delirium*, not stupor, suspicion is soon excited, and emetics may be made to act before a sufficient quantity of the poison has been absorbed to prove fatal. In this instance, the quantity taken by the deceased being small, it did not produce that extravagant delirium common in these cases, but there were dilated pupils, and the other symptoms mentioned by the witnesses. Now, should not the friends of the deceased in this case, when they found the state in which he was, *soon after he had taken* the pill and the extract of belladonna, have *immediately* sent for a medical man, and not have waited till nine o'clock of the *following morning*, (when the patient was dying,) before they called in medical assistance? and should not the medical man *even then* have adopted prompt remedies, as his patient lived more than an hour *after* he saw him? The facts of the whole case are now before you in evidence, and if you are of opinion that the quantity of the extract of belladonna taken by Thomas Greaves produced his death,—and that the porter, William Hudson, in sending out that poisonous medicine *without proper printed or written directions*, shewed such negligence and disregard for human life, as will in your judgment, render it necessary that this case should be sent before a higher tribunal, I am afraid it will be your duty to find him guilty of manslaughter,—it being clearly laid down, that if a party is guilty of negligence, and death results, the party guilty of that negligence is also guilty of manslaughter. But if you should be of a contrary opinion, you will have to say whether the deceased came to his death "accidentally from taking belladonna by mistake," or that he died from natural causes. I do, however, consider it my duty strongly to condemn the loose and dangerous manner in which poisonous medicines have been permitted to be sent out from the Sheffield General Infirmary, by William Hudson, the porter, and to suggest to the proper authorities there, that, in future, the *porter* should *not* be permitted to give out any medicines, and that none should on any account whatever be sent out without full and proper written or printed directions. It also appears to me, that on account of the great number of patients at the Infirmary, competent additional assistance should be immediately obtained, properly to dispense the medicines prescribed.

The Jury fully concurred with the Coroner in his remarks as to the loose manner in which medicines were sent from the Infirmary; and they recommended the instant dismissal of the porter from his situation.

The Jury, after retiring for some time, returned the following verdict:—"The Jury are of opinion that there is not sufficient evidence to satisfy them that the deceased has died from the fatal effects of belladonna, and they, therefore, return a verdict that he died from natural causes. The Jury, however, blame the friends for not sooner calling in medical assistance."

General Retrospect.

PHYSIOLOGY.

ON THE ACTION OF THE OMO-HYOIDEUS.

The reputed action of these muscles, as is shown by reference to the opinions of Bell, Cloquet, Cruvelhier, &c., is, to depress the os hyoides and larynx. Mr. Skey regards this view as too exclusive, and refers to them a highly important and hitherto unacknowledged function,—viz., depression of the os hyoides towards the *sternum*, the action by which *sucking* is accomplished. In examining such animals as drink by lapping, and in which the formation of a vacuum in the mouth, as in the act of sucking is not required, Mr. Skey finds the omo-hyoideus invariably absent. Its attachment to the scapula is regarded as a matter of necessity, inasmuch as the clavicle and first rib are occupied by the scalenæ, &c.

To the law that no animal which lives by lapping has this muscle, Mr. Skey acknowledges the objection which arises from the fact, that such animals, when young, also live by suction, and this would appear to invalidate his explanation of the action of the muscle. He endeavours to avoid the difficulty, by supposing that the act of sucking in the young animal is effected by the tongue alone.—*Medical Gazette*, July 7th.

ON THE SIGNS OF DEATH.

From an inquiry into the circumstances by which apparent death may be distinguished from real death, M. Bouchut has ascertained that all forms of apparent death, especially those which are due to asphyxia and syncope, present, whatsoever be the diversity of their symptoms, one common character—namely, the persistence of the pulsations of the heart—which distinguish them from real death. A commission of the French Institute, appointed to inquire into the merits of M. Bouchut's investigations on this subject, report, that having repeated his observations and experiments upon man and animals, in which syncope has been carried to its utmost limits, they can fully confirm the fact that in all such cases the pulsations of the heart

continue, and may be detected by auscultation. According to M. Bouchut, the certain signs of death are of two kinds—immediate and remote. The immediate signs of death in man are—first, prolonged absence of the movements of the heart, as recognizable by auscultation; secondly, the simultaneous relaxation of all the sphincters, due to the paralysis of those muscles; and lastly, the flaccidity of the globe of the eye, and the loss of transparency of the cornea. In the opinion of the commission, these signs have not an equal value, the first being by far the best and most certain. For, if ever the movements of the heart are undetectable by auscultation, for a period of five minutes together, it may with certainty be concluded that death has ensued. Moreover, this cessation of the movements of the heart is always accompanied by two striking phenomena—namely, the arrest of the respiratory movements, and loss of sensation and of the power of motion. The second circumstance—namely, the simultaneous relaxation of the sphincters—admits of more doubt as a certain sign of death. The condition of the eye, the commission think, cannot with safety be taken into consideration as a sign of death. So that cessation of the movements of the heart is the only certain proof of the complete cessation of life. The remote signs of death are stated by M. Bouchut to be—cadaveric rigidity, absence of muscular contraction on the stimulus of galvanism, and the occurrence of putrefaction. These points are admitted by all medical jurists, and cannot be disputed. Since general putrefaction of the body, however, only ensues after the lapse of a considerable time subsequently to the manifestation of the other signs, it is not necessary to wait for its occurrence before pronouncing on the reality of death; consequently, all houses established for the purpose of keeping bodies until putrefaction commences, as is done in Germany, must be productive of no advantage. The commission also urges the necessity in all cases of entrusting to medical men the duty of deciding whether death be real or apparent; for by them only can the cessation of the heart's movements, the existence of cadaveric rigidity, and the loss of muscular contractility, be recognized and rightly estimated.—*Gazette Médicale de Paris*, Mai 31, 1848, and *Medical Times*.

PATHOLOGY & PRACTICAL MEDICINE.

TREATMENT OF HYDROPHOBIA.

Dr. Marshall Hall has the following in the *Lancet*, of August 5th:—

If a frog be subjected to the influence of strychnine, two events may take place.

1. If it be continually excited to spasm by the irritation of a probe, life becomes extinct in a very few minutes.

2. If, instead of being so irritated, it be placed in a cool place, as a cellar, and all excitement avoided, it as certainly recovers.

A third order of facts is one of extreme importance; the effect of strychnine is *not* one of a spasmodic condition, but of extreme *susceptibility* to spasm. This susceptibility resides in the *centre* of the spinal system, but each spasm is an act of reflex excitement.

In this last respect hydrophobia accurately resembles the effect of strychnine; may it not also in the first and second?

In hydrophobia the patient dies of asphyxia, from repeated closure of the larynx. Imagine this asphyxia and reflex excitement avoided, why should the patient necessarily die?

Upon this reasoning the author suggests that tracheotomy should be performed, by which means asphyxia would be prevented. The patient should then be placed in a spring-bed, and surrounded by net curtains, so as to prevent the currents of air, motion from the bed, &c., and thus avoid reflex excitements. Thus he believes that the patient might be kept from dying until the poison is eliminated.

PATHOLOGICAL ANATOMY OF THE KIDNEYS.

Dr. Gairdner terminates an elaborate memoir on the morbid anatomy of the kidney with the following deductions:—

1. By far the greater part of the pathological lesions of the kidney arise from, or are connected with, the exudation of oleo-albuminous granules into the interior of the tubes and epithelial cells.

2. The oleo-albuminous exudation is probably often preceded, and occasionally accompanied, by vascular congestion, but when the quantity of exudation is considerable, more or less complete depletion of the vascular system invariably occurs. This is a secondary result of obstruction of the *tubuli uriniferi*.

3. The oleo-albuminous exudation occurs in two chief forms. First, universal infiltration of the tubes throughout the organ; second, infiltration of particular sets of tubules, the rest remaining free. In this mode the granulations of Bright are produced.

4. There is no essential anatomical difference between the exudations in the kidney which are the result of chronic processes, and those which have been considered as the result of inflammation.

5. The capillary vessels of the kidney are subject to spontaneous obliteration, unaccompanied in the first instance by any visible lesion of the tubes, giving rise to the peculiar affection which I have called the *waxy degeneration*. This obliteration of the vessels is probably in all cases preceded by a state of congestion.

6. The consequence of the waxy degeneration is thickening and varicose dilatation of the tubuli throughout the organ.

7. The tubes of the kidney are subject to contraction and obliteration, in consequence of the desquamation of their epithelium, a condition resulting in atrophy, and complete disorganization of the organ.

8. The desquamation of the epithelium varies very frequently in all the other diseased conditions of the kidney. When sufficiently long-continued and extensive it produces contraction, and this indifferently, whether exudation be present or not. It is sometimes accompanied by vascular congestion in every stage of its progress.

9. The earlier stages of the exudation can only be discovered by means of the microscope. The progress of the waxy degeneration, on the contrary, is best traced by the unaided eye. The desquamation of the

epithelium is only to be discovered with certainty by means of the microscope, and is particularly apt to escape attention, under all circumstances, if the *kidney* only, and not the *urine*, be looked to. It results that careful investigation, both by the microscope, and the naked eye, both of the kidney, after death, and the urine, during life, are indispensable to enable the pathologist to determine with exactitude the presence or absence of disease.—*Monthly Journal*, August, 1848.

SURGERY.

DISLOCATIONS OF THE HUMERUS.

Dr. Goyraud divides dislocations of the humerus in an essay on this subject, as follows:—

Genera.	*Species.*	*Varieties.*
1. Dislocation forward	1. Sub-coracoid 2. Intra-coracoid	complete. incomplete.
2. Dislocation downward	3. Sub-glenoid	
3. Dislocation backward	4. Sub-acromial Here is found the situation for sub-spinous dislocations if such be demonstrated.	complete incomplete

All these dislocations, he observes, are produced primarily; it is only muscular action can transform to any other. This is evident to all those who have studied luxations of the humerus on the dead subject, and still we yet find in some recent works highly esteemed, that error of the school of Desault,—that *sub-clavicular dislocation is the most frequent consecutive to dislocation forward and dislocation downward.* Doubtless in order to arrive at the internal side of the coracoid process, the head of the bone passes beneath that process, but without stopping. The violence which produces the luxation, is the only cause of complete rupture of the capsule, and of the muscles which are inserted into the greater tuberosity; and in order that this rupture take place, it is necessary that the head of the humerus should be forced by the shock, even to the other side of the coracoid apophysis. But if the force make the head of the bone only to arrive beneath the coracoid process, it leaves untouched the posterior part of the capsule and the muscles which are inserted into the greater tuberosity—parts which retain the humerus at this point; and muscular action would never be able to draw the head of the bone beneath the clavicle. This intra-coracoid dislocation takes place primarily, the same as all the others; and the sub-coracoid luxation does not transform itself into the intra-coracoid, more than does the sub-glenoid transform itself into the sub-coracoid or sub-acromial form: the secondary displacements, have evidently been conceived by the surgeons who got an incorrect idea of the relative situation of the displaced head of the humerus, and the state of the soft parts surrounding. Thus M. J. L. Petit, believed that dislocation downward became dislocation on the same border of the scapula—a serious error which gave rise to the theory of secondary displacements. Is it surprising that with the idea that it can occur in sub-pectoral and sub-scapular luxations, M. Velpeau should have believed in consecutive displacements by muscular action?—*Gazette Médicale*, Juillet, 1re., 1848.

COMPOUND DISLOCATION OF THE KNEE-JOINT.

A boy, aged 11, got his leg entangled in the wheel of a waggon, while hanging on behind. He was found lying on a sofa in great agony, and on ripping up the trowsers the head of the tibia was seen completely exposed, having been thrust entirely through the soft parts covering the joint posteriorly.

By making extension, and at the same time flexing the leg, the luxation was reduced. The laceration was extensive, the whole of the joint and the popliteal artery being exposed. The integuments were brought together, and a compress and a roller were tightly applied, the limb being supported in a semi-flexed position. The inflammatory reaction was but trifling. The wound healed in six weeks, and the boy was able to walk with a partially anchylosed joint.—*Philadelphia Medical Examiner*, May, 1848.

USE OF GUTTA PERCHA IN CLUB-FOOT.

Mr. Lyon mentions the great service he has derived in the treatment of varus from the use of gutta percha bandages. His method of applying them is thus described:—

After dividing the tendo-Achillis, a procedure not always required, the limb is wrapped in a bandage of gutta percha, of the thickness of a penny-piece, softened with hot water the bandage is applied as is customary, with the common roller. The limb being thus encased in gutta percha, while it is still soft, it is restored to its proper form, and held for a few minutes until the bandage becomes perfectly hard, when the foot is retained in the required position.—*Monthly Journal*, August, 1848.

FOREIGN BODY IN THE AIR PASSAGES: EXPULSION AFTER FOUR MONTHS.

A child, aged six, was admitted by Dr. O'Ferrall into the St. Vincent Hospital, for cough and dyspnœa. Four months before admission the child was tickled while he held some pebbles in his mouth, when a severe and alarming fit ensued, and the child screamed with pain. From this period the breathing was observed to be laborious, and he became subject to occasional fits of coughing, accompanied by hæmoptysis.

Examination of the chest gave the following results:—Symmetry nearly perfect; slight prominence of the right side anteriorly, with slightly increased respiratory expansion; both sides clear on percussion. Vesicular murmur on the left infra-clavicular region; heart's sounds normal. Mucous rale on the left mammary region, most distinct behind, and two rales on the right side, but the vesicular murmur was puerile and exaggerated. The general aspect of the child indicated impeded respiratory function. Face sub-livid, expression anxious; no sweats. From these signs Dr. O'Ferrall determined,—

1. That there was bronchitis in the left lung, which did not implicate its upper portion, and which had not extended to the right side.

2. That the respiratory function of the left lung, though not impeded altogether, was modified in a degree which called for compensative action of the other, and it was probable,—

3. That the bronchitis was not idiopathic or ordinary, since it was limited to one side, and to a portion only of the lung.

4. That the bronchitis was not of tubercular origin, since it did not manifest itself in the apex of the lung.

There was, then, a localized inflammation, for which it was impossible to account without reference to the history, and Dr. O'Ferrall therefore did not hesitate to conclude that a foreign body was lodged in the left bronchus, without completely blocking up the tube. This diagnosis was confirmed by Dr. Stokes and others.

The question of operation which was now considered, appeared to Dr. O'Ferrall to depend upon the considerations of the chances of being able to grasp and extract the foreign body, and the probability of the occurrence of general bronchitis. In the case of Mr. Brunel, all attempts to remove the half-sovereign by the opening in the trachea failed, and it was at length expelled through the rima glottidis. Seeing the difficulty which occurred in this and other cases, Dr. O'Ferrall devised a pair of basket-work wire forceps, which might be introduced into the larynx through the artificial opening, and catch the body as it fell towards the glottis when the patient was inverted. Before, however, the operation was undertaken, the boy was suddenly seized with a fit of coughing, and the stone was expelled. From this time all painful symptoms ceased, all the treatment required being the application of blisters, &c., for the removal of the local bronchitis.—*Dublin Quarterly Journal of Medical Science*. May, 1848.

LIGATURE OF BOTH PRIMITIVE CAROTIDS.

An additional instance of this rare operation is recorded by Dr. Blackman, U.S.

A boy, aged 15, had what was supposed by a former attendant to be nasal polypus, and it was accordingly treated as such ineffectually. As it continued to increase, and gave rise to hæmorrhage, which threatened life, it was determined to tie the right primitive carotid, which was accordingly done. The effect was a temporary diminution of the tumour, which had invaded the cheek; but in the course of a fortnight he began to complain of uneasiness about the junction of the upper lip with the right ala nasi. The cause of this was soon explained by the appearance of a fungous growth on the under side of the upper lip, which increased so rapidly as to protrude, and bled copiously. It was obvious that it would now be necessary to tie the opposite artery, and after a due consideration of the attendant dangers, this was also ligatured. As soon as the ligature was tightened, the patient complained of loss of sight of the corresponding eye; but in the course of half an hour the sight was restored; the patient recovered without any bad symptom. In less than a week from the last operation, the morbid growths had dropped off.—*American Journal of Medical Science*, May, 1848.

CANCER OF THE UPPER LIP, AND IN THE FEMALE.

Sir Astley Cooper states that in upwards of two hundred cases of cancer of the lip, the upper lip was affected in only one instance; and he had never seen it in the female. Mr. Dickin, in noticing this observation, states that he has recently seen an instance of each of these rare exceptions. Both cases were women, and in one the cancer was in the upper lip.—*Medical Gazette*, July 7th.

CAUTERIZATION OF ADHERENT OMENTUM IN STRANGULATED HERNIA.

M. Bonnet, of Lyons, alludes to cases of operation for strangulated hernia, in which he sometimes finds pieces of omentum adhering so intimately to the sac, that it is impossible to reduce them. These cases are very embarrassing. If the omentum is left there is a risk of sphacelus and absorption of deleterious matters into the blood; if the portion be removed after being ligatured, the danger is scarcely less. Under these circumstances M. Bonnet advises that the irreducible portion should be destroyed by cauterization with the chloride of zinc, and relates two cases in which the practice was successful.—*Bulletin de Thérapeutique*.

OBTURATOR HERNIA, WITH SYMPTOMS OF INTESTINAL OBSTRUCTION WITHIN THE ABDOMEN.

Miss ———, aged 36, in September 1847, had some severe pain and local tenderness on pressure on the right side of the abdomen, above Poupart's ligament, with continued constipation and some vomiting. During several days these symptoms were relieved by the local application of leeches and fomentations, and the use of aperients and purgative injections. From that time she continued in her usual health until January 20th, 1848, when she was suddenly seized with symptoms of strangulated hernia, but no hernia could be detected, although she was repeatedly examined in reference to that point. Various means were employed, without any permanent relief to the symptoms of strangulated intestine. These means were continued during eleven days, when, in consultation with Dr. Fox and Mr. Blackmore, of Old Street Road, in whose practice this case occurred, it was resolved to recommend the patient to submit to an operation, the whole importance of which was fully explained to her. On the twelfth day from the first symptoms of strangulated intestine, Mr. Hilton opened the abdomen by cutting in the median line below the umbilicus, and ascertained the existence of an obturator hernia, which had not been at all suspected to exist. The intestine was withdrawn from the obturator opening by laying hold of it within the abdomen: no external tumour could be at that time detected in the upper part of the thigh. The operation was performed (with the patient under the influence of chloroform,) in the morning, and the patient died in the evening of the same day. The *post-mortem* examination gave evidence of extensive recent peritonitis. The portion of intestine which had been in the hernial sac was distinctly seen, and on examination was found to have been in a condition favourable to recovery. The hernial sac remained fixed in the thigh; the parts surrounding it were dissected; and a drawing is annexed to the record of the case, showing the position of the hernia.—*Medical Gazette*, July 21st.

OPERATION FOR STRANGULATED HERNIA IN AN INFANT SEVENTEEN DAYS OLD.

Mr. Fergusson related the following case to the Medico-Chirurgical Society:—

An infant, seventeen days old, had been perfectly well until the evening of Nov. 6, 1846, when it became fretful, and its sufferings appeared to increase rapidly. The symptoms were those of strangulated hernia, viz., a painful swelling in the region of the left inguinal canal, swelling and tenderness in the abdomen, constipation, and frequent vomiting.

The taxis having been applied without benefit, Mr. Fergusson proceeded at once to operate. An incision about two inches in length was made along the most prominent part of the tumour, passing obliquely from opposite the opening in the fascia transversalis, to within half an inch of the lower part of the scrotum, when the skin and subjacent cellular tissue were divided; a firm membrane of a dark blue colour, which was considered to be the hernial sac, was discovered, and cautiously opened. About a teaspoonful of turbid serous matter escaped, and on enlarging the aperture, a portion of small intestine was immediately exposed. The opening was now enlarged and the testicle was observed of a dark colour, partially covered by the gut. The stricture was divided in the usual manner, and the gut returned. The patient soon after went to sleep, and in the course of three hours there was a copious motion.

The above case is unique as regards the age of the patient. The age of the youngest subject, previous to the present, operated upon for strangulated hernia, being seven weeks. Several cases are on record of seven months, fourteen months, and sixteen months.—*Dublin Quarterly Journal of Medical Science*, May, 1848.

NEW REMEDY FOR TOOTHACH, THE PRINCIPAL AGENT BEING CHLOROFORM.

Mr. James Beatson, of Airdrie, says,—"Gum copal, when dissolved in chloroform, forms an excellent compound for stuffing the holes of decayed teeth. I have used it very frequently within the last two weeks, and the benefit which my patients have derived from it has been truly astonishing. The application is simple and easy. I clean out the hole, and moisten a little cotton with the solution; I introduce this into the decayed part, and in every instance the relief has been almost instantaneous. The chloroform removes the pain, and the gum copal resists the action of the saliva, and, as the application is so agreeable, those who may labour under this dreadful malady would do well to make a trial of it."—*Medical Times.*

MIDWIFERY.

HÆMORRHAGE FROM THE UMBILICAL CORD.

An useful hint is contained in the case reported below.

Mr. Hill was called upon to see an infant, eight days old, from whose navel there had been bleeding for five hours. Several applications had been employed without effect. The child appeared considerably sunk by the discharge; the cord was thick, and vessels apparently large. He first put a small compress on the part, which was retained by the pressure of the finger. He mixed up two tablespoonsful of plaster of Paris in a cup with water into a thick paste, and hastily removing the compress, he let the contents of the cup flow out on the part, where it immediately settled and hardened. He remained with the child some hours, and kept the abdomen partially exposed to the air: a few cracks having taken place in the plaster, he filled them up with fresh. He then put a bandage on the infant, removing it occasionally, and filling up the cracks that took place for the purpose of keeping the plaster solid, which was repeated for four days. It was then removed, and the bleeding did not return. On examining the cast there appeared three small papillæ, which the author supposes corresponded to the two arteries and vein which they occupied until the vessels became impervious.

Mr. Hill claims no merit of originality for this practice; he took the hint from Dr. Churchill, who, in a very excellent paper on the umbilical cord, published in the 50th volume of the *Edinburgh Medical and Surgical Journal*, page 302, for the year 1838, has suggested such treatment. The practitioner in this case, who was a pharmacien, had put a large piece of old linen about the cord after dividing it, and being saturated with blood it became hard, and threatened erysipelatous inflammation on the surface, to avoid which, he pulled away the cloth and remains of the cord before the process of separation had begun or the vessels became impervious. The plaster is worth a trial in such cases before more active means are adopted; it has to recommend it simplicity and being void of danger.—*Dublin Medical Press*, June 7, 1848.

TOXICOLOGY.

POISONING BY BELLADONNA.

Dr. Burton narrates the case of the porter to an hospital, who, by mistake, swallowed half an ounce of an aqueous solution of extract of belladonna. He did not immediately discover his error, but in five minutes experienced heat and dryness of the throat, succeeded by vertigo. Being alarmed, he drank warm water and vomited, but while in the act of drinking became powerless, and in a few minutes delirious and insensible. The stomach-pump was applied and some of the poison ejected, and he was then sent to St. Thomas's Hospital. When first seen by Dr. Burton, the patient was unconscious; face flushed; pupils widely dilated; and the retina totally insensible. The upper lids were prolapsed as in ptosis. The breathing was stertorous, and there were numerous rales. Heart's action feeble; pulse 116.

Treatment induced an amendment in the fulness and puffiness of the face, and consciousness returned, but the amendment did not continue, and he relapsed into stupor, followed by delirium, requiring restraint. This subsided, and he was found decidedly better next morning at eight a.m. After his recovery of consciousness, he complained of numbness extending over all parts of the trunk and extremities. The treatment adopted consisted of leeches and cold applications to the head, and the alternate exhibition of coffee and aromatic spirits of ammonia; the bowels were moved with croton oil, and the urine was drawn off.—*Medical Gazette*, June 16th.

ON THE SPEEDY INTERMENT OF PERSONS DYING FROM CHOLERA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

From the probability which exists of our being re-visited by cholera, I am anxious to call the attention of the profession to the subject of this letter,—viz., *the speedy interment* of the *real* or *supposed victims* of the disease,—a subject at once interesting in a scientific, and important in a humane point of view. Having acted on the occasion of the last epidemic as medical officer to two Boards of Health, it may be right to state that the opinions now to be expressed were then entertained, and this *Whitehall regulation* was then questioned and opposed by me; and further, that subsequent reflection has served to convince me both of the inutility and inhumanity of such regulation.

The consideration of the cause and nature of death by cholera will suffice to show, that in such a case the most unequivocal evidence of *real death* should be present, previous to interment even being thought of, much less carried into effect. In corroboration of this opinion I would ask, is there any, and if there be such, what is to be held as such unquestionable sign of death? On the answer to this question my justification for mooting the subject must and does depend; I therefore affirm that, there is but one absolute proof of death,—*i.e.*, the decomposition which follows it. If this be true, and it will hardly be denied that it is so, it follows that the interment of the body in *any case* previous to such change being apparent, is alike opposed to science, and a violation of humanity and its laws. Again, it may be asked, how long may *life be suspended?* I am not aware that any direct or satisfactory answer can be rendered to this query, and must, therefore, reiterate my assertion that the speedy interment of cholera-patients is wholly unjustifiable.

It was, undoubtedly, adopted with the view of protecting the living against infection, or contagion, which yet remains *sub judice*, so far as cholera is concerned, the great mass of evidence, at the same time, tending to the belief that cholera is not *essentially* a contagious or infectious disease. From my letters on the disease having been published in the Journal in 1832 and 1833, I will not at present occupy more of your space than is necessary to record my *protest* against a practice opposed to, and unsupported by, science, and repugnant to the best feelings of our nature,—affection, and veneration for the dead.

I am, Sir,
Your obedient servant,
GEORGE FIFE, M.D.

Newcastle-upon-Tyne,
Sept. 9, 1848.

Medical Intelligence.

APPOINTMENTS.

P. Martin Duncan, Esq., M.B., has been appointed Physician to the Essex and Colchester Hospital, in the room of Dr. Chambers, resigned.

John Cash Neild, Esq., has been elected Surgeon to the Bristol General Hospital, in the room of J. G. Wilson, Esq., resigned.

William Bird Herapath, Esq., M.B., M.R.C.S., has been elected Honorary Surgeon to St. Peter's Hospital, Bristol, in the room of Dr. Staples, resigned.

Charles Hall Clarke, M.D., has been elected Physician to the Bath United Hospital, in the room of Dr. Cardew, resigned.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, August 24th:—William Player, Swansea; William Richard Hilton, Whitehaven.

Thursday, August 31st:—W. Wightman, Swinefleet, near Goole; Walter William Miller, Eye; John Baker Boley, Bristol; William Gillett Cory, Brighton.

OBITUARY.

Lately, at Orthez, in the South of France, in his 104th year, Dr. Dufour, having preserved his faculties to the last.

BOOKS RECEIVED.

Proceedings of the State Medical Convention, held in Lancaster, April, 1848, and Constitution of the Medical Society of the State of Pennsylvania then adopted. Lancaster, U.S. Penn. 1848. 8vo. pp. 20.

On the Employment of Chloroform in Dental Surgery, its Mode of Exhibition, &c. By Francis Brodie Imlach, Dentist, Licentiate of the College of Surgeons, and Member of the Medico-Chirurgical Society of Edinburgh. Edinburgh: Sutherland and Knox. London: Simpkin, Marshall, and Co. 1848. 8vo. pp. 9.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen whose subscriptions are in arrear are requested to bear in mind the addition to the 23rd Rule of the Association, unanimously agreed to at the late Anniversary Meeting:—

"If any Member's subscription remain unpaid twelve months after it shall have become due, the *Medical Journal* and other publications of the Society shall be withheld from such Member till his arrears be paid."

R. J. N. STREETEN, Secretary.

TO CORRESPONDENTS.

Communications have been received from Dr. W. B. Herapath; the Birmingham Pathological Society; Dr. Fife; Mr. W. S. Cox; Dr. Paxton; Mr. J. Gabb; Dr. Cowan.

Lynn Hospital:—We have received the report of cases treated at the West Norfolk and Lynn Hospital, and hope that whenever Mr. Cotton's convenience will permit we shall be favoured with a continuance of these valuable reports.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

MEMOIR ON TURNING,

AS AN ALTERNATIVE FOR CRANIOTOMY AND THE LONG FORCEPS, IN DEFORMITY OF THE BRIM OF THE PELVIS, &c. &c.*

By J. Y. Simpson, M.D.,
Professor of Midwifery in the University of Edinburgh.

Section VIII.—Supposed Objections to the Practice in relation to the Life of the Mother.

In the last section, when treating of the effect upon the infant, of the practice which I propose in distortions of the pelvis, I took occasion to state, that the only proper test or measure of value between a novel operative measure like this, and those operative measures for which it was suggested as a substitute, consists in ascertaining, not the absolute mortality attendant upon the new operation alone, but the comparative mortality attendant upon the new as compared with the other and older forms of treatment. In the same way, in the present section, the question is not,—what is the absolute maternal mortality attendant upon delivery by turning in cases of contracted pelvis? but, what is the mortality attendant upon that operation, as compared with the mortality accompanying the alternative operations of delivery by the long forceps and by craniotomy?

In the records of midwifery, there do not yet exist, as far as I am aware, any data by which it is possible to compute either the general or relative mortality to the mother, from the use of the long forceps. Nor can we obtain any satisfactory approximation to the probable results of their employment upon the mother, by studying the maternal mortality attendant upon the use of the short forceps. For the short forceps are employed only in cases in which the head is already sunk down into the pelvic cavity, and when the application of the instrument is far less difficult, and its effects less dangerous, than when the long forceps are had recourse to in consequence of the child's head being arrested high up in the passages, from the obstruction of a distorted pelvic brim.

It is principally, however, as an alternative for craniotomy that we have to consider the propriety of turning; and there exist numerous data by which we may compare the relative mortality of these two operations. On this and other points in the statistics of midwifery, the laborious and valuable investigations of Dr. Churchill have thrown much light. The following table, which I have drawn up from Dr. Churchill's collection of data, shews us the general relative mortality attendant upon craniotomy and turning, in as far as regards the life of the mother.

Table VIII.

Shewing the Results to the Mother in Craniotomy and Turning.

Operation.	*Number of Cases collected*	*Number of Mothers lost.*	*Proportion of Mothers lost.*
Craniotomy	251	52	1 in 5
Turning ..	169	11	1 in 15

In some of these cases of turning, the deaths may, as Dr. Churchill points out, have been owing to the cause which demanded the operation, (such as placenta prævia,) and not owing to the operation itself; but, I believe with him, that the resulting calculation is "not very far from the truth."*

So far, such an imperfect estimate of the mere mortality of the two operations gives a result highly in favour of turning. But there is another element which comes into action, and which is not included in the above comparison. Most of the turning cases were instances in which the operation was performed in consequence of the child presenting transversely, and with most of them, comparatively little or no difficulty was probably encountered in getting the head to pass the pelvic brim. In the class of cases in which it is my object to recommend turning,—viz., with the brim narrow and distorted, would the operation, from its requiring the forcible extraction and compression of the head, be attended with much increase of peril to the mother?

On such a question being first suggested, most accoucheurs, I believe, would be inclined, *a priori*, to argue that the compression, however transitory, of the soft tissues included in the maternal pelvis, between

* Continued from page 398.

* Principles of the Practice of Midwifery, p. 245.

the interior of the maternal pelvic bones and the solid though elastic head of the infant, would be sure to be attended with inevitable danger, and evil consequences to the maternal structures; that the practice would, in short, be, as Dr. Radford has expressed it, "incompatible with the safety of the mother."

Prejudgments, however, even in pathological and practical matters of this description, are often wrong. Let us lay aside argument for experience, and supposition for fact, and examine, quietly and without prejudice, the actual and probable results of forced operative extraction of the infant's head, in cases of obstruction of the pelvic brim.

Dr. Denman had evidently some experience of the forcible extraction of the infant's head through contracted pelves, in preternatural presentations of the child. The rules of treatment, which I have already quoted from his chapter "On the Complication of Breech Cases with Distortion of the Pelvis," shew how entirely, or almost entirely, he trusted in these instances to the forced extraction of the head; and how very rarely, if ever, he had occasion to assist the delivery by craniotomy. And he states the results of all his observations in these instances, in terms most significant of its safety. "Nor have I *ever* known (says he,) any ill consequences follow the compression, which the soft parts of the mother undergo, between the head of the child and the sides of the pelvis, if proper attention were paid to the state of the bladder and rectum."*

The cases I have cited from Dr. Denman, and the others adduced in the preceding sections, so far afford corroborative evidence of this important remark. Altogether I have already referred to twelve or thirteen cases, in which the force of extraction or expulsion was so great that the head was not only compressed but indented. In none of these does the mother seem to have suffered from the compression or contusion. But these cases, it may be argued, are too few to entitle us to speak over-positively on the point. Let us turn, then, to others.

It often enough happens, among cases of pelvic distortion, that when the head of the child presents, and becomes obstructed at the brim, the mere perforation of the head, or first part of the operation of craniotomy, is not adequate to allow the operator to overcome, with subsequent ease, all the resistance of the obstacle opposing delivery. In many cases the second or succeeding part of the operation of craniotomy,—viz., the extraction of the head with the crotchet, through the contracted and obstructing brim, is still attended with difficulty, and requires for its completion more or less prolonged exertion by pulling and force. Under such circumstances, and though the child presents by the head and not by the feet, we have exactly the same form of danger threatening the soft structures of the maternal pelvis, as if the excessive traction were made, not in craniotomy, but in turning. The two cases agree in this one common condition, that in both an exertion of traction and force is required to pull the obstructed head through the contracted pelvic brim; and in both the soft tissues lining the pelvis of the mother are equally liable to be contused and compressed, under this traction and force.

Now, in cases of craniotomy, such as I here allude to, and which require the operator to use *great exertions*, in dragging the head with the crotchet through the obstructing brim, is the mortality to the mother much increased above what it is in the common run of craniotomy cases? Or, to state the question in other terms, are such cases of craniotomy decidedly more dangerous and fatal than other cases of the same operation, in which such excess of traction is not required?

Dr. Lee's "Clinical Midwifery presents us with a series of data relative to craniotomy operations, that may enable us to arrive at some accuracy of information regarding this question. In the first and second reports of his work, Dr. Lee details eighty-seven cases of craniotomy. The table No. IX. (see pp. 535—538,) gives a condensed view of the principal facts and results connected with these eighty-seven cases.

In most of the eighty-seven cases in the table, the operation of embryulcio was performed while the volume of the head was still above the brim. In the detail of many of the cases, Dr. Lee mentions whether the operation of extraction, after the skull was opened, was difficult or not; in thirty, however, of the eighty-seven, he particularly notes the extraction of the perforated head with the crotchet, as having been attended with difficulty and force. The foot-note (below)* contains a list of these thirty cases, and Dr. Lee's

* Practice of Midwifery, 1816, p. 499.

* *Case* 5.—"After perforation, great difficulty was experienced in extracting the head with the crotchet." *Case* 8.—"From the long-continued efforts required to drag the head into the cavity of the pelvis, it was evident that the delivery could have been accomplished in no other way, with safety to the mother." *Case* 9.—"After perforation, strong efforts were required to complete the delivery, and she died within forty-eight hours." *Case* 16.—"The force afterwards required to extract the head with the crotchet, made us regret that we had not interfered sooner." *Case* 29.—"After perforation, the head was extracted with difficulty by the craniotomy forceps." *Case* 31.—"The head was perforated, and the force afterwards required to extract it with the craniotomy forceps was so great, that I regretted having endeavoured to deliver before lessening the volume of the head." *Case* 32.—After perforation, so much force was required to draw the head through the pelvis with the craniotomy forceps, that I regretted having attempted to save the child." *Case* 34.—"The extraction of the head with the crotchet was a tedious and difficult operation." *Case* 35.—"I did not succeed without much difficulty in delivering with the craniotomy forceps." *Case* 38.—"I opened the head, and had much difficulty afterwards in drawing it down with the crotchet." *Case* 39.—"Perforation and extraction difficult." *Case* 40.—"Extraction difficult." *Case* 56.—"Extraction with the crotchet tedious and difficult." *Case* 59.—"Extraction difficult." *Case* 66.—"Great force required to extract." *Case* 76.—"The bones of the cranium were all torn away with the crotchet, before succeeded in drawing the base of the skull through the brim of the pelvis. * * Great force was afterwards

TABLE IX.—*Eighty-Seven Cases of Craniotomy, recorded by Dr. Lee, in the First and Second Reports of his "Clinical Midwifery."*

No. of Case.	No. in Report.	Cause of Obstruction and Delay.	No. of Pregnancy.	Length of Labour before Operating.	Difficulty or not in Extraction.	Death or Recovery of Mother.	Other Results. Inflammation, Sloughing, &c.	Remarks.
1	1	Rigid os uteri; vagina swollen and tender ..	1	Three days and nights	Not stated	Recovery	Sloughing; fistula	Long forceps tried first.
2	2	Head never through brim—convulsions	1	Fifty hours	Not stated	Recovery	Violent inflamm. of uterus	Long forceps tried first.
3	4	Head jammed in brim	—	Above 48 hours	Required 1½ hrs. bones of head &c. much torn	Recovery	Post-partum hæmorrhage	Tried first to apply forceps.
4	5	Head not passed brim. Os uteri half dilated	2	Two days (48 hours)	Great difficulty	Recovery	Slight uterine inflammation	Tried first to apply forceps; craniotomy in former labour.
5	8	Head not passed brim	1	Nearly 60 hours	Long contd. efforts	Recovery	.....	Recovered rapidly.
6	8	Scalp tumid; bones riding	2	Strong, above 30 hrs.	Little difficulty	Recovery		
7	8	Head wedged in brim	3	.....	Not stated	Death	.....	Ergot and repeated efforts with forceps tried previously.
8	9	Impacted in brim	—	.....	Strong efforts ..	Death	.....	Forceps tried first; vagina enormously swollen.
9	16	Not through brim. Os uteri rigid, not fully dilated.	1	About 50 hours	Force required	Recovery	.....	Not able to apply the forceps. No bad consequences followed.
10	17	Head low but not through the pelvis; anterior lip of uterus locked; labia swollen	1	About 48 hours	Not, except in overcoming perineum	Recovery	Inflammation and sloughing of vagina, & cicatrix	
11	25	Head and arm jammed in brim	2	Above 30 hours	.....	Recovery	.....	Delivered of first child by forceps.
12	29	The greater part of the head had passed through the brim	—	Forty-six hours	With difficulty	Recovery	No bad effect	Forceps tried first.
13	30	Great part of the head still above brim ..	1	Above 20 hours	Not stated	Recovery	Perineum torn by shoulders of infant	Forceps tried first; delivered since without assistance.
14	31	Head not completely in the cavity of pelvis	—	.....	Great force ..	Recovery	.....	Forceps tried first. A face presentation.
15	32	Head so low that the ear could be felt	1	Above 72 hours	Great force ..	Recovery	.....	Forceps tried first.
16	34	Head sufficiently low for the forceps	1	So long that she was quite exhausted	Tedious & difficult	Not stated	.....	Forceps tried first.
17	35	Head filled the cavity of the pelvis	1	Above 41 hours	Not without much difficulty	Recovery	.....	Forceps tried first.
18	38	Cavity of the pelvis occupied by a tumour the size of a cricket ball or larger	—	Twenty-four hours	Much difficulty	Recovery	.....	Forceps tried first. Next child delivered naturally at full period.
19	39	Os uteri not fully dilated, thick and rigid, and pressed down with the head through the brim of the pelvis	1	Above 50 hours	Difficult	Not stated	.....	Not able to apply the forceps.
20	40	Head firmly impacted in brim of the pelvis	1	Above 30 hours	Difficult	Recovery	Retention of urine; violent inflammation of vagina; fever	

No. of Case.	No. in Report.	Cause of Obstruction and Delay.	No. of Pregnancy.	Length of Labour before Operation.	Difficulty or not in Extraction.	Death or Recovery of Mother.	Other Results. Inflammation, Sloughing, &c.	Remarks.
21	41	Distortion of pelvis, and hard cicatrix of vagina	—	.....	Not stated ..	Recovery		
22	42	Head jammed in the brim	1	Long in labour	Not stated ..	Recovery	.....	Not able to apply the forceps.
23	43	Head within reach of forceps	1	.....	Not stated ..	Death	.....	Convulsions. Forceps tried first.
24	56	Pelvis distorted	1	Sixty-seven hours	Tedious & difficult	Recovery	Slight uterine inflammatn.	
25	57	Face presentation	—	Above 48 hours	Not stated ..	Recovery	Hæmorrhage	Face presentation.
26	58	Head and arm	1	Seventy-two hours	Not stated ..	Recovery	Severe inflamn. of uterus	Many efforts made at turning.
27	59	Head long fixed in the brim	3	Forty-hours	Difficult	Recovery		
28	60	Head many hours impacted in the brim; vagina swollen and tender	1	Thirty-six hours	Not difficult ..	Recovery		
29	61	Head in the pelvis, and an ear felt	—	Twenty-four hours	Not stated ..	Recovery	.....	Vectis and forceps tried first.
30	62	Os uteri rigid and partially dilated. Head compressed in the brim	1	Seventy-two hours	Not stated ..	Death	Great inflamn. and sloughing	
31	63	Head fixed in the brim	1	Above 24 hours	Not stated ..	Recovery		
32	64	Head of child passed into the pelvis. Labia swollen to the size of a child's head	—	First stage very protracted	Not stated ..	Death	Gangrene of vagina and external parts	
33	65	Great distortion of the pelvis	1	Thirty-six hours	Not stated ..	Recovery		
34	66	Head fixed in the brim; pelvis small	1	Forty-eight hours ..	Great force ..	Recovery	.....	Not able to apply the forceps.
35	67	Head above the brim	1	Great protraction, (above 24 hours)	Not stated ..	Recovery		
36	68	Small pelvis; os uteri rigid	1	Forty-six hours	Not stated ..	Recovery		
37	69	Great swelling of soft parts	1	About 72 hours	Not stated ..	Recovery	.....	First tried forceps. Twins.
38	70	.....	—	.....	Not stated ..	Recovery	.....	Violent puerperal convulsions.
39	71	Os uteri half dilated	—	Twenty-four hours	Not stated ..	Recovery	.....	Placenta prævia.
40	72	.....	—	.....	Not stated ..	Recovery	.....	Puerperal convulsions.
41	73	.....	2	Above twelve hours	Without much difficulty	Death	.....	Rupture of uterus.
42	74	Distortion of pelvis	—	After great protraction	Not stated ..	Recovery		
43	75	Head half through brim	1	Above thirty hours	Not stated ..	Recovery	.....	Retained placenta.
44	76	Distortion of pelvis; head not in cavity of pelvis	1	About 72 hours	Great force ..	Recovery	.....	Soft parts must have been severely contused.
45	77	Head scarcely entered the brim	—	About 48 hours	Difficult	Recovery	Uterine inflammation ..	Delivered by craniotomy before.
46	78	Head firmly compressed between sacrum and pubes	—	Forty-eight hours ..	Great force ..	Recovery	....	Right parietal bone of the child depressed and fractured.
47	79	Distortion of pelvis; head in the brim	2	Above 48 hours	Not stated ..	Recovery	.....	First child delivered by craniotomy.
48	80	Distortion of pelvis; head above the brim	1	Thirty-six hours ..	Slowly	Recovery	.....	The operation lasted two hours, and the bones of the skull were all torn to pieces before the head could be extracted.
49	81	Distortion of pelvis, greater part of head still above brim	1	Above 48 hours	Difficulty	Recovery	.....	Next child delivered without aid. The breech presented.

50	82	Head firmly jammed in the pelvis	3	Above fifteen hours	Easily	Recovery	.....	Convulsions occurred.
51	83	Head fixed in the brim	4	Above six days	Readily	Recovery		
52	84	Head firmly fixed in the brim	10	About 24 hours	Difficulty	Recovery	Retention of urine, sloughing of vagina; vesico-vaginal fistula	
53	85	.....	—	About thirty hours	Easily	Recovery	Sloughing; vesico-vaginal fistula	
54	86	Contraction of pelvis	—	.....	Extreme difficulty	Recovery	.....	A dwarf. The operation lasted nearly five hours, and the head of the fœtus could not be drawn through the brim of the pelvis, until the bones of the base of the skull were all torn to pieces.
55	87	Distorted by rickets; head above the brim	1	Nearly sixty hours	Delivered by turning	Recovery	Uterine inflammation ..	Turning resorted to in consequence of an arm having been brought down by the crotchet.
56	88	Head firmly impacted in the pelvis	—	Forty-eight hours ..	Great force ..	Recovery		
57	89	Head so low in pelvis that an ear was felt; closely surrounded by the inflamed vagina	—	Seventy-two hours ..	Some difficulty	Recovery	Retention of urine; violent inflammation and sloughing; cicatrix left in vagina	
58	90	Head at the external parts	1	Seventy-two hours ..	Not stated	Recovery	Retention of urine; sloughing	The tumefaction of the labia and vagina was such that the blades of the forceps could not be introduced.
59	91	Pelvis distorted; head in the brim	—	.....	Not stated	Recovery	.....	An unsuccessful effort had been made to deliver with the forceps.
60	92	Part of the head above the brim; os uteri partially dilated	1	Very protracted	Not stated	Recovery	....	Delirium for nearly a day.
61	93	Head wedged in the brim	—	Very tedious	Not stated	Death	Inflammation of bladder	
62	94	Greater part of head above the brim	1	Fifty hours	Not stated	Recovery		
63	95	Head squeezed in the brim	—	Forty-eight hours ..	Not stated	Recovery		
64	96	Head firmly impacted in the brim	1	Seventy-two hours	.....	Recovery	Sloughing; vesico-vaginal fistula	
65	97	Head jammed in brim; distortion of pelvis	—	.....	Not stated	Recovery	.....	Face presentation. Bursting of a thrombus of the vulva.
66	98	Head far advanced into the pelvis; vagina swollen	1	Fifty-three hours ..	Not stated	Recovery		
67	99	Head compressed in brim; os uteri partially dilated	1	Seventy-two hours	Not stated	Recovery		
68	100	Head has scarcely entered the brim; os uteri rigid and not half dilated	1	Thirty-eight hours ..	Not stated	Recovery		
69	101	Head deep in the pelvis, great swelling of the vagina, &c., ...	—	Thirty-seven hours	Tedious	Recovery		
70	102	Os uteri partially dilated; head above brim	1	Forty hours	Great force ..	Recovery		

No. of Case.	No. in Report.	Cause of Obstruction and Delay.	No. of Pregnancy.	Length of Labour before Operation.	Difficulty or not in Extraction.	Death or Recovery of Mother.	Other Results. Inflammation, Sloughing, &c.	Remarks.
71	103	Head and right arm presenting; os uteri half dilated	2	.....	Not stated	Recovery		
72	104	Head fixed in brim; vagina swollen and tender	—	About 72 hours	Not stated	Recovery		
73	105	Head strongly compressed in the brim; os uteri not fully dilated	—	Above 30 hours ..	Great force ..	Recovery		
74	106	Soft parts immensly swollen	—	Very protracted	Two hours required	Recovery	Retention of urine and sloughing of vagina	
75	107	Head firmly wedged in the brim; vagina swollen and tender	—	Above 78 hours	Great difficulty	Death	Uterine inflammation ..	Perineum slightly lacerated; retained placenta; slight hæmorrhage.
76	108	Head not passed brim	—	Forty-eight hours ..	Easy	Recovery		
77	109	Head impacted in the brim	1	Forty-one hours	Much force ..	Recovery		
78	111	Distortion of the pelvis; head compressed in the pelvis	—	Eighty-six hours ..	Not stated ..	Death		
79	112	Distortion of the pelvis; head not in brim	1	About 48 hours	Great force ..	Recovery		
80	113	Distortion of the pelvis; head above brim	—	Above 62 hours	Not stated ..	Recovery		
81	114	Head above the brim; os uteri not completely dilated	—	Above 78 hours	Not stated ..	Recovery	.....	There was a peculiar thickening at the upper and back part of the vagina, which seemed to arrest the progress of the head.
82	115	Greater part of the head above the brim ...	1	Above 53 hours ..	Force required	Recovery		
83	116	The head would not pass till perforated, being distended with fluid	—	.....	.....	Death	Inflammation of muscular coat of uterus	
84	117	Head above brim and distended with fluid	1	Nearly sixty hours	Easy	Death	Inflammation of uterus	
85	118	Head above brim and distended with fluid	1	Long in labour ..	Easy	Death	Disease of chest; inflammation of veins in pelvis	
86	119	Head distended with fluid	—	.....	Easy	Death	Rupture of uterus	Placenta prævia. Child turned first.
87	120	Head distended with fluid	—	Above 21 hours ..	Little difficulty	Death	Rupture of uterus	Child turned.

required to drag the shoulders into the cavity of the pelvis." *Case* 77.—"The operation of craniotomy was difficult." *Case* 78.—"Great force was required to extract the head after being opened." *Case* 81.—"The difficulty experienced in extracting the head with the crotchet after it was opened, proved that delivery could not have been completed by any other method." *Case* 84.—"After the head had been opened, two hours elapsed before I could extract it with the crotchet." "*Case* 86.—"The operation lasted nearly five hours, and the head of the fœtus could not be drawn through the brim of the pelvis, until the bones of the base of the skull were all torn to pieces with the crotchet." *Case* 88.—"After the perforation, so much force was required to extract the head, as to make it certain that the head could never have been extracted without its size being reduced." *Case* 89.—"I opened the head, and had some difficulty in extracting it." *Case* 102.—"Great force required to extract." *Case* 105.—"The head required great force to extract it after perforation." *Case* 106.—"Two hours required to extract the head with the craniotomy forceps." *Case* 107.—"Great difficulty in extracting the head." *Case* 109.—"So much force required to extract the head that it was obvious it never could have been delivered with the forceps, or expelled by the natural efforts." *Case* 112.—"The extraction required great force." *Case* 115.—"The force required to extract the head after perforation, rendered it obvious that the head could never have passed in the exhausted state in which she was."

own expressions with regard to the degree of difficulty met with in each case, in this, the second part of the operation,—viz., the extraction with the crotchet. In twenty-two of these thirty cases, it is stated that the head of the child was not through the brim at the time craniotomy was performed, but required to be pulled through it with the crotchet. In most of the remaining eight cases, the position of the head at the time of operating is not mentioned.

Out of the thirty cases presenting the subjoined degree of force and difficulty in the extraction of the head, two only of the mothers died. In the remaining fifty-seven cases, either the extraction is noted as easy, or was not so difficult as to have been considered worthy of being noted; and out of these fifty-seven cases, thirteen mothers died. The following arrangement expresses these results in a tabular form:—

TABLE X.

Table of Eighty-seven Craniotomy Cases, reported by Dr. Lee, shewing the Numbers in which Extraction with the Crotchet was—1, *noted as difficult; or,* 2, *not noted as difficult; and the results of these two Classes.*

Extraction of the Head after Perforation.	*Number of Cases.*	*Number of Deaths.*	*Proportion of Deaths.*
Noted as difficult ..	30	2	1 in 15
Not noted as such ..	57	13	1 in 4½

These interesting facts evidently point to one conclusion,—viz., that in distorted pelves, the amount of force required for the delivery and extraction of the head of the child, in cases of craniotomy, and hence, also in cases of turning, has far less influence upon the ultimate results and mortality of the operation than we could well have anticipated. But I anxiously desire not to be misunderstood on this point. I by no means wish to maintain, that the degree of force used in delivery has no influence upon the resulting degree of danger and mortality to the mother. Nothing could be more different from either my intentions or my convictions. But the above table shews that in the ordinary forms of distorted pelvis, the degree of force employed for effecting the transit of the head is far less an element of danger than could have been previously imagined; and the explanation of the apparent paradox is, I believe, two-fold. For, first, *temporary* compression applied to two special points in the circle of the pelvis, (as in the case when the child's head is dragged, by operative measures, through a brim contracted only in one diameter,) is by no means so dangerous, as more *prolonged*, though slighter degress of compression of the maternal structures, when the compression is equable, and diffused over the whole circle of the pelvic aperture, or the whole interior of the pelvic cavity, as in instances in which a hydrocephalic fœtal head is pressing like an hydraulic bag, equally, and on all sides. But, secondly, the effect of the law of the influence of force, is counteracted by, and subsidiary to, another law of a far higher degree of practical generalization,—viz., the law which I have illustrated at length in a preceding section, that "the danger attendant upon parturition, increases in a ratio progressive with the increased duration of the labour." And I have little doubt that if we had proper and adequate data for conducting the inquiry, it would be found that the safe result of those craniotomy cases in which force is employed in the delivery, is in a great measure owing to the *time* of the labour at which the delivery is accomplished; and that when the result is fatal, it is as much owing to the previous length or duration of the labour, as to the force employed. Dr. Collins, in his chapter on still-born children, details eight cases of craniotomy in which, after perforation, the extraction of the head with the crotchet required more or less severe exertion and force.* One of the eigbt patients died, but she

* These eight cases are the following:—1.—"No. 49, was 48 hours in labour of her first child. Having made no progress for the last 24 hours, the pulse becoming extremely quick, with great general debility, the head was lessened, and delivery effected by the crotchet. Considerable difficulty was experienced in getting the head through the pelvis in consequence of the hand having descended with it."—("Practical Treatise," p. 462.)—2. "No. 56, was a diminutive woman, much deformed; had been twice force-delivered in this Hospital, as from the size of the pelvis it was impossible for a child to pass entire; even after the bones of the head were completely broken down, much difficulty was experienced in completing the delivery."—3. "No. 209, was admitted, reported to have been four days in labour, and attended by a midwife; the uterus continued to act strongly, yet after waiting eleven hours the labour made no progress, and as there was no doubt the child was dead, the head was lessened. Many of the bones were removed before the delivery could be completed; the child was large and putrid."—4. "No. 210, after three days labour, the head, still at the brim of the pelvis, was lessened, and almost every bone removed before it could be delivered, and even after it was brought down, much exertion was required to free the shoulders and body. The child was large, and the abdomen somewhat distended with air. The mother seemed at this time almost lifeless, having lost the power of swallowing. The hand was introduced into the uterus, which was quite relaxed, the placenta was gently removed, and the patient expired immediately. On dissection, the uterus was found healthy, but badly contracted, containing a small quantity of coagulated blood; the intestines were in the highest state of congestion, and there was about a pint of fluid in the abdominal cavity, with portions of coagulable lymph in different parts, seemingly the effects of inflammation previous to labour. On opening the chest, the lungs were observed to adhere so firmly as to require the knife in many places to separate them. Nothing was discovered to account for the suddenness of death."—5. "No. 256, was 32 hours in labour previous to admission; her pulse was rapid, and tongue foul. She was delivered some hours after she came in, by lessening the head, which was greatly enlarged from hydrocephalus; there was some difficulty in completing the delivery, even after the bulk of the head had been as much as possible reduced."—6. "No. 303, was admitted reported to have been three days in labour of her first child; the head was low and firmly fixed in the pelvis; the bladder greatly distended with urine,

had been seventy-two hours in labour when the operation was undertaken; all the other seven recovered. In six out of these seven cases, craniotomy was adopted earlier; in one, before the labour had reached sixteen hours in length; in all, before it had passed forty-eight hours from its commencement.

The manner and extent in which the laws of danger attendant upon this and other particular obstetric operations, are controlled by, and absorbed in, the more general law of the attendant mortality, depending upon the length or duration of the labour, have been already illustrated, (see Section IV.,) in reference to delivery by the forceps, and delivery by the crotchet, taken individually. The law and its results, however, are so extremely important as bearing upon the question of the present section, that I will, in further confirmation of it, and at some risk of repetition, throw into a combined form and table, all the forceps and all the craniotomy cases mentioned by Dr. Collins, in which he specifies the duration of the labour. In other words, we will conjoin the two tables previously given in Section IV., into one; and examine how much the maternal mortality was modified in tedious and laborious labours, requiring instrumental aid, by the date of the labour at which that aid was given. Our former tables contained 24 cases delivered by the forceps, and 77 delivered by craniotomy; in all 101 instrumental labours. The results were as follows:—

TABLE XII.

Shewing the Results of 101 *Instrumental Deliveries in which the Duration of Labour at the time of the Operation was noted.*

Duration of Labour.	*Number of Cases.*	*Number of Deaths.*	*Proportion of Deaths.*
Under 24 hours	32	2	1 in 16 died.
From 25 to 48 hrs	42	6	1 in 7 died.
Above 48 hours	27	11	1 in 2½ died.
Total	101	19	1 in 5 died.

This combined table of Dr. Collins' instrumental deliveries, fully bears out the important conclusion regarding the influence of the antecedent duration of labour, that we have already seen to be derivable from the study of the two operative measures, the forceps and crotchet, taken singly and individually. The evidence of the present table, like the evidence of those previously given, (See Tables Nos. V. and VI.,)* amounts to this,—that the maternal mortality accompanying instrumental delivery, is regulated more by the period of the labour, at which the artificial interference is practised, than by the nature of the operation itself, or by any other contingent circumstance,—the general fatality being decreased in proportion as the operation is performed early, and increased in proportion as it is postponed and delayed longer and longer from the date of the first commencement of parturition. But, admitting that this holds true in regard to instrumental delivery by the forceps and craniotomy, it may be doubted and objected that it perhaps does not hold true in regard to artificial delivery by the operation we propose to employ,—viz., turning. Let us interrogate Dr. Collins' facts, in order to obtain an answer.

In his Report of the Dublin Lying-in Hospital, Dr. Collins gives the result of thirty-three cases, in which turning was practised in consequence of presentation of the shoulder or arm. In one of these cases the placenta presented, and I exclude it as thus containing a source of danger quite independent of the turning. Among the remaining thirty-two cases, there are two deaths, or one in sixteen; and twenty-four in which the date of the duration of the labour, at the time of turning, is stated as ascertainable. In only one of these twenty-four cases, is the labour noted as having exceeded thirty hours in length, and this protracted case was an instance of twins, in which the second child presented preternaturally, and required turning. In twenty-one of the cases the labour was terminated before twenty-four hours; among these one died,—a case complicated before delivery with severe accidental hæmorrhage; in three it was prolonged beyond twenty-four hours, and one of these three mothers died. When arranged in a tabular form, the results are as follows:—

having been retained for thirty hours; pulse 140; tongue dry and white. The catheter was passed and three pints of urine removed. As the abdomen was free from pain, it was thought advisable to watch the effect of uterine action for some time. After waiting five hours, during which the pains were pretty brisk at intervals, still the head made no advance; it was lessened and brought away with the crotchet. There was considerable exertion required to bring down the shoulders; the abdomen was much distended with air, the consequence of putrefaction. She died on the fourth day from delivery."—7. "No. 667, the labour lasted 30 hours; the head was firmly fixed in the pelvis, and had made no progress for twelve hours. As the heart's action had some time ceased, and the mother's pulse was 140, the head was lessened. Great exertion was necessary to effect delivery in consequence of the head being much ossified."—8. "No. 725, this patient, when admitted, was reported to have been 60 hours in labour; the os uteri was very little dilated, and the head high up in the pelvis. The pains continued constant for 24 hours after she came in, yet the labour made little progress; the mouth of the womb was rigid, jagged, and had the feel of cartilage. The child being dead, as indicated by the stethoscope, the head was lessened and left in that state for some hours, and afterwards cautiously brought down. Considerable force was necessary to complete the delivery, though the child was putrid."

* Journal for 1848, pp. 59 and 60.

TABLE XIII.

Shewing the Mortality accompanying Twenty-four Cases of Turning for presentation of the arm and shoulder, as regulated by the Previous Duration of Labour.

Previous Duration of Labour.	*Proportion of Deaths of Mothers.*
Below 24 hours	1 in 21 died
Above 24 hours	1 in 3 died

The data in the preceding table are not numerous, but still they will probably be allowed to be sufficient evidence of the fact, that the degree of maternal danger attendant upon turning, as upon other modes of operative delivery, is regulated and modified by the date of the labour at which the delivery is practised; artificial labours, like spontaneous labours, increasing in their mortality in proportion as the previous parturient action has been allowed to be increased and prolonged in its duration and length. Hence, also, necessarily follows the same deductions which I have already more than once adduced, viz.:—

1. A means of artificial delivery, such as turning, which, in cases of pelvic contraction, would enable us to finish the labour at an early date, should, as a general rule, add greatly to the safety and chance of life of the mother, as compared with a means of delivery such as the long forceps or craniotomy, which cannot be usually and legitimately practised till a much later period after the commencement of parturition.

2. The facts I have adduced in the present section shew, that the exertion of force in artificial delivery is attended with comparatively little danger, provided always the delivery is early; and that the employment of it is by no means so hazardous as the simple long continuance and protraction of the labour.

3. All these deductions are only corollaries to the higher and more comprehensive law, that the degree of danger and fatality attendant either upon natural or morbid parturition, increases in a ratio progressive with the increased duration of the labour.

(To be continued.)

CASE OF RHEUMATIC ENDOCARDITIS AND CHOREA, WITH OBSERVATIONS.

By JOHN GABB, M.R.C.S.E., and L.A.C., Bewdley.

James Griffin, aged 12 years, a tailor's apprentice, came home from Kidderminster ill, on Saturday, December 11th, 1847, having been poorly for two or three days previously, chiefly suffering from pains in his back and limbs, the ankles and knees being swollen and tender, declared to be suffering from rheumatism by a medical man who saw him at this time. After coming home he appeared to improve gradually till the following Thursday, when, in the evening, having been more cheerful than usual during the day, he first complained of a shooting pain, with twitches, up the right side of the neck, which symptoms were followed by involuntary movements of the head and right arm, rolling of the eyes, and an inability to speak for the space of about one hour; his power of utterance then, in a great measure, returned, but without the muscular movements being diminished. During the next two days he gradually became less and less distinct in his utterance, and then again lost all power of speech. At the same time the involuntary movements also increased, the left arm and the legs, in fact the whole muscular system, becoming affected, and up to the present date, December 26th, his mother says he has daily become worse and worse. He was now placed under my care. Since the jactitation commenced he has taken frequently-repeated doses of purgative medicine, which have operated freely upon his bowels, and two days ago his head was shaved, and a blister bound upon the scalp. After the blister had produced its effect, he obtained about two hours sleep, the first for several days and nights. Whilst asleep he was perfectly quiet.

At my first visit I found him lying upon his back, low down in the bed, generally and violently affected with involuntary movements; arms, legs, head, neck, face and eyes, the abdominal muscles, and the muscles of the back, all active, and without the least apparent operation of any directing influence. He was speechless, and unable to make any sign of consciousness, except by means of a low moaning noise, and this noise he constantly made whenever his mother left him for a short time by himself. He was only capable of swallowing a small quantity of fluid at a time, and that with extreme difficulty. The pupils of both eyes were somewhat dilated; the left eye slightly bloodshot. (On his left hand was situated a window, at a short distance from his bed, not very well glazed.) His countenance was pale, with a vacant expression; skin generally pale and cool; tongue slightly furred; pulse quick, with difficulty felt at the wrist, owing to the activity of the arms; heart beating with preternatural impulse; pulsations visible, shaking the surrounding parietes of the chest, and communicating to the hand the sensation of a vibratory thrill, without any apparent increase of dulness on percussion; pressure with the hand upon the region of the heart very perceptibly increasing the movements of every part of the body. The lungs everywhere imparting a healthy resonance on percussion; no unnatural enlargement or hardness about the abdomen; bowels inclined to costiveness; urine scanty and rather high coloured. No sleep since the night before last, the jactitation having apparently kept him awake, which also renders the stethoscope useless in the examination of the heart and lungs.

R. Vin. Ant. Tart., m. xx.; Sp. Æther. Nitr., m. xv.; Aquæ, cz. ss. Sit haust. quartis horis sumend. The following anodyne embrocation for the spine, was ordered to be used night and morning:—Tinct. Opii, Tinct. Belladonnæ, utrq., dr. ij.; Lin. Saponis Co., oz. iss.. A dose of Ol. Ricin., Ol. Terebinth. Rect., utrq., part. æq., to occasionally operate on the bowels.

January 6th, 1848. The same plan of treatment has been continued. In a few days after I first saw him he had become sufficiently quiet for me to make use of the stethoscope, and on examination of the heart, I found a murmur with each sound, loudest with the first, and heard most distinctly at the apex, corresponding to the thrill felt by the hand applied over the heart, but differing decidedly from the sound of friction, which, with the persistence of the signs before mentioned, although with diminished intensity, left no doubt of the existence still of some endocarditis; and therefore, although the surface of the body was pale, and beginning to have a shrunken appearance, and the feverishness had become scarcely perceptible, I ordered four leeches to the region of the heart, and a continuance of the same medicines. I, however, directed the embrocation to be omitted, as I had not observed any advantage from its employment. The night after I first saw him he obtained a little sleep, and his nights have gradually become better ever since, but this is attributed to the quieting influence of the tartarized antimony on the muscular movements, rather than to the anodyne embrocation. His mother tells me he had taken "sleeping powders" without sleep being produced, previous to his being placed under my care. Three leeches only were applied, but they lowered considerably the impulse of the heart, and diminished the frequency of the pulse at the wrist. He had remained much the same for a day or two before this application, but afterwards began again to improve rapidly. At present the jactitation is much less; he sleeps well at night; has no fever; pulse 80; impulse of the heart natural; a little vibration still felt by the hand, and a slight murmur still audible with each sound. He has not yet swallowed anything but fluids, nor has he been able to utter a single word. His countenance has become less vacant in expression, and he appears to be more attentive to surrounding objects, but his whole body has a pale and shrunken appearance.

R. Infusi Rosæ Co., oz. j.; Sp. Æther. Nitr., m. xxx. M. Sit haustus ter die sumendus. As nourishing a diet as he can take.

12th. Better. R. Ferri Sulph., gr. ij.; Infusi Rosæ Co., oz. j. Fiat haustus ter die sumendus.

31st. Since the 12th inst. his improvement has been very rapid; in the course of three or four days he spoke indistinctly, for the first time, and the next day could talk almost as well as ever; again in a day or two he could stand with his back against a wall, and the following day walked across the house without support. The muscles of the right arm and right side of the neck were now again only affected, as in the commencement of the attack of chorea; and at the present date he has not a symptom of the latter affection remaining. He has gained considerably in flesh and healthy appearance, but is still rather pale. Continue the medicine.

February 17th. All treatment discontinued; his natural intelligence and activity are quite recovered; he has become stout, with every appearance of health, but I find there still exists a slight murmur with the first sound of the heart, heard at the apex, the second sound being quite natural. On questioning him he says, the only difference he finds in his present and his former state is, that running gives him *a stitch* in his left side, which it had not used to do; in all other respects he thinks himself stronger than ever, and his mother considers him decidedly better than he had been for two or three years previous to this attack. He says he remembers everything that occurred in his presence during his illness, and of this has given some evidence, in repeating observations made in his room with regard to his management, &c. He also states, that for a few days at the commencement of his illness, he had a very severe pain in his head, which was very much relieved by the blister before I saw him; and that the embrocation, which was discontinued in consequence of no benefit being *perceived* to be derived from it, afforded him *great comfort* after each application, although he cannot say that it did so by relieving him of any particular pain; but, said he, "how it made me knock about while it was being rubbed in," and it was the increased activity manifested by the muscular system during this operation, which induced me to omit its employment. There is one circumstance in his previous history which I might, perhaps, mention, although, most probably, it will not be supposed to have had any influence upon his present attack,—viz., his being resuscitated from apparent death by drowning, in July, 1847, after considerable perseverance in appropriate means, when, for a day or two, he appeared to be rather dull and stupid, but then again became as well as usual, without feeling the least inconvenience from his accident.

Remarks.

The above case brought to my recollection a casual remark of an eminent metropolitan physician, to the effect, that he was surprised at so frequently meeting with evidence of structural disease of the valves of the heart in obstinate and incurable cases of chorea. Dr. Copland, Dr. Bright, and others, have observed a connection occasionally between rheumatic pericarditis and chorea; but I am not aware of any recorded cases of the latter affection in connection with endocarditis. If the observation with regard to the frequent occurrence of valvular disease, just referred to, be correct, may it not be inferred that endocarditis has frequently existed, without being detected, in association with recent attacks of chorea? I am the more inclined to entertain such an opinion from the fact, that until the signs were sought for in the above case, there was nothing at all to lead anybody to suppose they existed, and from the circumstance of their having been overlooked by a medical man before I became the attendant of the boy. My attention was directed to the condition of the heart and lungs in the first instance, to satisfy myself of the propriety of administering chloroform, (or æther and chloroform together, which I think *safer* than the latter alone, and at the same time equally efficacious,) but the evidence of valvular inflammation met with deterred me from its administration, and induced me to rely on the antiphlogistic and sedative influence of small repeated doses of potassio-tartrate of antimony, until the *proper period* should arrive for giving tonics, which,

if given at first, might have rendered the affection permanent, if not have led to a fatal result in such an aggravated case. But most probably in this case the endocarditis would have been discovered, whether I had thought of administering chloroform or not, as in all serious cases I make it a rule to ascertain the condition of the heart and lungs.

I have just seen two brief notices of the efficacy of tartar emetic in chorea, in the last Volume of "Braithwaite's Retrospect," by G. Corfe, Esq., of London, and M. Salgues, of Dijon. To their testimony I beg to add mine, and will conclude this communication, with expressing a hope, that by its being employed to subdue inflammation of the serous membranes of the heart, spinal cord, or brain, (which are, one or other, or collectively, probably always more or less implicated in this disease,) previously to the administration of tonics, fewer cases will be met with to prove incurable, and that such cases as have hitherto been curable, may be rendered still more so by the rational and simple plan of treatment, which I, trust the report of the above case may be sufficiently explicit to suggest to those members of the profession, who have not paid particular attention to this curious disease.

Bewdley, September 11, 1848.

ON THE

MEDICAL AND GENERAL TREATMENT OF LOCAL DISEASES IN PREFERENCE TO THEIR TREATMENT BY OPERATION.

By Thomas Hunt, Herne Bay.

I. Strangulated Hernia.*

Having shewn that the taxis, carefully and patiently applied, will generally succeed in reducing a strangulated hernia,—an opinion confirmed by the late Mr. Liston's observation, that. "if the surgeon conduct the proceeding with a *wish* and *determination*, if possible, to succeed, he will generally find his attempt, after a time, crowned with success,"† I proceed to the considerations of the objections to the operation, which are, in fact, far more serious, than seriously thought of by the generality of operators.

It must be well considered at the outset, that the question *now* under discussion, is not whether *every* hernia can be reduced by the taxis, but whether, in cases which cannot (with the utmost skill and patience,) be so reduced, the operation is likely to save the patient's life. I believe it so unlikely, that it is even questionable whether, in the most favourable cases, the risks of the operation do not *diminish* the already slender chance of recovery. In cases where the stricture is at the external ring, and the intestine is inflamed or tender from pressure, or actually giving way from the arrest of the circulation, it is evident that the introduction of an instrument between the stricture and the intestine, cannot be effected without sufficient force to destroy the structure of the bowel. When this is done, and the bowel returned, what is the value of the patient's life?

The statistics of the operations for hernia are appalling. Mr. Macilwain reports, that out of 500 cases taken at random, in which the operation had been performed, both in this country and on the continent, scarcely less than *one half* terminated fatally;* and of these fatal cases, perhaps more than one half might have been saved by the right use of the taxis. Hospital surgeons are generally called to cases in which the taxis has been neglected, or imperfectly tried, some of them roughly handled, or the protruded bowel even burst by the violence of the manipulations, and the evils of strangulation increased ten-fold by injudicious attempts at reduction. They therefore, one and all, advise that *no time should be lost*; that, if the taxis fails, especially under bleeding, the warm bath, relaxing enemata, &c., the operation should immediately be had recourse to. But, how many cases of strangulated hernia would be taken to hospitals at all, if every surgeon were better informed in the right use of the taxis? Probably not one hundredth of the number now recorded in the hospital books. The saving, therefore, of unfortunate patients suffering from strangulation, is in the hands of private surgeons, country surgeons especially. The hospital cases are, probably, more than half of them, hopeless cases, irreparable mischief having been done, or suffered, before their entrance into those asylums; and if reduction is there again attempted *in the prevailing method*, the subsequent operation affords but a sorry chance for the unhappy patient. The dangers of the operation, (I need not enumerate them, they are too well known,) added to the dangers of the accident, aggravated by the "pushing and kneading," and often augmented to a fatal degree by tobacco enemata and other depressing remedies, are at best so formidable, that it may well be questioned whether a case too far gone for reduction by a gentle but determined application of pressure to the tumour, may not as well be left to its hopeless and helpless fate. On this point, however, I will not insist. No reproach can rest on a surgeon who is induced to operate in such an emergency; but in more hopeful cases, in those, namely, where the chances for the success of the operation would be considered promising, the chances for the success of the taxis, skilfully and patiently employed, are, in my estimate, immeasurably greater; and I conclude by earnestly entreating that it may be *tested by experiment, and not by argument*. It is easy to *imagine* cases in which the taxis *must* fail, and I do not deny the existence of such cases, but I believe they are at once so rare, and so obscure in their diagnosis, that they cannot justify recourse to an operation which so very frequently fails to save the patient.

II. Retention of Urine.

If cases of strangulated hernia have been lost, as is generally believed, by delay in the operation, much more frequently have patients died from *retention of urine*, from culpable delay or blundering incompetency in passing the catheter. Yet, there are many cases of

* Continued from page 320.

† Liston's Practical Surgery.

* Lancet, 1845.

retention, simple in their nature and easily relieved by medical treatment, which from error in diagnosis have been aggravated to the imminent danger of the patient, by unnecessary and unsuccessful attempts to introduce an instrument into the urethra under circumstances of inflammation or spasm. These causes of retention are so frequent, that the elder Grainger was once heard to say that he had never met with a case of retention which he could not relieve by medicine. Few practitioners can go so far as this: yet, in my own practice, and in that of several medical friends with whom I have conversed, the cases of retention, requiring the catheter, have formed a very small proportion of the whole. I do not refer, of course, to cases of stricture, in which there is an evident mechanical obstruction, which must be removed by mechanical means, guided in some instances by all the resources of surgical skill; nor to cases of obviously enlarged prostate pressing mechanically on the urethra. I am thinking of those every-day cases, in which, without any apparent cause, a patient suddenly finds that he cannot micturate, and sends to the surgeon in great alarm. The use of the catheter in these cases, without any previous trial of other means of relief, is, I fear, too common a practice with young and inconsiderate practitioners, and as frequently leading to disastrous consequences, merits exposure and severe reprobation.

That the officious and indiscriminate use of the catheter in retention of urine, is not always a harmless error, will be better illustrated by the following case than by mere declamation:—

In the autumn of 1836, a neighbouring practitioner who was esteemed a skilful operator, requested me to try my hand at the introduction of a catheter in a case of extreme danger, in which, after many fruitless attempts on his part, alarming symptoms had appeared. I found a middle-aged man, with a distended bladder, and a copious infiltration of urine into the cellular tissue of the pubis, preputium, and scrotum, the two latter organs having already become extensively sphacelated. The whole of the scrotum, and the greater portion of the prepuce were perfectly black, cold, and insensible; but the pulse had considerable force. The patient had formerly been troubled with hernia, and the tumefied state of the inguinal region and scrotum was mistaken by the surgeon for a large hernial tumour; no suspicion having been entertained of the real nature of the case. I declined making any further attempt at catheterism, but advised that free incisions should be made into the tumefied cellular membrane, the skin being tense and crepitant. This was accordingly done, giving exit to a pint or more of urine, which flowed freely from each incision. A small vessel was accidentally wounded, from which lucky event the patient lost a considerable quantity of blood; the hæmorrhage yielded to slight pressure, and in half an hour or less, without any other means being used for his relief, the patient evacuated his bladder in a full stream from the urethra, to the extent of three or four pints of urine. Under subsequent *medical* treatment the sphacelated portions soon separated and sloughed away, and the patient recovered, not without deplorable mutilation. It is needless to add, that a few leeches to the perineum with saline aperients, in the first instance, would have reduced the local inflammation which had caused the retention, and thus rendered surgical treatment as unnecessary as it proved to be mischievous and destructive.

Retention of urine in the female very frequently occurs from causes which seldom affect the bladder of the male subject. After difficult labours, and in some cases of hysteria, the bladder loses its contractile power, and the catheter is required. The operation is so easy that it is scarcely possible to fail in the attempt, and there is generally no objection to its performance.

It has been observed, however, and very justly, that in hysterical girls, who complain of retention of urine, it is often better to leave the bladder to its own resources than to repeat the operation every time that viscus becomes slightly distended. Both the power and the *will* to retain the urine are mysteriously exerted in these cases; but both will yield to the urgent distress resulting from a firm refusal to catheterize the patient. Every practitioner is familiar with these cases, and I know of no absolute rule to determine our conduct.

CASES FROM PRIVATE PRACTICE.*

By John Richard Wardell, M.D., Edin.

Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

Case VIII.

Subclavian Aneurism.

"A spontaneous aneurism," says Mr. Guthrie, "is generally slow in its growth, not, perhaps, exceeding the size of an egg in a year, and rarely that of a flattened orange." In this example was a degree of enlargement far beyond that of which Mr. Guthrie considers to be the maximum ratio of increase. In January the impulse could be felt but one-third of the extent which it could eight or nine months afterwards. In the first admeasurement from the superior pulsatory margin, passing over the tumour downwards, to the inferior pulsatory margin, $4\frac{1}{8}$ inches; horizontally, $3\frac{5}{8}$ inches; but in September the same admeasurements had increased to $12\frac{1}{4}$ inches, and $10\frac{3}{8}$ inches. The pulsatory thrill would be communicated much farther than the parietes of the aneurism extended, for it is not probable that the tumour itself would enlarge to such dimensions. The effusion and organized matter in the subcutaneous cellular tissues was the reason why the impulsions could be distinctly felt so far as mentioned. The previously-named rules to be observed in diagnosis, enable us to decide the question, because the impulsion against the parietes, and the retracted impulsion, are only distinguishable when the aneurism itself is pressed upon. We know it

* Continued from page 519.

to be a law in acoustics, that sound and the vibrations of tumours are more transmissible through the medium of a solid, than a liquid, body; and thus we judge of the nature of morbid collections in the thoracic and abdominal cavities. Two or three weeks ago, when in the wards of one of the London hospitals, the visiting physician showed me a patient who had an obscure pectoral affection, and where it was very difficult to determine from what the circumscribed dulness proceeded. It was considered, and with the most probability, that the cause of this was a collection of some description of fluid, because the thrill given by the heart's action was inaudible. The sounds, on application of the stethoscope, were weak and distant, and that resistless sensation given to the fingers on percussion, indicated that a fluid, (not a solid body,) was present. In instances of hypertrophy of the heart, with large liver, the pulsations will be distinctly felt in the hypochondrio-epigastric region, dependent upon powerful and anormally-increased action of the heart being communicated through the diaphragm to the engorged hepatic viscus, and so distinctly are the pulsations transmitted, that in one case which I now well remember, two talented professors maintained very diverse opinions relative to the true nature of the disease; one contended for cardiac hypertrophy, with enlarged liver, the other for aneurism of the descending aorta.

In external aneurisms, there are differences, not only in the progress of morbid conditions of the tumour, but also in the manner in which the mortal results supervene. In the former they die gradually, by the incessant oozing of blood; in the latter, by laceration of the sac, when death momentarily ensues. The integumentary coverings of an external aneurism are too distensible to give way suddenly; as the tumour enlarges, greater pressure and distension are produced, the cutaneous and subcutaneous tissues become engorged and swollen from obstruction in the circulation. Thus inflammatory action is instituted, and at that particular part on the external surface of the tumour where there is the greatest degree of pressure, an ill-defined pointing is observed, and at the apex of this a slough is formed, on the giving way of which the blood slowly discharges, until a mortal syncope supervenes. Armstrong, it is seen, had this oozing for many hours before he sank. On reference to his case, it is stated that at one time the tumour was an irregular tri-nodulated swelling; before long one of the prominences became much larger than the others, and ultimately upon the point of it was found the fatal eschar. Internal aneurisms not having the tegumentary coverings, and thus wanting that support to the distended parietes, burst by laceration, and not by the formation of an eschar, as in Armstrong. The external coat is so put upon the stretch, that at length it divides, and death instantly ensues, as in the case of the patient in he North London Hospital, when the man died momentarily, and on the posterior surface of the aneurism, which I personally examined, was a rent in the wall of the sac. Mr. Hodgson, when speaking on this point, says, "When the sac points externally, it rarely or never bursts by laceration, but by the extreme distension causes the integuments and investing parts to slough, and upon the separation of the eschar the blood issues from the tumour."

The treatment of this alarming affection very importantly depends upon the locality of the disease, and the more distant an aneurism is situated from the centre of the circulation, the greater are our chances of effecting a cure. In cases where operative means can be had recourse to, there are great hopes of success, but where dependence is to be placed upon medicinal measures, such measures are almost invariably impotent—are a mere nullity. Occasional blood-letting, in small quantities, but so as to avoid the occurrence of reaction,—low non-stimulating diet,—abstaining from fermented liquors,—the avoidance of every cause of vascular excitement, whether of a mental or physical description,—such medicines as lower the action of the heart, may always, with propriety, be recommended. The only hope is in the knife, and where such is impossible, vain, nearly invariably, are all essays at the cure. Pressure has been recommended, and cases have been recorded where it has absolutely succeeded, yet when we consider that such pressure is only applicable in external aneurisms, and when so situated that there is a firm basis against which the pressure can be accurately applied, without injury to the subjacent parts, where the collateral branches are sufficient to carry on the circulation requisite for nutrition; and further, that the pressure treatment is apt to produce sloughing of the integuments, and is uncertain in the results, it thus, as a means of cure, does not merit much attention. Popliteal aneurisms are, perhaps, most eligible for this method, because the pressure can be accurately adopted, the vessel is distant from the heart, and the collateral branches are sufficient to nourish the limb.

With respect to the application of a ligature, in all cases of spontaneous aneurism the vessel should be secured at some distance from the tumour, because in such, the diseased condition of the arterial tunics extends generally both above and below the actual seat of enlargement; hence, if it is not taken up where the walls of the vessel are positively healthy, instead of the fibrinous plug being formed, and the canal being rendered impervious, ulceration takes place, and secondary hæmorrhage is the result. Some authorities have recommended the ligature to be applied on the distal instead of the cardiac side, but experience, and the opinion of more recent writers, have incontestably decided in favour of the latter. In a vessel of such large calibre, and so near the heart as this was, it would have been plausible to presume, had we not been

supplied with proofs confirmative of the point, that the application of a ligature would not be attended with the same felicitous results, as in others of the arterial trunks, and the reasons for supposing so, are,—1st, because the only place at which the ligature could have been applied, with any hopes of success, would have been at the innominate artery, which vessel it was highly probable was also diseased; and again, in four cases which I find where the innominate has been tied, all the patients died; 2ndly, because the innominate artery, (supposing it to be in a state of positive health,) by being so near the heart, might, by the inflammation which would necessarily be induced, extend that inflammation to the lining membrane of the heart, and thus institute a dangerous attack of endo-carditis; and again, the powerful impetus with which a large column of blood would be propelled into the remaining portion of the innominate canal would be such as to prevent the deposition of fibrinous matter; 3rdly, two such large canals as the carrotid and subclavian being cut off, would the anastomosing branches be sufficient to maintain with due nourishment, those parts which are, for a supply of blood, dependent upon those trunks?—and would not such an unequal stress being thrown upon the left side tend to engorgement in the left cerebral hemisphere? Duly weighing these conditions over, the improbabilities of cure founded on physiological and pathological reasoning, together with the results which *have* followed tying of the innominata, it was conclusive that the only recommendation to be given to the patient, (who was very desirous of an operation being performed,) was, to allow the disease to progress, and not run the imminent risk of having his life shortened still further by surgical interference. I may here mention in conclusion, that, not very long ago, M. Rossi tried the distal method, by taking up the carrotid and subclavian, (for aneurism, of course, of the innominata,) but without success, as the patient died after the lapse of six days.

27, Acacia Road, Regent's Park, London.

(To be continued.)

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF PROFESSOR SANDS COX, F.R.S., SENIOR SURGEON TO THE HOSPITAL.

Reported by PETER HINCKES BIRD, Resident Medical Officer.

CASE V.

DISLOCATION OF THE SHOULDER FORWARDS.

John Johnson, aged 35, smith, admitted July 10th, 1847, under the care of Professor Cox. He states that about a quarter of an hour ago he was heaving forwards a heavy weight with considerable force, when he felt something "give way" at his shoulder, and immediately lost the use of his arm.

When admitted, the right shoulder appeared much flatter than that of the opposite side; the acromion process was more pointed, and the hollow below it, from the depression of the deltoid muscle, was very considerable; the head of the humerus could be seen just below the clavicle, and when the arm was rotated from the elbow, the protuberance was observed to follow the motions of the arm. The arm appeared slightly shortened; the elbow was separated from the side, and inclined a little backwards; the hand was supinated, and he could not flex his fingers; he complained of some pain, especially on moving the arm forwards; the motion of the joint was very much lessened.

About a year ago he dislocated the same shoulder. The dislocation was easily reduced in the following manner:—The bone was first dislodged by forcible extension, the scapula was well fixed with one hand, and the arm slowly raised perpendicularly by the side of the head, by the other; a peculiar noise was heard when the bone slipped into the glenoid cavity. After the reduction he expressed himself much relieved.

Ordered to use a fomentation of poppy-heads to the shoulder.

12th. Discharged.

CASE VI.

DISLOCATION OF THE SHOULDER FORWARDS.

Emma Standly, aged 20, admitted July 10th, 1847, under the care of Professor Cox. She states that about an hour ago, while haymaking, she was pushed down;* she instantly "felt something give way at the shoulder," and lost the use of her arm.

On admittance, the right shoulder was flattened, and the acromion process prominent, having a hollow space below it; the head of the humerus could be felt below the clavicle, and could be seen to follow the motions of the arm; the elbow was separated from the side, and the motion of the arm forwards caused her much pain. She complained that the fingers were numbed, and also of much pain in the shoulder.

The dislocation was easily reduced, in the same manner as in the above case.

12th. Discharged.

The shoulder-joint enjoys a greater extent and variety of motion than any other articulation of the body, and consequently, its dislocations are more frequent than those of all the other joints taken collectively; those of the ankle-joint being next in frequency. Everything seems, indeed, to facilitate the escape of the bone from its natural cavity; a shallow cavity receives a large head, and is protected only by a capsular ligament, by the subjacent muscles, and by the acromion and coracoid processes; and the bone is exposed more than all others to the effect of the force of external bodies.

The dislocation of the shoulder forwards is much less frequent than that in the axilla; and Dupuytren†

* She fell on her elbow, which was at the time placed rather backwards.

† Clin. Chir., t. iii., p. 102.

believed it to be seldom primary, but almost always consecutive to the dislocation downwards into the axilla; there is now, however, no doubt about the possibility of a dislocation forwards being sometimes primary, and indeed this would be the inference to be drawn from a consideration of the manner in which the accident is caused. In the case of Standly, this dislocation occurred from a fall on the elbow, while separated from the side and inclined backwards, thus forcing the head of the bone forwards, so as to lacerate the capsule in that direction.

After disengaging the head of the bone by extension, a mode of effecting the reduction was employed which was invented by Mr. White, of Manchester, about the middle of the last century, and which has been lately revived by M. Malgaigne, in France. It was the opinion of its inventor, that the success of this method depended on the head of the bone being enabled to get through the laceration in the capsule again; but it depends upon another principle, first explained by Sir Astley Cooper,—namely, the more complete relaxation of the deltoid and supra-spinatus muscles, which latter is the principal antagonist to the reduction. A similar view is also entertained by anothar author:—"If it be true that in some cases the supra-spinatus muscle, retaining its connection with the greater tubercle, is the cause of the resistance to the extending power, it is obvious that this resistance can be best overcome by raising the arm, and thus relaxing the opposing muscle. The success, which not unfrequently attends the method of reduction, first recommended by Mr. White, of Manchester, by drawing the arm directly *upwards*, in a line parallel to the axis of the trunk, *is, no doubt, to be attributed to the relaxation* which it effects of the *supra-spinatus and deltoid muscles.* It is probable, also, that in this position of the humerus, the head of the bone is in some measure unlocked from the neck of the scapula, against which, it is, when dislocated downwards, strongly compressed by the contraction of the muscles."*

Sir A. Cooper considers that the best direction for the extension, is that of a right angle with the body, or quite horizontally, for when the arm is raised suddenly above the horizontal line, and the fingers placed under the head of the bone, the muscles of opposition are relaxed, and the dislocation is easily reduced.

Case VII.

FRACTURE OF THE ACROMIAL END OF THE CLAVICLE.

Benjamin Hitcher, aged 4½ years, admitted an out-patient, January 7th, 1847, under the care of Professor Cox. It is stated that about an hour ago he fell down stairs backwards, and struck his shoulder forcibly against one of the steps.

On examination, there was a slight falling of the left shoulder downwards and forwards, the level of the acromion process being somewhat lower on the injured, than on the sound, side; the motion of the arm was lost. The clavicle was found to be broken near to its acromial end, and crepitus could be distinctly felt; there was very little displacement of the fractured portions. A firm wedge-shaped pad was placed in the axilla, and confined there by means of a bandage passed underneath it; the arm was fastened to the body by a bandage, and the hand and forearm supported in a sling.

10th. Doing well; the fractured portions are in good position; there is some ecchymosis of the shoulder.

30th. The fractured ends are firmly united, without producing any deformity; a ring of callus can be distinctly felt.

Case VIII.

FRACTURE OF THE ACROMIAL END OF THE CLAVICLE.

Elizabeth Swinsborne, aged 9, admitted an out-patient, June 11th, 1847, under the care of Professor Cox. It is stated that about a quarter of an hour since she was pushed down, and struck her right shoulder with considerable force against a stone step.

When admitted, she complained of some pain of the right shoulder; there was no displacement, and she could raise her arm, but not so freely as natural. Fracture of the acromial end of the clavicle was, however, detected, about an inch from the process, for when the fingers were placed over this part of the bone, and the shoulder was raised and depressed, crepitus could be distinctly felt, and no motion could be perceived in the inner portion of bone, but it could in the outer portion. The pad and roller were used as in the preceding case.

12th. The parts about the shoulder are much bruised, but there is less pain.

July 3rd. The bone is firmly united; a distinct ring of callus can be felt about one inch from the acromion process.

The acromial end of the clavicle is comparatively seldom broken, for this part is of a different structure from the centre of the bone, being thicker, and more spongy; it is, however, more frequently fractured than the sternal end, for it is flatter and broader, and very liable to yield to a force directly applied to it.

When the fracture occurs near the acromial end, there is often no displacement, thus occasioning a difficulty in the diagnosis. In the case of Hitcher, the displacement was very slight; in the case of Swinsborne, it was entirely absent. Fracture of this part of the bone is generally produced by a force directly applied upon the shoulder, such as a heavy weight falling upon it; or it may be broken by a person falling on the outside of the shoulder, but in this case the centre of the bone is much more likely to break.

Various reasons are assigned for the absence of displacement in fracture of the acromial end of the clavicle. It is said by some that the trapezius muscle prevents the portion of bone falling; others, more justly, attach importance to the ligaments that pass up from the coracoid process to the under part of the clavicle. But a great deal depends upon the ends of the bones themselves, being more directly locked together when the fracture is in this situation, than when it is near to the centre of the bone; for here the fractured surfaces are broader, and the weight of the shoulder tells more directly against them, and in a

* Crampton. *Dublin Journal of Medical Science*, Vol iii., p. 181.

direction not likely to displace them, owing to the fracture being so near to the scapula. It is said that another reason is, that the deltoid muscle pulls the sternal end of the clavicle, and keeps it on the same level with the other portion; for, as the shoulder drops, and takes the acromial end of the bone with it, the deltoid muscle will at the same time pull upon the sternal portion, and depress it equally as much.

Crepitus is the most sure and decisive symptom of fracture of the acromial end of the clavicle; it can generally be produced when the motion of the portion of the bone is not sufficiently marked to be depended upon; but then it may be confounded with fracture of the acromion process, especially if the person is fat, or there is much swelling present. It is also said that this kind of fracture may be mistaken for dislocation of the end of the bone. The two injuries, however, may be easily distinguished from one another; the prominence in the dislocation is much greater, and the measurement of the bone in the two cases is different. In dislocation, the length from the sternal end of the bone to the prominence, equals the length of the sound clavicle of the opposite side; but in fracture, the distance to the prominence is less, owing to the acromial end of the bone being removed. As, however, in the majority of cases, displacement is absent, measurement is of little use.

The treatment of fracture of the acromial end of the clavicle, is similar to that of fracture in other parts of the bone; it is, however, usually requisite to apply less force, owing to the slight tendency to displacement which exists. A pad, placed in the axilla, and the common figure of eight bandage, will generally be found sufficient.

PROVINCIAL
Medical & Surgical Journal.

WEDNESDAY, OCTOBER 4, 1848.

We would call the attention of our readers to an Act of Parliament just passed, entitled "An Act to Renew and Amend an Act of the Tenth Year of her present Majesty, for the more speedy Removal of certain Nuisances, and the Prevention of Contagious and Epidemic Diseases."

By this useful Act, a very summary plan for removing nuisances is provided. Two householders in the parish or place, are to make the complaint of any nuisance, in writing, to the Town Council, or to the Guardians of the Poor, or to the Commissioners of any Improvement Board, or Paving Board, and either of these bodies is to appoint one or more of their members to examine the nuisance; or else, the certificate of the nuisance, in writing, of two legally-qualified medical men, may be obtained. After either of these steps having been taken, the complaint is to be made before a Justice, who shall summons the owner or occupier to appear before two Justices, who have the power of ordering the removal of the nuisance, under certain penalties for disobedience. Thus, two of the inhabitant householders, with two medical men, can, through any municipal body, or board, or the Guardians of the Poor, compel owners and occupiers to remove nuisances.

These nuisances are enumerated in the Act as follows:—"Foul and offensive Ditches, Gutters, Drains, Privies, Cess-pools, Ash-pits, the accumulation of Dung, Manure, Offal, Filth, Refuse; or Swine, or any other Cattle or Animal kept upon any Premises, so as to be a Nuisance or injurious to the Health of any Person."

It should be remarked, that it is not necessary to prove actually the injury to health in these cases, for whatever is merely a nuisance may be removed. The nose is the great detector of nuisances, and all permanent causes of bad smells which annoy many persons are undoubted nuisances, and must be more or less injurious to health.

By another clause, "the District Surveyor or Trustees is compelled to cause all open Ditches, Gutters, Drains and Water-courses by the sides of Highways, to be cleansed and kept clear. And the owner of any House, built subsequently to this Act, whose Drainage runs into an open Ditch, is guilty of a Misdemeanour."

We are happy to observe a very sensible clause, that none of these proceedings are to be quashed for want of form, and there is no appeal to a higher court.

It is of the utmost importance in rendering this Act effective, that medical men should be aware of its existence, for upon us, as a body, will mainly depend the effectiveness of any sanitary laws. It is our duty constantly to enlighten the public on the causes of disease, as they regard us as authorities on these points, and much more good is done when the adviser is doubly armed,—with the knowledge of the cause, and with the remedy. The Legislature has done its part. It has granted stringent laws, easily put in force. Let us, now, each of us in his sphere, endeavour to promote the execution of these laws; and the cholera may by this means be turned into a source of permanent advantage to this (after all,) splendid country.

Review.

On Functional Diseases of the Liver, associated with Uterine Derangement, embracing the Consideration of Special Physiological and Pathological Relations, hitherto unnoticed. By Butler Lane, M.D., M.R.C.S.E., &c., London. 1848. 8vo. pp. 32.

The object of the author of this treatise is to direct the attention of the profession to a relation which he considers to exist between the liver and the uterus. His own attention was first drawn to the subject during his researches upon the action of oxide of silver in uterine affections, from finding that one form of menorrhagia, in which disease the oxide proved generally benficial, resisted its powers, and that cases of this form yielded readily to mercurial alteratives, the uterine discharge ceasing with the relief of the congested or torpid liver, by copious biliary secretion.

The following conclusions are deduced as the result of the author's experience for three years:—

"1st. In a state of health an anatomical and physiological relationship exists in the female between the liver and the uterus.

"2nd. The relationship in question is apt to be disturbed in many forms of disorder and disease, primarily implicating either organ individually.

"3rd. The disturbance in question, though varying much in nature and degree, assumes certain definite aspects, the recognition of which serves much to direct and facilitate our therapeutic appliances."

Some considerations tending to confirm these views are brought forward, arising out of a comparison of the relative weights of the liver of the male and female, at different periods of life, and the composition of the blood from the portal vein and of the menstrual secretion.

Dr. Lane remarks that, in a great majority of instances it will be found that menstruation rarely occurs without some concomitant alvine derangement. "The bowels will vary from their usual state of action, becoming either confined or relaxed, relatively to their ordinary condition,"—"Assuming, therefore, the existence of an hepatico-uterine relation, it will follow that when the periodical excitement of the uterus takes place, occasioning menstruation, then the liver will manifest some sympathetic influence. If the action should be simply derivative, the biliary secretion will be diminished, and the natural cartharsis will consequently be lessened. But if a greater degree of excitement attend the meustrual period, the liver may even be supposed to undergo a sympathetic degree of excitement or erethism, and its secretion being thereby augmented, instead of being diminished, increased cartharsis will consequently result."

We believe this remark to be well founded, it is at least consonant with our own observations, although not hitherto especially directed to this point. The subjoined summary of 100 cases, in which the author has ascertained the peculiar alvine state at the period of menstruation, is adduced in confirmation:—

"Of 100 females in good average health, 22 acknowledged no change in the action of the bowels during menstruation, though in many of them it is probable there was some slight variation from the usual state, inasmuch as the answer returned to my inquiry was often that the person had '*not noticed*' or was '*not aware*' of any difference in the action of the bowels at those times; in 45 instances comparative constipation was declared to exist during menstruation; and in 33 cases there was relaxation of the bowels in comparison to the usual wont, but in about half these cases there was more or less dysmenorrhœa, whereas, in the females otherwise categorized, the complaint rarely existed. Thus it seemed that any undue uterine excitement or irritation tends to cause relaxation of the bowels during menstruation; and this was countenanced by reference to some cases of special female diseases, uterine tumours, &c., which Dr. Frederick Bird kindly permitted me to make note of; out of 20 consecutive cases I found the bowels were unaffected at menstruation in 4 instances, constipated in 2, and relaxed in no less than 14."

The pathological conditions of the two organs in certain states of the constitution, and more especially at the two periods of the first commencement, and the final cessation, of the menstrual secretive function, tend greatly to establish the existence of the relation which Dr. Butler Lane endeavours to point out. It needs only to refer for example to the frequent co-existence of hepatic derangement with chlorosis, and the relief experienced to both morbid states by the combined exhibition of alteratives and cathartics, in the first instance, followed by steel medicines in various forms; to the connection of headache, vomiting, diarrhœa, and other symptoms of hepato-gastric affection in dysmenorrhœa; and to the extensive disorder of the entire digestive system, often lasting for months, or even years, at what is well-named, in the common language of females, "the turn of life," in which the hepatic functions are especially implicated.

It is unnecessary for present purposes that the subject should here be pursued further. These and other examples of the relationship of the two organs are pointed out and illustrated by cases in Dr. Lane's unpretending pamphlet, and to this we must refer; cordially recommending it to the notice of our readers, as deserving of attention, not only as conveying many useful hints to guide the observation of the physician, but as comprising within the very moderate limits of a brief pamphlet, a subject which many writers, with far less material, would have expanded into an octavo volume.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

June 1st, 1848.

Dr. Percy in the Chair.

VEGETATIONS ON THE MITRAL VALVE.

Mr. Brindley communicated the following case:—The patient was 38 years of age, and of sedentary habits, being clerk to the Birmingham Canal Company. Until two years ago he appears to have enjoyed good health, with the exception of occasional attacks

of bilious dyspepsia, and some rheumatic pains of a temporary character. At this time, being engaged as a brewer's agent, he drank freely of malt liquor, which led to pecuniary embarrassments and much distress of mind, to which conjoint causes he attributed the declension in his health previous to the illness of which he died. This came on with shivering, from exposure to cold, while in a state of profuse perspiration and but partially clothed, about Christmas, and was followed by general aching and soreness, disturbed sleep, and occasionally delirium at night. There was no articular rheumatism. About the end of January, (when I first saw him,) he was emaciated and greatly dejected, complained chiefly of tenderness all over the surface of the body, more especially over the loins, glutæi muscles, and calves of the legs. Locomotion was so difficult and painful, that shortly after he was confined entirely to bed. He perspired freely, the tongue was covered with a thick white fur, and the breath foul, with entire loss of appetite; bowels exceedingly costive; urine scanty, frequently depositing the urates, with no trace of albumen. Percussion good throughout the chest. In the cardiac region there was, perhaps, less than the normal dulness. The heart's impulse was feeble; a distinct but not loud bellows murmur was heard over the whole region, and also in the back, on *both* sides of the spine; *loudest* below, and to the left of the nipple, where it has the *same* character,—systolic, masking the first sound. Respiration normal throughout both lungs; pulse 110, and very weak; some uneasiness occasionally in the cardiac region, with slightly disturbed action of the heart, and slight dyspnœa. Towards the end of February, spontaneous salivation came on, and the ankles were œdematous; he had also some strange mental illusions, fancying himself double, and that sometimes one part of his body, and sometimes another, belonged to some other person, with whom he would often appear to be holding conversation, and it was difficult to retain him long in a proper state of consciousness. In other respects he was much in the same state, with progressive emaciation, profuse perspiration, obstinate constipation, and inability to raise himself or turn in bed. Pneumonia came on a fortnight before death, with cough, rusty sputa, crepitation, dulness, and bronchophony, over the lower part of the right lung behind, extending subsequently to the left lung also. It appeared to be the hypostatic form of pneumonia. Dr. Johnson and Mr. Russell attended the case with me. He died on the 9th of April.

Autopsy twenty hours after death. Body greatly emaciated. *Head* not examined. *Chest*:—Some old celular adhesions between the right lung and costal pleura; its lower and middle lobes were in the second stage of pneumonia, containing, however, little blood, but a large quantity of frothy serum. The lower lobe of left lung was in a similar condition. No effusion into either pleura. No tubercles in the lungs. *Heart*:—Two or three ounces of clear serum were found in the pericardium; heart itself small and flaccid, presented no morbid appearance on its surface or in its substance, and the relative proportion between the size of the cavities and the thickness of the parietes was preserved. The tricuspid and aortic orifices were large. Tricuspid pulmonary and aortic valves sound; the latter unusually large. The mitral valve was the chief seat of disease. A large crop of fibrinous firm vegetations sprang from its parietal flap, and projected towards the auricle. This flap was nearly destroyed, the base of the vegetations taking its place. None of the cordæ were loose. The aortic flap was generally healthy and smooth, the vegetations extending only to its parietal end, close to its juncture with the other flap. The endocardium generally healthy; that of the left auricle more opaque than the rest, and near to the valve roughened by a few small patches of fibrinous deposit. Aorta (ascending and arch,) healthy; no atheroma. *Abdomen*:—The spleen was large, and at its upper end presented a large patch, of a yellowish white colour, and of firm texture, a change of structure frequently observed in this organ. Kidneys nearly double their natural size, congested, of a deep slate colour; the cortical structure greatly enlarged, apparently by a copious whitish deposit, giving to the outer surface a somewhat mottled aspect; the right more advanced than the left. The liver and other abdominal organs sound.

ADHERENT PACENTA.

Dr. Mackay exhibited a placenta, presenting calcareous deposits and fibrous bands upon its uterine and fœtal surfaces, but particularly upon the former. It was adherent to the uterus, and in the act of detaching it, was found to tear with great readiness, so that more than ordinary care was necessary, in order to secure its complete separation and removal, which, happily, was effected, together with the membranes. Soon after the placenta was extracted, notwithstanding that the uterus contracted generally and firmly, hæmorrhage came on, and with short intervals continued to recur for the space of eight hours, during which the amount of blood lost was very great, and the consequent exhaustion proportionately alarming. From the cessation of the hæmorrhage, however, the patient has been recovering, and is now, on the tenth day after her confinement, quite convalescent.

She stated that during the latter half of her pregnancy, she suffered severely from pain and soreness over the fundus uteri, which rendered exertion of any kind, particularly walking, exceedingly distressing, and while she was in bed obliged her to lie in one posture. At her previous confinement, which was her first, the placenta was likewise adherent, and hæmorrhage coming on, as it did on the late occasion, soon after the birth of the infant, the surgeon proceeded to extract it, but unhappily he only succeeded in removing a part, and the remaining portion was not expelled until four days had elapsed, the patient meanwhile being in a state of almost constant syncope, from the vast loss by hæmorrhage, and other uterine discharges, which depressed her as much by their intolerable fœtor, as by their quantity.

The following are the points in this case which appear most instructive, and worthy of attention:—We have here an instance of the placenta being adherent in two successive pregnancies, without any cause which could have led to it being known. Those who have been much engaged in midwifery practice,

are aware that this occurs in some persons in several successive pregnancies; and, consequently, when a person, in whom it has been once observed, becomes pregnant again, it becomes the duty of her medical adviser, to use such precautions as are likely to prevent its recurrence, which, in some instances at least, it is probable may be done. For example, had the subject of the present observations not disregarded the pain she suffered over the fundus uteri, but, on the contrary, had she sought for advice regarding it, and been judiciously treated, it may be presumed that the morbid process would have been arrested, and its important consequences averted. Whenever there is pain and tenderness upon pressure over the situation of the placenta, as indicated by the stethoscope, with or without constitutional disturbance of a febrile character, an inflammatory or hyperæmic condition of that organ may be inferred, and demands appropriate treatment for its removal. In removing an adherent placenta, with other precautions, it is important that in detaching it, care should be taken not to lacerate its substance, so that by examining it after its removal, the operator may be able to ascertain beyond doubt, whether he has succeeded in removing the whole, or not. In the present instance, had the placenta and membranes not been so perfect as to preclude all question upon this point, the manner, severity, and obstinacy of the hæmorrhage which followed, would have justly excited suspicion that part had been left behind, as was the case on the occasion of the previous delivery. Not only would there thus have arisen great additional anxiety to the medical attendant, but likewise, in all probability, additional hazard to the patient, from injury being inflicted by further efforts to remove the portions of placenta supposed to have been left behind.

PEARLY DEPOSIT IN THE LUNGS.

Dr. Mackay also exhibited portions of diseased lungs of a man, aged 34, who, with the exception of a short dry cough, seemed to be in good health, and was able to continue his work, which was laborious, up to three weeks before his death. On one occasion, many years back, after a fall, he had had hæmoptysis. Three weeks before his death, was seized with a frequent distressing cough, which was followed by clear frothy expectoration, some dyspnœa, and pain in the chest; and these symptoms were accompanied by febrile disturbance. In a few days after he first applied for relief, he was so far recovered as to purpose returning to his work very shortly, but he relapsed upon the very day he intended resuming his employment. The symptoms were those already mentioned, and they gradually increased in severity until his death. When he relapsed his chest was examined by the stethoscope and percussion. By the latter, no marked difference was detected in the resonance of any corresponding part of the two sides of the chest, nor did it seem abnormal in any marked degree. By auscultation the respiratory murmur was found to be obscured by mucous and subcrepitant rales, which, varying in the degree of moisture and dryness, pervaded the entire of both lungs; the subcrepitant being most distinct towards their apices.

Post-mortem examination of the chest. No adhesion on either side between the layers of the pleura, nor was there any effusion into its cavities. Both lungs as seen *in situ*, occupy their respective cavities completely; anteriorly their colour is a pale blue, posteriorly a dark flesh colour. Upon the surface of both lungs small elevations may be seen and felt, which are caused by small firm bodies, imbedded in their parenchyma, immediately under the pleura. Similar bodies are found in the substance of both lungs, the right lung being more thickly studded with them than the left; and the apices of both lungs more than the lower portions of either. In the apex of the right lung a cavity large enough to contain a pea is observed. The bodies are homogeneous, of the consistence of fibrin, of a bluish pearl colour, and about the size of peas. They are remarkably uniform in all their characters in the different parts of the lungs.

ICTHYOSIS.

A case of icthyosis was presented by the Secretaries to the Society, occurring in a boy 17 years of age, of very short stature, but of square build, and in very good nutrition. The disease consisted in a black colour and warty state of the cutis of the limbs and trunk. The disease was developed to a different extent in different parts, on the outer aspect of the limbs, and particularly on the outer ankles and dorsum of the feet, and on the front of the lower part of the thighs. It existed as long pedunculated warts, or as thick closely set horny spiculæ, standing erect in some parts a quarter of an inch in length. On the inner aspect of the limbs the warty coating was less thick, or assumed the form of sharp spiculæ, not unlike thick bristles; it was somewhat more sparingly developed on the front of the trunk, and over the upper part of the back especially; between the scapulæ it was nearly absent, leaving a dense irregular cuticle, of a dusky tinge. It covered the penis more sparingly, and existed upon the glans, leaving a small bare space immediately around the orifice of the urethra; in the flexures of the joints, in the axilla, and in the opposed surfaces of the nates, the cuticle was also nearly bare, but in the bends of the elbows and of the knees, rigid and horny in texture. The soles of the feet, and the palms of the hands, the opposed surfaces of the fingers and toes, were also free from the disease, as was the entire neck and face; but the cuticle of the throat was harsh, and he stated that a little of the peculiar formation sometimes appeared beneath the chin. The hairy scalp was covered with a thin coating, of the same nature with the other parts of the body. The diseased formation had everywhere a deep brownish black colour; the hair was long but dry; hair existed on the pubes. There were no signs of beard, but a scanty development of fine hair on the upper lip. This state of the skin first showed itself when he was a fortnight old; none of his family were similarly affected. He has enjoyed good health, perspires on active exertion, and only suffers slight pain and soreness occasionally on the dorsum of the feet, after much walking. The nails were natural.

FUNGOID TUMOUR.

Mr. R. L. Baker exhibited the left hand of a female, aged 68 years, which was removed by amputation

below the elbow, on the 24th of May, for a peculiar-looking fungoid disease of seventeen years standing. It had a spontaneous origin, commencing in a small fixed point, attached to the inner side of the distal end of the metatarsal bone of the middle finger, not larger than a small shot, accompanied with sharp lancinating pains. It gradually increased in size for the first five years, when it had reached the size of a walnut, the pain having much increased in intensity. From this time it remained stationary for seven years, which circumstance the patient superstitiously referred to the efficacy of a charm, which had been applied by a professor of the magic art. At this time, twelve years from its commencement, it began to assume a more active character, and continued to increase rapidly to the time I saw her, a month ago. She states that two years since she was a patient of the General Hospital, and was advised by the attendant to have it removed, but would not then consent. The tumour now presents an enormous mass, of irregular somewhat rounded shape, measuring in its longest diameter seventeen inches round; its structure feels very hard and heavy; in its substance the middle and ring finger are imbedded, so that only the first phalanx is visible; its surface presents a lobulated aspect with a few ulcers, having a dark vascular appearance, from which, during the last six months there has been repeated hæmorrhages of considerable amount, at intervals of three or four days, from which loss, and the intensity of the pain, and constant want of rest, she is now very emaciated and debilitated. There is no inflammation of the absorbents, and but very slight enlargement of the axillary glands. Under these circumstances, I recommended the amputation, as the only means of affording relief to her extreme agonies, to which she readily consented. I performed the operation under the successful influence of chloroform, and up to the present time her general health seems much improved, and the stump presents a healthy granulating appearance.

The weight of the tumour and hand conjointly, is three pounds; the latter, however, is very small, from extreme emaciation. The tumour was fully the size of a fœtal head of full term; the form rather lobulated. It evidently implicated the middle finger alone, of which, the last phalanx only was visible; it had separated this finger from the first finger on one side, and from the ringfinger on the other, very widely, so that there was a distance of five inches between the tip of the middle and that of each of the other fingers respectively; it projected between them, and the integument of the metatarsal phalanx of the ring finger assisted to cover it. It lay entirely on the palmar aspect of the hand. In front, ulceration from the surface had opened a large irregular cavity into the tumour. The substance of the tumour was of a white colour, and contained several small cavities filled with dark coagulated blood; it was dense, but gave way to the finger, breaking up under firm pressure, into a white pulpy matter. On squeezing the tumour, a glairy fluid, much like synovia, issued from the cut surface in considerable abundance. The arm was much emaciated.

Foreign Department.

CLINICAL SURGERY.—THE WOUNDS OF JUNE, 1848.

(Translated from the *Annales de Thérapeutique*, by T. W. Crosse, Esq.)

The wounds we observe at the present time, are different to those of last February, and the atrocities which have passed before us during the four unfortunate days, the 23rd, 24th, 25th, and 26th of June, surpass all belief,—in a country, too, so civilized as France. One can only compare this desire for human blood to a sort of general frenzy, such as one sometimes witnesses in an establishment for the insane. The Caribs, those savages whom Columbus so severely chastised, were assuredly less dangerous, being less refined by the instruction, and corrupt example of civilization. That which relates to the spirit of those deeds to which we have alluded, can only be compared to the denaturalization one meets with, from time to time in our courts of assize, amongst bands of malefactors associated for robbery by means of assassination. Posted behind the windows of houses, the enemies of the Republic have basely assassinated the most experienced generals and superior officers, and at the same time have endeavoured unmercifully to exterminate the citizen defenders of order. They did not spare the worthy Archbishop of Paris; as a reply to the words of peace which he carried to the insurgents, he received a ball in the loins, which proved fatal. In that part of the city which the insurgents have invaded, the ground has been scattered with dead bodies, and rivers of blood have, so to speak, flown past our doors. One is ignorant of the exact number of deaths on both sides; it is estimated approximating at 10,000, and certainly the number is not exaggerated. The number of wounded received into the hospitals amounts to about 1,800, but there are also a great number who had been nursed in the town. One must admit, for the honour of the honest labourers, that if a considerable number of workmen, misled by the enemies of the Republic, have on this account imbued their country in blood, and dishonoured the name of France, a great many others, and indeed the majority, have taken arms for the order and defence of the Republic. Happily, justice and order have triumphed, and one may hope that the foolish attempts of these plunderers and pretenders will not be renewed, energetic measures being taken to crush henceforth similar attempts from their commencement.

At the Hôpital de la Charite, under M. Velpeau.

In the Cephalic Region, all the wounds are situated on the face, and more properly speaking, upon the hairy part, or cranium. The cause of this is, that the volleys of fire upon the head have generally proved fatal at once. The wounds without penetrating may cause death, owing to the proximity of the combatants, and the consequent concussion they produce. A crowd of generals, commanders, and officers, have sunk, merely from balls aimed at their heads by the

insurgents, placed behind the windows of the houses, from which they selected the chiefs of the troops, and cowardly massacred them. On the upper jaw only two serious wounds presented themselves, they are somewhat analogous to each other. In one case, that of a woman, the ball traversed the face from above downwards, and entered the mouth by passing along the palatine arch. In the other case the ball struck the bridge of the nose, and perforating the intermediate tissues, entered the mouth by fracturing the palatine arch. These two wounds resemble in a certain degree those which suicides form, from below upwards, when firing a pistol in the mouth. It is remarkable that these kinds of wounds of the upper jaw, when not accompanied by much concussion or hæmorrhage, generally recover. Sometimes they prove severe by the propagation of erysipelas down the air-passages, On the lower jaw there were two severe injuries; one (produced by a cannon ball or the bursting of an howitzer,) had carried away the whole body of the lower jaw, and a great part of the tissues in the front part of the neck, shattered the tongue, and left uncovered the larynx. This man was wounded at the same time by a ball in the lower part of the forearm, which carried away transversely the skin upon the dorsal surface, comprising the extensor muscles of the fingers, and grazing the bone, without causing fracture. M. Velpeau said he would have amputated this limb, if the wound in the neck had not been mortal. The other case was less severe: it was an extensive fracture of the body of the lower jaw, produced by a blow from a gun fired very near. The case presented a remarkable peculiarity. On his admission, the patient was suffocated, and fell asphyxiated; it was found that this was owing to retraction of the tongue, which, having lost its attachments to the jaw, was carried backwards and obstructed the larynx. It was seized, brought forward and fixed with a thread, and respiration went on very well afterwards. This fact of retraction of the tongue has not probably taken place in any of the people wounded in a similar manner. In the returns of those wounded in 1848, a case occurred to M. Blandin, where the mutilation of the body of the lower jaw was complete, and the tongue remained hanging outside the wound, but nothing is observed relative to retraction. After amputation of the body of the lower jaw, we have never seen retraction of the tongue. It remains therefore to be determined what condition is productive of this phenomenon.

Of Injuries to the Vertebral Column, there are two cases. In one, the ball had struck the lower part of the cervical vertebræ, or the commencement of the dorsal; the spinal cord was injured, and the patient soon died paralysed. In the other case, the missile had struck transversely the first lumbar or the last dorsal vertebra. The spinal cord being injured, the patient had paralysis of all the subjacent parts. This case very much resembled that of the Archbishop of Paris.

In the Thorax, the serious wounds which are at present in the hospital are few, many having died. Generally the balls struck the front of the chest and soon proved fatal. There was one case of simple perforation of the superior lobe of the lung, with the usual symptoms of hæmoptysis, emphysema, &c.

In the Abdomen there were two severe cases of wounds, A man received a ball in the right flank, which passed to the left, traversing in its course the parts contained between the diaphragm and the stomach. The right lobe of the liver was implicated. In the other case, an insurgent was wounded in the fore part of the abdomen, and the peritoneum was exposed. It is expected either that the peritoneum will become gangrenous, or that fatal inflammation will spread from this point throughout the serous cavity.

The greater number of cases are wounds of the limbs, especially of the thigh, leg, and foot. Many are attended with fracture of the bones, requiring more or less severe operations. One of the patients who had been wounded in the thigh, had had at the Tuilleries a ligature applied high up round the femoral artery, and the limb is gangrenous. Amputation was performed at some distance from the groin, but he quickly died. A little "garde mobile" had been thrown out of a second-floor window by one of the insurgents, but only met with some severe contusions, being protected by his lightness and his dress.

(*To be continued.*)

NOTES FROM A PRACTITIONER'S DAY BOOK.*

THE USE OF STOMACHICS IN DYSPEPSIA.

Your heavy feeder's safety lies in his dyspepsia: cure this, and you kill your patient. The man, who takes five times too much nourishment into his stomach, would die at once, if the digestive system would convert it into five times too much blood. He that habitually overfeeds, suffers from a dyspepsia, which prevents more blood than is necessary being elaborated, and is much more frequently the cause of a deficient supply. A certain quack medicine once obtained an extensive reputation for the cure of gout. The Duke of Portland, whom it had benefitted, bought the recipe for two thousand guineas, and made it public. Hence, it was long known as the Portland powder. All who suffered from gout or dyspepsia, fortified their stomachs for the pleasures of the table with this medicine, and agreed that they never felt better or enjoyed themselves more. Somebody, however, at length discovered that no one lived long after being cured by the Portland powder. All died in the course of two or three years, of apoplexy, or an attack of acute inflammation. The tonic action of the bitter ingredients of this medicine had enabled the digestive system to elaborate a larger supply of blood than was necessary, and the brittle vessels of the brain were burst by the distension to which they were subjected, whilst a predisposition to acute inflammation arose from a redundance of organizable material.

A CAUSE OF COUGH.

I was once suffering from an attack of acute pleurisy, with some pneumonia, confined apparently to a limited portion of the lung. For many days I was much

* Continued from page 215.

troubled with irritative cough. This, when moderately quiet, was always excited if I tried to speak in a laryngeal tone of voice. I could whisper for many successive minutes without experiencing any inconvenience, but the instant I attempted to utter a single syllable aloud, a cough was excited, and every effort at a whole sentence was interrupted by a succession of coughs between almost every word. I could not at the time account for this circumstance. The feeling of irritation which excited the cough appeared to reside in the larynx; but I had no reason to believe that there was any mischief in this part. The following is, I suppose, the true explanation:—When speaking in a laryngeal tone of voice, the chordæ vocales are approximated, and, by this means, the aperture through the air-passages in expiration is contracted. Its confinement, therefore, produces pressure on the inflamed pulmonary tissue, a sympathetic irritation is communicated to the larynx, and the cough excited.

INFLAMMATION AND ULCERATION OF THE ŒSOPHAGUS.

A man, aged 65, was ill with an acute ascites, dependent upon some abdominal disease, which a *post-mortem* examination proved to consist of a deposition of numerous malignant tubercles, which studded the greater portion of the sub-peritoneal areolar tissue, the liver, and some other parts. Five days before his death, he first complained of pain in the throat on every attempt at deglutition. The next morning incessant sickness began, the stomach rejecting whatever was introduced into it, together with large quantities of a dark bistre-coloured matter, which was evidently blood, acted on by the gastric fluid. Though he always succeeded on making the attempt to swallow, the effort was of a spasmodic character, and accompanied with considerable pain in the throat and along the sternum. This was generally of an aching character; but the juice of an orange, he told me, caused a smarting, cutting sensation. I examined the throat with the aid of a speculum lamp, and, as far as I could see, the mouth, the palate, the tonsils, and the pharynx were all in a healthy condition. On the fourth day, there was less of the black substance, but he vomited several clots of muco-purulent matter, which exactly resembled the sputa of bronchitis in its later stage. My patient had been gradually becoming weaker from the commencement of this attack, and he died from asthenia on the fifth day. Attempts had been made to support him by means of nutritious enemata; but the fluids could be injected only in very small quantity, and returned the instant the pipe was removed, circumstances which were sufficiently explained by the very contracted state of the rectum and colon which was found after death. Since the commencement of the œsophageal symptoms, those referred to the abdomen had remained in abeyance, and the ascites was greatly on the decrease.

The *post-mortem* examination presented several lesions, but those connected with the œsophagus alone seemed immediately concerned in the fatal result. The whole mucous membrane of this part was in an ulcerated condition, the ulcers appearing of very recent formation, having irregular edges, running into one another, without any appearance whatever of granulation. In some parts the whole thickness of the mucous membrane was destroyed; in others the ulceration was quite superficial. The veins were much congested, and the vessels had given way at intervals, for several points of extravasated blood were found in the sub-mucous areolar tissue. I discovered three or four minute tubercles in the substance of the mucous membrane, but was unable to determine whether they were of a malignant character. These lesions were confined to the œsophagus, for the mucous membrane of the stomach was perfectly healthy, and the pharynx presented no trace of disease.

A brother practitioner requested me to see, with him, a gentleman, who had been ill for several days, with symptoms of a common catarrh, caught, as it was supposed, by his getting wet on a fishing excursion, and remaining for some hours in his damp clothes. He was now becoming much debilitated; and there were symptoms threatening the approach of a typhoid state; whilst the urgency of the case was greatly increased by a difficulty of swallowing, which had recently supervened. I found the patient really more ill than I had expected. The whole mucous membrane of the mouth and pharynx, as far as could be seen, was in a state of superficial ulceration, being of a yellowish grey colour, bleeding readily, and secreting a sanio-purulent matter. This diseased condition terminated in front, exactly at the point where the two lips come in contact on the mouth being closed, so that the outer portion of each lip was unaffected. The conjunctiva of the lids and globe was in the same state, secreting a muco-purulent matter, which gummed the lids together during sleep; whilst a similar condition of the Schneiderian membrane was indicated, by the nasal passages being blocked up by sanio-purulent incrustations. The patient was now sitting in his arm-chair; his manner was hurried and tremulous; and his wife assured us that there had been a good deal of muttering delirium during the night. The pulse was feeble, and the skin cold and clammy. What was at first a mere difficulty of swallowing, now amounted to a complete inability. Wishing to witness the effort, I requested the patient to try some brandy and water; he took a small quantity of it into his mouth, and made a convulsive attempt to gulp it down; but, instead of entering the œsophagus, the whole of it returned by the nostrils. From the symptoms, I could have but little doubt that the mucous membrane of the œsophagus, at least in a great part of its extent, was in a similar condition to that of the mouth and the other parts which had been mentioned. I felt confident, however, that the difficulty in swallowing arose rather from a spasmodic affection of the muscles, than from any mechanical impediment. On this view of the case, we determined upon using active counter-irritation along the neck. On either side, behind the trachea and larynx, and from the angles of the lower jaw to the clavicles, we freely applied the glacial acetic acid, by means of a camel's-hair paint-brush; this produced for a few seconds its usual intolerable smarting, but the relief to the dysphagia came sooner than we could have anticipated, for the patient was able to

swallow immediately after the operation. From this time he had no impediment to deglutition, though the effort was still accompanied with pain. We now prescribed the sulphate of quinine, and allowed our patient as generous a diet as he could be induced to take, with a fair proportion of alcoholic stimuli. The vital powers, which had been fast sinking for want of nutrition, now revived, and we soon ceased to be alarmed about the result. The mouth was directed to be frequently washed with a lotion, composed of the Linimentum Æruginis, lime-water, and laudanum, until returning action, indicated by this application producing pain, warned us to its discontinuance. In about ten days all local symptoms had disappeared, though our patient still remained weak from the effects of his illness.

In his book, "On Diseases of the Stomach," the late Dr. Abercrombie relates the following instance of this, as he calls it, rare affection. "A gentleman, aged 26, came to town in June, 1826, to consult me about complaints in his head. On his journey he thought he had caught cold in crossing the Firth of Forth, and when I saw him he complained of his throat; and there was a glandular swelling on the right side of the neck. His voice was hoarse, with a peculiar husky sound. The fauces were of a bright red colour, without much swelling, but were covered in several places with aphthous crusts. He was at this time not confined, and there was not much fever; but, after a few days, he became more feverish, the other symptoms continuing as before. He was now confined to bed, and actively treated, and after eight or nine days he was much better, so as to be able to be out of bed; but there was still some soreness of the throat, with small aphthous crusts, and a husky sound of the voice. After a few days there was a recurrence of the fever, which now assumed a typhoid type, with considerable appearance of exhaustion. He had some dyspnœa, with much difficulty of swallowing. The attempts to swallow excited sometimes cough, and sometimes vomiting, and by both were brought up considerable quantities of a soft membranous substance. He became more and more exhausted, without any remarkable change in the symptoms, and died at about the end of three weeks from the first appearance of the disease.

"*Inspection.*—The whole of the pharynx was covered with a loose, soft, adventitious membrane, which also extended over the epiglottis; and portions of it were found lying in small irregular masses, within the larynx, at the upper part. A similar membrane was traced through the whole extent of the inner surface of the œsophagus, quite to the cardia. Near the cardia it lay slightly attached, forming a soft continuous mass, about the third of an inch in diameter, and with the œsophagus closely contracted around it. The other parts were healthy."

COLIN ARNECAPLE.

(To be continued.)

General Retrospect.

PHYSIOLOGY.

ABSORPTION OF INSOLUBLE SUBSTANCES.

Although numerous works have of late years been published on the physiology of absorption, this function is as yet far from being completely understood. The parts played by the veins and lymphatics respectively, is still but imperfectly known; and the conditions necessary for the operation of absorption are still undetermined. Professor Oesterlen has made a discovery which, if verified, will completely subvert received theories. Having fed cats and rabbits five or six days consecutively, with food in which charcoal, minutely powdered, had been mixed, he found that on examining the blood under the microscope, particles of charcoal, identical with those which had been ingested, were abundantly visible. The blood was taken from the mesenteric and portal veins. The fluid of the thoracic duct did not contain any, neither did the urine or bile. Charcoal is not the only insoluble substance which is capable of being absorbed. Oesterlen found that Prussian blue can likewise be detected.—*Henle and Pfeufer Zeitschrift.* No. 3, p. 111.

PATHOLOGY & PRACTICAL MEDICINE.

CREOSOTE IN ERYSIPELAS.

During a practice of many years Dr. Fahnestock of Pittsburgh, has been in the habit of using creosote in erysipelas of the face, (as well as of other parts of the body,) in both its simple and phlegmonous forms, confining his local treatment to this article alone; and such has been the success of this treatment, that he states he has yet to witness a case which has not yielded to it.

In every case of local erysipelas he immediately applies the purest creosote, with a camel's hair brush, over the whole of the affected surface, extending it some distance beyond the inflamed part, and at the same time administering a dose of calomel followed by a sufficient portion of jalap to insure free catharsis. This, in the majority of cases, is all he finds necessary. But when the mucous membrane of the mouth and fauces is also affected, he pencils those parts with a solution of the Nitras Argenti, say from half a drachm to a drachm in an ounce of distilled water.

In the phlegmonous form, it will be found necessary to repeat the application more frequently than in the simple, with the addition of a bread and water poultice, applied nearly cold, and well sprinkled with water strongly impregnated with the creosote, or a cloth, kept constantly wet with the solution, especially for the face.

The creosote when applied, should cause the parts to become white immediately; if this does not occur it is not pure. Thus you will perceive that success depends upon having the best quality of oil. It is worthy of remark, that the skin does not become in the least marked by the application, no matter how often it is applied.

Dr. Fahnestock was first induced to make a trial of this remedy, by a remark made by Dupuytren, in a small pamphlet which fell into his hands, in which he supposed it might be a good remedy in this disease.

The result of an extensive and exclusive use of this article in erysipelas, has induced him to place the most implicit confidence in it. He asks the profession to give it a fair trial, confident that whoever once tries it will abandon all other articles in its favour.—*American Journal of Medical Sciences*, July, 1848.

PATHOLOGY AND TREATMENT OF TETANUS.

The points of most importance in a paper on tetanus by Mr. Wilmot, are summed up in the following propositions :—

1. That tetanus depends on irritation, direct or indirect, of the excito-motory system, or true spinal cord, by which it becomes surcharged with motor influence; and that inflammation in or about the cord, or any appreciable lesion, is not an essential condition for the development of the disease.

2. That while we have ample evidence, physiological and practical, that opium is ill-calculated to fulfil the indication in tetanus,—namely, to diminish the excitability of the true spinal cord; until our views become improved, and the knowledge of an anti-tetanic agent ceases to be a desideratum, we are not justified in altogether discarding the drug.

3. That our grand object, in the treatment of tetanus, should be to support the patient's strength by the administration of stimulants and nourishment, with a view to compensate the vital powers for their great exhaustion, consequent upon the expenditure of force by the violent muscular contractions.

4. That as the removal of the exciting cause, once that the first evidence of irritation propagated to the spinal cord becomes manifest, does not in the least degree check the progress of tetanus, nor abate the violence of its symptoms, all operations in traumatic cases are not only unnecessary but injurious.—*Dublin Quarterly Journal of Medical Science*, August, 1848.

INDIAN HEMP IN FACIAL NEURALGIA.

Dr. Ruhbaum, of Potsdam, has made several trials of the Cannabis Indica, in cases of facial neuralgia, with the most satisfactory results. In more than thirty cases great benefit was experienced, and many were entirely cured. Very delicate persons were seized with a little giddiness, lassitude in the limbs, &c.; others were affected in an opposite manner, and evinced great excitement, mirth, and vivacity; but these respective symptoms disappeared after an hour or two, and left no unpleasant sensation behind them. The dose was from sixteen to twenty drops of the tincture, containing about one grain of the resinous extract.—*Medicinische Zeitung*, in *Lancet*.

ON PHOTURIA, OR LUMINOUS URINE.

Cases, however rare, have been cited, in which the urine, as it passed from the urethra, had a luminous appearance. The phenomenon has not been explained, wherefore the following case, with the observations of M. Fallot, will be read with interest :—

A man, aged 60, had for many years, at intervals, passed luminous urine; the luminous appearance was most distinct as the fluid dashed on the ground, but a few sparks were seen in the stream as it passed from the urethra. Examination discovered nothing particular in the fluid, which varied in its constituents according to circumstances.

M. Fallot thinks that these cases would be found to be more common if attention were directed to them, but that as the affection is not accompanied by any notable derangement of health, it passes unobserved. In the case referred to, the patient had never alluded to the circumstance until he was questioned concerning it, in consequence of its being accidentally witnessed by M. Fallot.—*Rev. Med. Chirur.*

SURGERY.

FRACTURE OF THE NECK OF THE FEMUR WITHIN THE CAPSULE : BONY UNION.

Dr. Condit reports a case of fracture of the neck of the femur, in a man, aged 80. The accident happened in May, and the patient died in November following. The following are the *post-mortem* appearances:—

The muscles and other structures around the cervix femoris were more pale than usual; the capsular ligament was entire, giving no appearance of laceration. The ligamentum teres was vascular; the acetabulum was normal in appearance. The neck of the femur was shortened, and the fracture was discovered to be wholly within it. The head of the bone had been broken across transversely, exactly where it joins the neck. The ridge, characteristic of the seat of fracture, had been thrown out, and the re-union was firm for more than three quarters of the circumference of the bone. The limb having been drawn up by the contraction of the muscles, a considerable angle was formed by the head and neck at their point of juncture, but they were as firmly united by osseous formation as if they never were separated. On the upper side, where the fractured edges were not in apposition, union was not yet complete, but ossification was going on upon all the broken surface, and had the patient lived a few months, would doubtless have been perfected. Could the state of the injured part have been by any means ascertained, and had not the condition of the ankle forbidden it, the patient, I think, might safely have walked; there was sufficient firmness at the fracture for the limb to have contributed its share of support to the trunk. From a fear lest some accident should befal the specimen in handling it, I left it with a mechanic to have the head protected by a covering wire. He placed it for safe keeping in a desk in his room, belonging to another man, who, removing the desk in his absence, threw out the bone, supposing it to be of no value; and though diligent search was made, it was not recovered. I had the preparation in my possession for two or three years, and during that time it was shown to many members of the profession, who expressed but one opinion, that it was a case in which a *complete fracture entirely within the capsule was re-united by ossification.*—*American Journal of Medical Science*, July, 1848.

NÆVUS TREATED BY SETON.

Dr. Bellingham reports two cases in which the plan of treatment by seton, as recommended by Marshall Hall, was perfectly successful. The first case, which we give below, sufficiently points out the advantages of the method:—

Mary Magrath, aged eleven months, was admitted with nævi on the face, one occupying the root of the nose and inner angle of the left eye, about the size of the section of a walnut, prominent and purple, and a smaller one was seated on the forehead. A needle, armed with silk, was passed through the base in four different places, and the threads loosely tied, so as to allow of motion. Two more threads were subsequently passed, previously dipped in a solution of nitrate of silver, and in less than two months the tumour had disappeared.—*Dublin Medical Press*, August 16.

QUEEN'S COLLEGE, BIRMINGHAM.

At the late annual meeting of the Governors and friends of Queen's College, Birmingham, at which the Rev. the Vice-Principal presided, the following report was read by Professor Knowles:—

On reviewing the transactions of the past year your Council are happy to have it in their power to congratulate the Governors and friends of the Queen's College upon the very satisfactory progress and prospects of the Institution; indeed, perhaps, in no year has the progress of the educational movement been more varied and important.

The aggregate number of matriculated Students is greater than in any former year. The number registered as studying at Queen's College within the period comprised between the 1st of October, 1847, and the present date, is eighty-three. The number registered as being in attendance on the Medical Classes of the Senior Department is fifty-seven. The number in attendance on the Classes of the Junior Department is twenty-five, and one preparing for Laws. Forty-seven Students have in the above period attended the Medical and Surgical Practice of the Queen's Hospital, and ten at the General Hospital. Of the Students in the Senior Department, twenty-four have been in residence within the walls of the College, fifteen have resided with Medical Practitioners in or near Birmingham, twelve have resided with their parents or guardians, five have been in lodgings, one at the General Hospital, and one at the Queen's Hospital. One is preparing for his Degrees in Law. The number of Students entered to the Junior Department and in residence with College Tutors has been fourteen, and the non-resident Students in the same department eleven.

Your Council have great reason to be satisfied with the reports made to them by the Professors and Tutors of the general good conduct and regularity of the Students. The Chaplain's register shows that the daily attendance at Divine Service has been good, and the attendance of the Students, both Senior and Junior, at the Theological Lectures, quite satisfactory.

The Council have the gratification to state that of seven belonging to the Junior Department who presented themselves in July last at the Matriculation Examination of the University of London, four were placed in the First Class, and one obtained honours in Chemistry.

Considerable additions have been made both to the Museums and Library during the past year, while to afford better and more extensive accommodation, the munificent donation of £1000, presented by your venerated benefactor, the Rev. Dr. Warneford, has been expended in the erection of a new Lecture Hall, Anatomical Room, Chemical Laboratory, and sixteen additional sets of rooms for Students' Chambers.

With regard to the addition to the Museums and Library already alluded to, the Council have the satisfaction to announce that they have been enabled to purchase the whole of the models of Dr. Felix Thibert, illustrative of the Diseases of the Uterus and its appendages, Diseases of the Skin, Diseases of the Eye, Syphilitic Diseases, Internal Pathology, and the Anatomical Lesions of the Diseases of the Bladder, Urethra, and Testes. Of the value of this Museum the following Report will afford the most satisfactory evidence:—

[Here follows a "Report made by the Royal Academy of France on the Preparations of Pathological Anatomy, modelled and published by Dr. Felix Thibert, (author of a new method,) by a Commission composed of MM. Andral, Professor of General Pathology to the Faculty of Medicine, Paris; Breschet, Member of the Academy of Sciences, and Professor of Anatomy to the same Faculty; and Cruveilhier, Professor of Anatomy to the same Faculty."]

To the Library the following valuable books of plates, in addition to other standard works, have been presented by the Vice-Principal:—Alibert's Nosology; Bedloo's Anatomy; Haller's Icones Anat., 11 vols.; Loder's Anatomy, fol., vol. iii.; Cheselden's Osteographia; Sir A. Cooper on Dislocations; and Fischer on the Nervous System.

The regulations of the College of Surgeons not permitting any Professor to hold more than one chair, your Council, with very great reluctance and regret, accepted Mr. Sands Cox's resignation of the Professorship of Anatomy; and upon the recommendation of the Professors, Mr. Langston Parker has been appointed to supply the vacancy.

The Professors having also recommended the Council to repeal the law relative to the appointment of Demonstrator of Anatomy, and that the Demonstrator be henceforth appointed in the same manner as the Professors, and that like them he receive the fees and pay the expenses of his class, and that Mr. Bolton continue to hold the office under this arrangement, your Council resolved that this recommendation be adopted, and that the laws be altered in conformity with it.

Your Council has the gratification of stating that Mr. James Smith Upfill, of Bromyard, has enrolled his name in the list of Governors, and presented a donation of £20 for the general purposes of the College. Your Council take this opportunity of making known the power which is given to the Corporation of Queen's College, by its charter, of holding, for the benefit of the College and Queen's Hospital, not only any amount of personal

property, but also, notwithstanding the statutes of mortmain, other real property to the annual value of £5000.

With regard to the Queen's Hospital, it continues to fulfil in all respects the purposes for which it was opened. It has, indeed, completely established the strongest claims upon the liberality of the public, by the sssistance and relief which it has already afforded to the sick and suffering poor of the town and mining districts. It appears from the last report of the Committee of Council, that 3000 home and out-patients and 1312 in-patients have been entered on the books during the last year, and 72 poor married women were attended in their confinements at their own homes. This return is exclusive of vaccination and minor casualties. Towards the support of the Charity the Medical and Surgical Officers have paid over the sum £499, fees received from students. Your Council, however, regret to be obliged to add, that the Hospital has still to contend with great pecuniary difficulties, but they cannot abandon the hope that its means will gradually become more proportionate to its merits and exigencies.

The Report then alludes to the decease of two of the students; and the valuable services of the Right Hon. the Lord Lyttelton, Principal of the College; of the Rev. Chancellor Law, Vice-Principal; of Mr. Sands Cox, Dean of the Faculty; and of the Professors, Tutors, and other officers of the Institution. It then proceeds:—

Your Committee must further repeat their convictions expressed in former years, that the several Professors, Demonstrator, Tutors, and Masters, have all laboured most zealously in their several vocations, and merit the warmest thanks of the College.

Some new regulations with regard to discipline have been adopted, and to prevent students incurring debt the following Report was presented on the 9th of May, by the Sub-Committee appointed for the purpose, and confirmed by the Council:—

1. By suggesting to each parent or guardian on placing a student at the College, to inform the authorities what sum it is contemplated by such parent or guardian to allow such student for expenses, beyond the necessary and direct payments of the College.

2. By periodically cautioning tradesmen, by a public notice in suitable terms, not to allow of the purchase of articles on credit without the express sanction of parents or guardians, or of some officer of the College to whom that duty shall be specially delegated.

3. By desiring also, through the medium of the same notice, that all tradesmen's bills for articles supplied to students shall be regularly delivered to the same officer, and forwarded by him to the parents and guardians at the end of every term.

4. By furnishing each student on entering the College, with a list of such tradesmen as are sanctioned by the College authorities.

5. By providing in the bye-laws, that all cases of extravagance which become known to the tutors, shall immediately be reported to the Council, and by the Council forwarded to parents or guardians.

6. That every student three times proved to the Council to have incurred debt beyond his means, shall be dismissed.

The Sub-Committee appointed to consider how far the educational plans of the College could be extended, so as to carry out fully the powers granted under the provisions of the Supplemental Charter, and under the warrant under the sign Manual,—namely, "To issue to such persons as may be desirous of becoming candidates for the respective degrees of Bachelor of Arts, Master of Arts, Bachelor of Laws, Doctor of Laws, to be conferred by the University of London, certificates to the effect that such candidates have completed the course of instruction which the Chancellor, the Vice-Chancellor, and Fellows of the said University by regulation in that behalf shall have determined," made their first Report on the 22nd February, and on the 3rd of June a further Report. (These Reports have already appeared in our pages.)

Your Council have the pleasure to announce that thirty sets of separate rooms for the reception of the Junior Department, are in a state of considerable forwardness, and rooms will be ready for occupation in October for the Department of Arts; and it will be one of the first duties of the Council to proceed to the election of a Senior Classical Tutor, a Senior Mathematical Tutor, and a Junior Classical Tutor.

Your Council are unable to present to you the names of the several successful candidates for Scholarships and Prizes, as the Warneford and Jephson Prizes are still under consideration; but an early report will be published.

Having thus shortly mentioned the most important occurrences of the year, the Council close their twenty-first annual Report, with an expression of a deep sense of thankfulness to the Giver of all good, for the success and prosperity which has attended the Institution, in a degree which its most sanguine friends could hardly have anticipated.

After the Report had been read, votes of thanks were passed to the Officers, to the Professors, Tutors, Demonstrator, Masters, &c. The meeting then proceeded to elect by ballot the Officers for the ensuing year, and was afterwards adjourned for the distribution of the prizes.

POISONING BY BELLADONNA.—CASE OF THOMAS GREAVES.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The interests of the medical profession, and of public justice and safety, require some remarks from me upon the communication of Mr. Law, in your last Journal. They shall be brief and as much as possible to the purpose, and on my part, final.

For the credit of a valuable public Institution, especially as regards its dispensing department, I purposely abstained in my former communication from precise allusions. Mr. Law has raised the veil, and exposed to the profession, what is (or at least has been,) the practice at the Sheffield General Infirmary, in sending out its medicines.

I trust, Mr. Editor, as public censor, you will exercise your privilege in suitably animadverting upon proceedings so dangerous to public safety; for we have too much reason to believe that this is not the only instance of the kind from which dangerous, if not

fatal effects have resulted. Mr. Law, as House-Apothecary of the Sheffield Infirmary, undertakes to prove, (*i. e.*, tries to prove,) that Thomas Greaves' death did not result from belladonna. This fact must be borne in mind. Now, he proceeds upon the imperfect evidence produced at the inquest. A witness of unimpeachable veracity, (not called at the inquest,) kindly visited the deceased several times during the seventeen hours of his sufferings, and gave clear testimony of the condition of the poor man; and from her statement, there were present every sign and symptom of poisoning from belladonna, in so far as a non-professional person could appreciate or describe those symptoms. For those symptoms permit me to refer your readers to my former communication. I may further state, that Thomas Greaves was in his usual infirm state of health up till the moment of his taking the poison. He went to the hospital, (a distance of about half a mile,) that day, remained there some time, and brought home with him some pills, a plaster, and a box containing five drachms of extract of belladonna. No written directions accompanied the medicine. The belladonna was supposed to be an electuary; and no doubt the quantity taken was as much as is usual in cases wherein an electuary is the form of medicine prescribed. Mrs. Taylor appeared, in her evidence, to be particularly solicitous to represent the quantity taken to be the smallest bit in the world. We can easily conceive that *she* had a bias in the case; and of course wished to free herself of all blame. Upon this point the case of Thomas Greaves turns. I have observed before, that the deceased was up till the time of taking the extract, as well as usual, and the alarming symptoms supervened almost immediately afterwards, and continued unabated till his death, a period of seventeen hours. Mr. Law remarks, that nausea, which characterizes poisoning by belladonna, was absent. We have undoubted evidence that it was present, and from the testimony even of Mrs. Taylor, that it amounted to vomiting after taking a dose of castor oil. The witness, to whose evidence I before alluded, also testifies to the presence of nausea during the night, when Mrs. Taylor was not present. I regard the appearance of the mucous coat of the stomach, as beautifully characteristic of the effects of the class of poisons to which belladonna belongs—the narcotico-acrid. There had evidently been some highly irritating influence exercised upon the inner part of that organ.

Without going into the minute pathological inquiry as regards the *post-mortem* appearances of poisoning by belladonna, or mystifying the subject by conflicting authorities, miraculous escapes, and various opinions as to the doses and effects of these deleterious drugs, allow me to appeal to the common sense of the profession, as to whether the death of Thomas Greaves, an infirm man of 75, was, or was not, under all the circumstances of the case, the result of a fatal dose of belladonna.

WILLIAM JACKSON.

ACTION FOR MEDICAL ATTENDANCE IN THE COUNTY COURTS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The following case occurred in our County Court, at its last sitting, and I shall feel obliged by your giving it a place in your Journal, with any remarks that you may think proper.

The facts of the case are these:—In November last, my attendance was requested early in the morning, upon Mrs. Whitham, in consequence of symptoms threatening premature labour, and I remained at home during the day specially on her account: under treatment the symptoms disappeared. In December, my attendance was again requested under similar circumstances, and in consequence of these two attacks, I continued to visit Mrs. Whitham at intervals for some time. During this time, Mrs. Whitham's brother, who had formerly been an assistant with me, came down from London, with a view to join me in partnership. The agreement was not entered into, and he set himself up in this place to practise his profession, and, without any notice to me to discontinue my attendance, was engaged to attend, and did attend his sister in her confinement. I made an additional charge of two guineas to my bill for the loss of time, which was disputed, and the present action brought to recover. In reply to the following question by His Honor—"You have heard the circumstances of this case, do you consider the charge of £2. 2s. reasonable or unreasonable?" Mr. Lee replied that, "he considered Mr. Skevington's charge perfectly reasonable—in fact, not sufficient to remunerate him for his loss of time in the case. The defence set up was, that it was not the usual practice of the place to charge for attendance. Mr. Whitham, sen., the lady's father-in-law, was asked by His Honor "whether he should have objected to pay this claim if Mr. Skevington had attended his wife under similar circumstances, to which, after *considerable hesitation*, he replied, "I should.

In summing up, His Honour remarked, that, "he thought plaintiff was entitled to remuneration, though, as he did not attend Mrs. Whitham at her confinement, he thought not so much as claimed for; he should therefore allow him one guinea."

Now, Sir, I should like to have your opinion, with that of my brother practitioners, how far it is consistent for a lawyer, after admitting that I was entitled to remuneration, after hearing from a resident practitioner (and the other medical men would willingly have borne the same testimony, but were prevented attending,) that my charge was perfectly reasonable, to curtail that charge just one half. This may be law, but it is threadbare justice.

I am, Sir,

Your obedient Servant,

JOHN SKEVINGTON.

Ashbourn, Sept. 26, 1848.

[The decision of the Court is manifestly erroneous. The defence set up was "that it was not the usual practice of the place to charge for attendance," not that the charge made was unreasonable, and the judge should

either have directed a nonsuit, or awarded the whole amount claimed. The defence, however, necessarily broke down from the nature of the case; but unable, it would seem, to comprehend the clear and intelligible principles on which the merits of the case rested, the judge travelled out of his record, and took upon himself to estimate the value of time in a profession, with the labours and duties of which he could have but a very imperfect acquaintance. The consequence was, that, notwithstanding the evidence of a competent witness to the very point, he allowed himself to act upon a partial and ill-founded opinion of what is right between man and man, and ingeniously, as a lawyer, if not equitably, as a judge, thought to adjust the doubts of his own creation, by simply splitting the difference!]

Medical Intelligence.

GENERAL BOARD OF HEALTH.

The Queen has been pleased to constitute and appoint Anthony Ashley Cooper, commonly called Lord Ashley, and Edwin Chadwick, Esq., C.B., to be members of the General Board of Health.

THE CHOLERA.

Dr. Sutherland, of Liverpool, and Mr. Grainger, have been sent by Government to Hull, to investigate certain fatal cases, reported to be cases of cholera. They are to proceed thence to the Continent before they make their report. The following order in Council appeared in Friday night's *Gazette*:—

At the Council Chamber, Whitehall, the 28th day of September, 1848, by the Lords of her Majesty's Most Honourable Privy Council—Whereas by an act, passed in the last session of parliament, intituled "An Act to renew and amend an Act of the tenth year of her present Majesty, for the more speedy removal of certain nuisances, and the prevention of contagious and epidemic diseases," after reciting, that it is expedient that when any part of the United Kingdom shall appear to be threatened with or affected by any formidable epidemic, endemic, or contagious disease, measures of precaution should be taken with promptitude, according to the exigency of the case, it is enacted, that, in Great Britain, the Lords and others of her Majesty's Most Honourable Privy Council, or any three or more of them, (the Lord President of the Council, or one of her Majesty's Principal Secretaries of State, being one,) may, by order or orders, to be by them from time to time made, direct, that the provisions in the said act contained for the prevention of epidemic, endemic, and contagious diseases be put in force in Great Britain, or in such parts thereof, or in such places therein respectively, as in such order or orders respectively may be expressed, and may, from time to time, as to all or any of the parts or places to which any such order or orders may extend, and in like manner, revoke or renew any such order, subject to revocation and renewal as aforesaid, every such order shall be in force for six calendar months, or for such shorter period as in such order shall be expressed:

And whereas the United Kingdom appears to be threatened with a formidable epidemic disease, in consequence of the progressive advance of such a disease to the western portion of the Continent of Europe, and a case has arisen for putting in force the provisions of the said act:

Now, therefore, it is hereby ordered by the Lords and others of her Majesty's Most Honourable Privy Council, (of whom the Right Honourable Viscount Palmerston, one of her Majesty's Principal Secretaries of State, is one,) in pursuance and exercise of the powers so vested in them as aforesaid, that the provisions contained in the said herein-before-recited act, for the prevention of epidemic, endemic, and contagious diseases, be put in force throughout the whole of Great Britain immediately from and after the date of this order.

And it is further ordered, that this order shall continue in force for six calendar months, from and after the date hereof.

C. C. GREVILLE.

APPOINTMENTS.

Joseph Noble, M.D., of Dunwich Hall, and John Barclay, M.D., have been elected Physicians to the Leicester Infirmary; Dr. Noble in the room of Dr. Freer, resigned, and Dr. Barclay, in consequence of a resolution to increase the Medical Staff of the Institution to three physicians and three surgeons.

OBITUARY.

Died, August 20th, at Malta, W. C. Watt, M.D., Deputy Inspector of Hospitals and Fleets.

September 3rd, at Chester, John Edward O'Reilly, M.D., of Trinity College, Dublin.

September 4th, at Clifton, aged 82, Robert Lindoe, M.D.

September 10th, at Stonehouse, aged 60, Thomas Millar, Esq., Deputy Inspector of Hospitals and Fleets, and Surgeon of the Plymouth Division of Royal Marines.

September 13th, at Balgarvie House, Fife, David Dyce, Esq., Surgeon to the 48th Regiment.

September 16th, at Beckenham, aged 49, William Merrick, Esq., Surgeon.

September 17th, at Sleaforth, Lincolnshire, Thomas Jacobson, Esq., Surgeon.

September 18th, at Liverpool, aged 74, John Callan, Esq., Surgeon, R.N.

September 22nd, at Staines, aged 69, John Winstone, M.D., late of Charter House Square, London.

Lately, at Edinburgh, William Campbell, M.D., author of several works on Obstetric Medicine.

ERRATUM.

Page 532, column 1, line 19 from the bottom, for "1832 and 1833," read 1842 and 1843.

TO CORRESPONDENTS.

Communications have been received from Mr. T. W. Crosse; Mr. W. Jackson; Mr. Skevington; Dr. R. L. Williams; Dr. M. Duncan; Mr. J. W. Beaumont; Mr. G. Ross.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

RETROSPECTIVE ADDRESS.

Delivered at the Seventh Anniversary of the

READING PATHOLOGICAL SOCIETY,

June 21st, 1848.

By Charles Vines, Esq., Surgeon,

I.—Diseases of the Nervous System.—*Epilepsy—Cerebral Softening—Nervous Depression—Tetanus—Hydrophobia—Mania—Spinal Irritation.*

Mr. President and Gentlemen,—

In appearing before you this evening to fulfil the task imposed on me by your kindness at the last meeting, from which I was unfortunately absent, I must confess how little qualified I feel for the undertaking, but I should be ungrateful were I not to respond to your call,—ungenerous, were I to flinch from a duty which others have so willingly performed.

To give form and expression to the spontaneous efforts of one's own mind, is, perhaps, less difficult than to decypher and arrange the ideas of others; but this part of the work has been greatly facilitated through the labours of our esteemed secretary, Dr. Woodhouse, to whom we are very much indebted, not only for the industry and talent displayed in the arrangement of the minutes, but for the punctuality, zeal, and kindness of that gentlemen, in the performance of a duty involving so considerable a share of time and trouble. Trusting then that you will, pass over my imperfections, (for I fear I shall scarcely do justice to all the communications,) and stimulated by the bright example of my predecessors, whose annual addresses have afforded us so much pleasure, I cheerfully undertake to bring before you, in as concise and clear a manner as I can, the proceedings of our Society during the past year.

The Reading Pathological Society has now completed its first septenary, and I appeal to the members present if, during the seven years of our existence, much mental gratification, and I would fain add, profit, has not been derived from our periodical meetings and transactions.

We must each, I think, be sensible of some hint received,—of some knowledge gained from our fellow-labourers, in the same field. Besides acquiring a familiar acquaintance with the pathological specimens constantly presented to us, we arrive at the proximate cause of disease, and are enabled to wield our weapons, and apply our researches, with greater precision. Mr. Simon, of St. Thomas's Hospital, in his inaugural address, says,—"Eminently true is it of our profession, that the fears and solicitude with which we approach the treatment of disease are in exact proportion to our ignorance of its causes; as these escape us we are bewildered and alarmed; as we detect them we are reassured and encouraged."

I will proceed, now, to the history of the cases, morbid specimens, &c., taking them in the order followed by my predecessors.

I.— Diseases of the Nervous System.

Our reporter of last year had occasion to regret that there existed a paucity in the details of this class of diseases; this year the report of nervous diseases has been both numerous and interesting.

Epilepsy.—On the 28th of July, 1847, Mr. Walford made some remarks on a case of epilepsy. A man, suffering from severe attacks of that malady while under the care of Mr. Walford, was transferred to Mr. J. Workman, the district surgeon. The patient recovered so far as to be able to go to work in the hay-field, after which he was one day seized with violent convulsions, and died the next morning. On examination after death, the brain was found extensively diseased. The case was interesting, as showing the great amount of disease which may co-exist, with very slight impairment of the mental functions. Mr. J. Workman, who made the *post-mortem* examination, stated that the membranes of the brain were much thickened; there was a large abscess of the substance, and a quantity of recent blood had exuded from the ulcerated vessels.

Cerebral Softening.—Dr. Cowan remarked that the most constant symptom he found in similar cases, was an unceasing pain of the head; sometimes localized, at others diffused, with great tendency to coma. He mentioned an analogous case, in a young lady, of strumous habit, aged 25. About six months before death, she had pleuro pneumonia on the right side; three months after a similar attack in the left. After this she complained of distressing headache, particularly about the ears; delirium; difficulty of swallowing; great irritability of the vocal organs, with tendency to talk. The *autopsy* showed much venous congestion of the brain, with a small portion of fluid in the ventricles; softening of the internal structures, the optic thalami, septum lucidum, and fornix, with great congestion of the choroid plexus and velum interpositum; the lungs universally adherent, and milliary tubercles

studded throughout their substance. She died in a fortnight.

This case is an important one, and gives rise to an interesting physiological question,—was the lung disease dependent on vitiation of the cerebral organ? Experiment proves that pneumonia will follow an injury of the par vagum.

Nervous Depression with Delirium.—On the 25th of August, 1847, Mr. Harrinson read the following cases, which had recently occurred in his practice:—

Case 1.—A railway engineer, addicted to spirit drinking, was seized suddenly with convulsive fits, probably epilepsy; subsequently vomiting, extreme exhaustion, and delirium tremens. The treatment consisted in the administration of ammonia, potash, and opium; mustard cataplasms to the epigastrium; beef tea, and brandy and water to support the failing powers. He became comatose, and died somewhat suddenly on the third day.

Case 2.—A young man suffering from a severe attack of pleuro-pneumonia, was treated antiphlogistically for ten days, during which the chest-signs daily improved; he then commenced taking the hydriodate of potass. Five days afterwards, sudden prostration, rapid pulse and delirium came on, threatening speedily to annihilate the vital powers. Stimulating cataplasms and liniments were applied to the surface of the body; wine, brandy, and beef tea freely administered internally. The nervous equilibrium was thus restored, and the patient eventually recovered.

Case 3.—Mr. Harrinson was called during the night of August 7th, 1847, to Mr. B., who had been drinking brandy and water for nine days and nights consecutively, and taking no food. The symptoms were stupor, heat of head, vomiting, full pulse, dry and furred tongue, constipated bowels, urine free and clear. The treatment consisted of effervescing medicine, with ammonia and small doses of tincture of opium, beef tea, with a limited supply of brandy, cold affusion of water on the head, mustard and bran cataplasms to the stomach, and aperients. As the stomach continued irritable, enemas were exhibited. The patient continued in this state five or six days, but gradually losing strength. The matters vomited became like coffee grounds. The catheter was required, and the urine found to be highly albuminous. Low muttering delirium took place, and the extremities began to get cold; the head was still hot; face red; eyes ferretty; pulse full. Dr. Cowan, who now saw him, in conjunction with Mr. Harrinson, proposed cupping to a few ounces at the nape of the neck, and croton oil. The pulse fell, slight convulsions occurred, and the patient somewhat rapidly sank.

The recital of these interesting cases elicited the following remarks from Dr. Cowan, who, having visited the last case, said that delirium and depression from the use of ardent spirits, were happily, not often met with now in this neighbourhood; but in America, where they had opportunities of studying every phasis of its character, it is said by some writers to have a certain period or course, and that it generally terminates in seventy-two hours, or three or four days if left to itself;—that when opium does good it is within the first twenty-four hours; but that this drug was not now found so generally useful, or so much relied on as formerly.

Traumatic Tetanus.—Although the two following cases might, perhaps, have been more properly classed with the surgical or accidental cases, I have thought it better to place them here:—

On the 22nd of September, 1847, Mr. May read two interesting cases of traumatic tetanus, which had recently been treated by him in the Royal Berkshire Hospital. The first, that of F. P., was admitted with a wound from a hook below the axilla, by which the inner head of the triceps was lacerated. On the tenth day, symptoms of tetanus set in. The line of treatment pursued was anodyne, with æther, prussic acid, tobacco, and electricity, but without benefit, death resulting on the 6th day, which is the usual period, or within the tenth. The second case was that of J. H., who received an injury to the finger from an iron nipper. The finger was removed a few days after. Tetanus set in on the tenth day after the accident, and third after the removal of the finger. He died on the seventh day of the disease. On examination after death all the viscera, with the spinal cord, were found healthy.

Mr. May, in his remarks, said that these were cases of simple traumatic tetanus, as distinguished from the inflammatory form. The disease occurred about the usual period,—viz., the tenth day; and before the wounds were healed, which is generally the case, there was the præcardial pain, which is said to be pathognomonic of the disease, though denied by Dr. O'Beirne, of Dublin, who says there is a particular expression of countenance, which he considers peculiarly indicative of the malady. Dr. Parry, of Bath, states, that if the pulse remain below 100 up to the fourth day, the case will recover; but this opinion was not verified in the foregoing instances. Mr. May thinks Dr. Parry may not have distinguished the inflammatory form from the irritative. Æther and tobacco were used, without benefit. Electricity afforded no essential relief. This is not a new remedy, some gentleman wrote upon it hundred years ago; and Mr. Adams has recorded two cases which appeared to derive benefit from it. Opium has been largely used in this malady, but not with the same confidence as formerly. Dr. Budd speaks against it, says it stimulates the cord. Mr. Francis, and others of large experience, are not in favour of it. Hydrocyanic acid is said by Mr. Curling to be a stimulant of the spinal cord also. The mode of death was by syncope and exhaustion. There was none of that spasm of the glottis in this case, which is often said to be the cause of death, so as to suggest the opening of the trachea. On inspection after death there was ecchymosis of the muscles of the back, different from the usual effect of gravitation. There was some congestion of the vessels of the cord and membranes, but no inflammation nor softening of the cord itself, which justifies the notion that it was irritation, not inflammation. Mr. May was inclined to coincide in the general opinion that tetanus is a functional disease of the nervous system, particularly of the motor tract. In these cases there was no fever, delirium, or acute spinal

pain, which, probably, *would* have been the case, had there been inflammation of the cord or its membranes. As to the local treatment, Mr. May is favourable to amputation, where the operation can be performed without risk, which opinion is somewhat confirmed by the cases given by Dr. Wallace, of Dublin. The division of a nerve or nerves has been also recommended. Mercury is generally useless or injurious in the irritative form, but of great benefit in the inflammatory. Cold affusion has been used, but without any benefit. Warm baths are generally used, but were of no service here. Carbonate of iron has been recommended by Dr. Elliotson; his cases were, probably, idiopathic.

Professor Sewell, who was present on the occasion, said he had heard of cold affusion having been used by Dr. Jackson, in 300 cases, without benefit. In horses, where tetanus after injury is a frequent occurrence, he would recommend the excision of the nerve in every case. A drummer at the Cape was treated successfully, by division of the nerve. Professor Sewell once injected tepid water into the juglar vein of a horse labouring under tetanus: it produced perspiration, purging, and immediate recovery. He had not used medicated injections. He had used "*woorara poison*" in three cases. Artificial respiration should be kept up for four hours. Ætherization had no effect. In all horses the natural beat of the pulse was 32 in a minute; when at 40 he abstracted blood. Warmth was well supplied, or produced by a fresh sheep skin, and blanket clothing. He used setons along the spine, but *not* the cautery. The spinal marrow in tetanus was congested *not* inflamed. He had more confidence in the injection of warm water after the division of the nerves than anything else. In hydrophobia, he added, transfusion was our only chance. He should take away as much blood as possible, (believing it to be poisoned,) and then transfuse fresh blood from another animal. It was only necessary to transfuse half the quantity of that taken away. He believed that the carniverous species alone were liable to hydrophobia, and that it originated in dyspepsia. It was very important to bear in mind, that a dog might transmit the disease, without at that time showing it himself. In hydrophobia there was intense inflammation of the spinal cord, of the nerves wounded, and also, but in a less degree, of the brain itself. He kindly promised to present to the Society some drawings shewing the pathological states and differences of tetanus and hydrophobia.

On the 20th of October, 1847, Professor Sewell exhibited drawings of the spinal cord in tetanus and hydrophobia. In the latter instances, the cord, nerves, and membranes, were highly inflamed. In the former they were only congested. When the bite was in the hind extremities of an animal, the inflammation was most intense about the sacrum; when in the fore limbs, it was most violent in the anterior parts. One specimen shewed the violent inflammation of the interior of the column, and of the nerves proceeding from it, while the exterior was white. Another drawing exhibited a good deal of black deposit on the upper part of the column, in two coach horses, who were bitten by a dog in the same night, and who died within twenty-four hours of each other. A third drawing represented the interior of the heart, where there was a large clot of blood effused beneath the endocardium, which he invariably found in all cases of sudden and violent death, tetanus, hydrophobia, or from over-exertion. There was also a view of a portion of the spine of an infant, bitten by a puppy which was *not mad*, yet hydrophobia followed, of which the child died. He enumerated five instances of the disease produced by dogs, who presented *no* signs of madness, yet hydrophobia followed their bites. Rats, in a state of excitement, and cats, will produce hydrophobia by their bite.

A vote of thanks was unanimously accorded to Professor Sewell for his valuable drawings, with the hope that he would favour the Society with his presence as long as he remained in the neighbourhood, which he kindly promised to do.

Mania.—On the same evening Mr. May called the attention of the Society to the subject of mania, and among other interesting cases, related the following:—

A clergyman in the neighbourhood was seized with mania, whilst performing service in the church. He became perfectly deranged, at first believing himself to be the Saviour come to judge the world. Afterwards the mania degenerated into the lowest form, using the most obscene language. He died in ten days. About the third day of his illness, a sister, who resided in Hampshire, came to see him. She became affected with mania, and precisely the same symptoms were manifested. Mr. May considered the latter case hysterical, poured cold water on the head till an impression was made on the system, and then gave a drachm of laudanum. In two hours the patient fell into a sound sleep, which lasted several hours, and awoke quite recovered. There has been no return of the symptoms. On examination of the brother after death, the brain was found to be highly congested, but not inflamed.

We have cause for congratulation that the treatment of mental diseases has received far more attention than formerly, and in proportion have the results been more successful; that the strait waistcoat and other more severe means of restraint, are not now the remedies to be relied on, but a higher and more refined system of treatment, the moral and religious training of the mind.

Spinal Irritation.—On the 24th of November, 1847 Dr. Wells read an interesting and practical paper on spinal irritation. After alluding to the frequent occurrence of the complaint, he mentioned the presumed causes:—1st. An alteration in the capilliary circulation of some part of the cord. 2nd. Rheumatism, affecting the cord, locally or generally. Dr. Griffin's views were next examined, as to the source of irritation—the origin of the morbid process, which he believes to exist in the cord itself. Dr. Wells very much doubts whether spinal irritation be ever a primary idopathic affection, and says, may it not be rather presumed that it owes its origin invariably to an impression made upon the incident excitor nerves, coming from a viscus, the subject of a morbid irritability, and that all the anomalous effects are produced through the reflex functions of the spinal cord? Among the cases selected to elucidate this view of the subject, was one in which

the spinal irritation owed its commencement to indigestible food taken into the stomach,—others in which the derangement of the catamenial functions was supposed to have originated the spinal affection. The limits of the present address will not allow me to notice this excellent paper more in detail.

(To be continued.)

CASES OF OXALURIA.

By P. Martin Duncan, M.B., Physician to the Essex and Colchester Hospital.

The following cases, with several others of which I could not obtain notes, have come under my notice, during the last three months. With one or two exceptions, the disease was of long standing, but yielded readily to the treatment so ably recommended by Dr. Golding Bird.

Case I.

Sarah Watts, aged 23, single, subsists by washing, and is necessarily exposed to considerable variations of temperature. Before her illness she worked long and late, had no regular time for her meals, and but a scanty and not over nutritive diet. In April last her appetite failed her, she suffered from pain in the stomach after eating, and was rarely free from frontal headache, nausea, and a sensation of weight in the loins. These symptoms persisted until the 28th of July, when she came under my care.

She is a stout well-made woman, with regular uterine functions; has a sallow and depressed expression of countenance, and slightly jaundiced conjunctiva; tongue large, fissured, and red at the tip; mucous membrane of the lips rather colourless. Has little or no appetite; suffers greatly from gastralgic pains, and has a constant sensation of nausea. She sleeps badly; has severe frontal headache; is morose, desponding, and very irritable; bowels open daily; organs of respiration and circulation healthy; no increase in size of any of the abdominal viscera. Has a constant sensation of uneasiness and weight in the loins, and passes a considerable quantity of amber-coloured urine, of specific gravity, 1.016, which deposits, on standing, a slight cloud of mucus. The microscope distinguished numerous crystals of the oxalate of lime, numerous nucleated cells, and a quantity of amorphous urate of ammonia. The urine examined was passed in the middle of the day. Ordered her a light and mixed diet, to leave off work, and to take, every other night, Pil. Hydrarg., gr. v., formâ pilulæ. R. Acidi. Hydrochlor., Acidi Nitrici, utrq., m. ij; Infus. Quassiæ, oz. j. Misce fiat haust ter.

July 31st. Feels much better; pain in the head and loins less. Rept. medicamenta

August 7th. Greatly improved; no trace of the presence of the oxalate. Pergat.

14th. Feels nearly well. Omitt. Pil. Hydrarg., et capt. Pil. Rhei. Co., gr. x.

21st. Complains of gastralgia, otherwise looks well; has a good appetite; urine acid, of specific gravity 1.019; no oxalates. R. Argenti Oxidi, gr. ½; Extr. Hyoscy., gr. iij. Fiat pilula j., ter die capienda.

The next report finds her well.

Case II.

Sarah Clarke, aged 48, has suffered for five years from psoriasis in the face, and of late has lost flesh and appetite. She has been constantly under medical treatment, and has been but little benefitted. When I first saw her, she was taking senna and aloes during the day, and a diaphoretic at night. She has a good rotundity of figure, regular catamenia, and appears to have suffered a martyrdom from dyspepsia. She complains of severe frontal headache, flushes of heat in her face, dull aching pains in the loins, and total loss of appetite. Her tongue is foul, breath fœtid, and bowels constipated; sleeps badly, has horrid dreams, and generally feels a sense of impending evil. Has not energy to work, nor to keep her person over clean. Ordered her to bring me some of her urine, and in the mean time to take Mist. Gentian. Co., oz. j.; Magnes. Sulph., dr. j. Fiat haust. ter die sumend.

August 28th. Much the same; the bowels, however, are well open; tongue clean; eruption in face not so well. Urine passed in considerable quantities, pale, acid, of specific gravity, 1.024; contains a great number of octohedral crystals of the oxalate of lime, little epithelium, and a considerable quantity of urate of ammonia. Ordered a light diet. R. Acidi Hydrochlor., Acidi Nitrici, utrq. m. iij.; Infus. Quassiæ, oz. j. Fiat haust. ter die sumend.

September 11th. Has improved greatly during the last fortnight. Her general appearance is much improved, her spirits are better, and she says her desponding thoughts have left her. Pain in the loins and head gone; bowels regular; eruption in the face persists. Urine pale, acid, of specific gravity, 1.016, contained urates, but no oxalate of lime.

23rd. Discharged cured.

Case III.

Jane Taylor, aged 19, has been ill for some months, but never thoroughly well during the absence of the catamenia, a period of three years. Has been out at service, and having had the care of several heavy children has suffered accordingly. She is a tall slow-moving girl, silent and sulky, answering with manifest disinclination. Suffers constantly from frontal headache and intense pain in the stomach after eating. Pain in the loins and weakness in the legs are also prominent symptoms. Sleeps well but rises unrefreshed; her appetite is very great, and gives her no satisfaction; says she passes a large quantity of urine, being frequently obliged to get up of a night to do so. Bowels constipated; skin dry and harsh, and says she never perspires; pulse 108.

Before I saw her she had been treated for diabetes, and had taken considerable quantities of opium. She was still at service and had to undergo considerable fatigue. I continued the treatment until I obtained some of her urine. I found it acid, pale, containing a great quantity of fawn-coloured lithates, of specific gravity 1.026, and large crystals of oxalate of lime.

The urine examined was passed after breakfast, and two hours elapsed before the examination.

June 25th. I insisted upon her leaving her place for a time, ordered her a light mixed diet, slight cathartic, and treated her in the usual way.

July 10th. Was discharged well. The oxalate had disappeared, and the quantity of urates and the specific gravity had gradually fallen off. Her catamenia are still absent.

These three cases are of the kind most generally met with, yielding readily to treatment and affording another proof of the progress of scientific medicine. In these and all other cases of oxaluria I have found great mental prostration a constant symptom; it did, not however occur early in the progress of the disease, but succeeded upon a continuance of bodily lassitude and lumbar pain. The appetite was always variable,—sometimes good, at other times wanting, and more frequently ravenous and unsatisfactory. The lassitude and lumbar pain were constant and invariable symptoms, and should, especially when combined with any hypochondriacal symptoms, raise our suspicions of the presence of the oxalate of lime in the urine.

The only satisfactory method of detecting the presence of combinations of oxalic acid in the urine is by the use of the microscope; and as everybody has not a good defining achromatic instrument, it is as well to observe that a moderately-powerful chromatic microscope, such as were in fashion twenty years ago, will suffice to detect the peculiar octohedra. I have, when away from home, frequently been obliged to employ one of these usually inefficient instruments, but have found them answering my purpose. The urine destined for examination may be placed upon a slip of glass, or in a watch glass, and then heated, to dissolve any crystals of urate of ammonia; or the urine may be filtered through fine blotting paper, which retains the crystals of the oxalate. Distilled water is used to wash these off previously to their being submitted to examination. These are the methods recommended by Dr. Bird, and, I believe, by Dr. Venables.

(*To be continued.*)

SHORT NOTES ON THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

On Gleet.—A gleet signifies a discharge from the urethra, generally of a transparent or whitish colour, somewhat like serum, and it is not contagious. There are no particular characters by which a gleet can be distinguished from the chronic stages of gonorrhœa. The latter has apparently continued months, without producing in those who have been exposed to it any infection; whilst on the other hand, a mere lympid fluid has communicated gonorrhœa. In gleet, there may be a yellow, profuse, and very offensive discharge, without its being infectious.

The cause of gleet has been attributed to a laxity of the vessels of the urethra; but this opinion does not agree with a just notion of secretion; since gleet is not more likely to arise from this cause—that is, relaxation, than the secretion of the natural mucus of the urethra; and the vessels secreting this mucus are active, not passive.

Gleet has been described as the result of an increased mobility and sensibility of the parts; but if this were the case, the fluid should be as inordinate in quantity as the alteration is in quality. Venereal irritation may leave a præternatural irritability of the part; and it is curious to observe that a discharge which was once contagious, may become innoxious without any sensible change of its properties.

When gonorrhœa is attended with any induration of the urethra, the discharge is seldom cured till the induration is removed. The bichloride of mercury given for a few weeks will, in such a case, be found useful.

Urethral discharge from the metastasis of gout, where no morbid alteration existed in the part, having the same appearance as that in gonorrhœa and gleet, proves that the discharge arises from irritation. Some persons of gouty constitutions, have urethral discharge once or twice a year; and a regular fit of the gout always removes it. Priapism also often comes and goes under the same circumstances. Ague will sometimes carry off gleet, and as the former subsides the latter will probably return.

Some cases of gleet are attended with great uneasiness and spasm in the perineum. These symptoms are first to be subdued by leeches, purgatives, &c., and then the urethral discharge may be suppressed. In the treatment of gleet, the principal indication is to correct the irritable state of the urethra, which causes the disease; but there is no medicine which can specifically fulfil the indication.

Cold bathing, partial or general, cannot be depended on, and often does harm till the inflammatory symptoms have subsided; after which it will generally be found serviceable. Bark, zinc, iron, &c., are employed; but these are seldom of use in men. Balsams and turpentines in large doses will frequently succeed and frequently fail. The diacetate of lead with opium, has been given with no certain success. Alum will probably be of greater use. The tincture of cantharides will sometimes succeed where the terebinthinates have failed; thirty drops may be given three times a day, adding a drop to each dose till stranguary is brought on. Two or three drachms, or even six or seven drachms, of the tincture have been given in a day, without causing strangury; yet a single grain of the powder will sometimes produce the effect at once. [The lytta powder should always be given with great caution, as

* Continued from page 516.

it is very apt to produce severe gastric effects, which it may be very difficult to subdue.—Mr. Pearson seems to have been aware of this from what follows.]

Half a grain of the powder will be sufficient at first, and the dose should seldom exceed a grain. Blisters to the perineum sometimes do good; and so will, occasionally, hard riding, strong shocks of electricity, and the introductiou of a bougie. With regard to injections, all those kinds may be used which have been already recommended; but the misfortune is, that in giving up the injections the gleet will return, and continue till it wears itself out.

Affections of the Urinary Passages, or those Causes which interfere with the Natural Evacuation of the Urine.—These are of three kinds,—ischuria, dysuria, and enuresis. Ischuria signifies retention of urine, and may arise from causes in the bladder itself, or in the prostatic urethra.

When a patient labours under retention of urine, it may be ascertained by the length of time that has passed since any urine was voided, by intumescence of the hypogastric region, and by feeling a palpable fluctuation in the swelling; sometimes, however, the fluctuation is not very distinct, especially in corpulent persons. It may also be known by a round projecting body being felt on introducing the finger up the rectum. These symptoms are accompanied by painful and fruitless endeavours to pass the urine.

Cistitis.—When inflammation of the bladder is the cause, the distension of the viscus is always attended with most severe pain, and a considerable degree of symptomatic fever. If no relief be obtained in four or five days, mortification and death will ensue.

On being called to a case of this kind, the first thing to be done is to remove the inflammation, by taking blood from the arm; and a large quantity should be taken at once, so as to produce fainting, a result of the bleeding most likely to prove serviceable. It will also be proper to give purges and purgative glysters, so as to completely empty the bowels. Calomel is the best purge in such a case; warm bathing should be employed at the same time. After evacuating the system, opium will be found useful, given to the extent of a grain every hour till sleep is produced. This has caused such a relaxation of the vesical sphincter, and of the urethra, that the urine has flowed away involuntarily.

If there be time to use the above remedies, and no relief be obtained, it will be necessary to draw off the water with a catheter. During its introduction, no violence is to be used, as, by propelling the instrument with too much force, there is danger of injuring the urethra, making a false passage, or penetrating the walls of the rectum, which is by no means an uncommon accident.

An elastic-gum catheter is better than a metallic one, as it is not so apt to do violence to the parts; but it does not always succeed, from its want of firmness, even with a stilette. In every case it may be tried first, and if it does not succeed, a metallic one must be used.

It is of great consequence that the instrument be not introduced in a hurry, and that it have a proper degree of curvature; the common curve is far too great; but where there is enlargement of the prostate gland, the curve of course must be greater.

When there is much difficulty, it will be useful to withdraw the stilette a little as the instrument approaches the bladder, which will have the effect of elevating its point a little more, and thus enable it to pass over any projection of the prostate gland.

Sometimes the introduction of a fine bougie into the urethra, and suffering it to remain a minute or two, will remove the spasm, and relieve the bladder, where all attempts to introduce the catheter have failed.

But when inflammation of the bladder has caused the retention, and every effort to evacuate the urine by the above means has failed, the puncture of the bladder becomes indispensable.

Modes of Puncturing the Bladder.—The first mode is *by the urethra.* The patient having been placed in the same position as in lithotomy, a deep incision is to be made in the perineum, a little behind the bulb, and the fore-finger of the left hand being passed into the rectum to guide the instrument and guard the intestine, a trocar is to be pushed through the perineal opening into the bladder. The perforator is then to be withdrawn, and the canula suffered to remain till the cause of the retention is removed.

The second mode is above the symphisis pubis. The canula should be about two inches long, if it be shorter, there will be danger of the bladder slipping off; and if it be longer, there will be danger of its being bored through the coats of the bladder. The puncture should be made an inch or an inch and a half above the pubes; if higher, the bladder, in contracting, may probably slip from the canula, and if lower the instrument may make a passage through the bladder into the rectum. Mr. Sharpe directs that the canula should have two rings, through which tapes may be passed and secured around the pelvis. The orifice should be closed with a small peg of wood, instead of a cork, which often breaks and becomes troublesome; a piece of sponge also may be placed at the end of the canula, to absorb any urine which may flow through it.

If the bladder slip from the canula, or the canula from the bladder, it will be difficult to re-introduce it, in which case a common female catheter may be used, as it will be passed more readily.

The principal objection to this operation is, that in corpulent persons the bladder cannot easily be felt, there being a great depth of fat between it and the

integuments. When the patient is thin, and the bladder is felt high in the hypogastric region, the operation is safe and easy.

Instruments that remain in the bladder longer than eight or ten days become incrusted with calcareous matter, which is separated from the urine, they should therefore be removed every three or four days, for the purpose of cleansing them.

To prevent the difficulty of introducing the instrument again, some have recommended a double catheter, forgetting that the inner will require cleansing as well as the outer one.

The third method of puncturing the bladder is through the rectum. It was first practised in France by M. Fleurant, and in England afterwards by Dr. Hamilton, of Lynn Regis, and next to him by a Mr. Bentley, near Hull; since then it has been frequently performed in this country and generally with success.

The following is the mode of performing the operation:—The patient being placed as for lithotomy, two fingers are to be passed into the rectum, to the part where the distended bladder can be felt, and then a slightly curved canula, containing a trocar, with its point drawn a little within the distal orifice, is to be introduced by the left hand upon the fingers of the right, up to the point to be punctured, and when the end of the canula is felt pressing upon the tumour, the perforator is to be pushed forward into the bladder, and a sufficient length of the canula propelled with it.

After the bladder has been emptied, the canula should be kept in communication with the cavity of the bladder for forty-eight hours, to prevent the wound being healed by the first intention; but should the rectum be unable to bear the irritation of the canula, it must be withdrawn at once, as in all probability the urine continuing to flow through the wound, will prevent its being healed.

The urine generally continues to flow through the artificial passage till the urethra is made free, when it resumes its natural course, and the wound heals.

If there be preternatural enlargement of the prostate gland, or any excresence within the neck of the bladder, this method of puncture is impracticable; and when it can be performed, the puncture should be judiciously and carefully made, so as to avoid wounding the vesiculæ seminales and entrance of the ureters.

In females, the bladder has been generally punctured above the pubes, and the mode of performing the operation is exactly the same as in the male; during pregnancy, however, there is great danger of wounding the uterus, without great care, and in such a case it has been recommended to puncture the bladder through the vagina. [This method is now generally preferred.]

When the urine returns by the urethra, it is loaded with a yellow flocculent mucus, which is of no importance, and will go off in a few days. During the cystic inflammation, and the progress of the case, the greatest attention must be paid to diet.

Another cause of ischuria vesicalis is a loss of tone of the muscular coat of the bladder, so that it cannot contract upon and expel the urine. The bladder is a viscus of a compound character. Its body is elastic, dilating to receive the urine, and contracting to expel it; whilst the fibres around its neck form a sphincter muscle to give it a containing power. Now, whatever tends to diminish the expelling power of the bladder becomes the cause of retention of urine.

This loss of power may take place from various causes. The first and most common is, a disregard to the stimulus of the urine, when a call is felt to evacuate it; for if the urine be detained, the desire of voiding it is lost for a time; and if this disregard to the calls of nature become habitual, the bladder accommodates itself to hold a larger quantity than is natural, and loses proportionately its susceptibility.

The inconvenience of this dilatation might not be felt till the patient is advanced in years, or has fallen into some unusual irregularity, when the body of the bladder ceases to be able to expel the urine.

The common quantity, which the bladder in a natural state contains, is from one pint to a pint and a half; but from habit it may become so dilated as to contain considerably more than a gallon. The bladder is said to be capable of containing all the urine that is secreted in twenty-four hours, and the average has been stated at four pints three fluid ounces.

As the bladder becomes more and more distended the patient feels unable to void the urine; or the attempt is made with great pain; the bladder having lost its expelling power.

Even when the catheter is being used, the bladder does not always regain its power at once, but requires a repetition of its use for some time. In these cases the bladder dilates gently and gradually, and without much, if any pain, till a tumour is felt rising, as the distension continues, in the hypogastric region, and it sometimes reaches as high as the umbilicus.

Sometimes after the retention has been long neglected, there will be an involuntary discharge of urine, but without lessening the size of the tumour or giving any relief, the bladder not being at all reduced by it. The quantity of urine escaping is only equal to that which is secreted and distilled into an already-distended receptacle, which, in fact, now becomes an overflowing bladder.

In such a case the patient will often declare there is nothing the matter with his bladder and that he makes the usual quantity of water. [The impression of the patient sometimes is, that instead of making too little he makes too much.] But if with these symptoms a tumour is felt above the pubes, the catheter is to be at once introduced.

The first and almost only indication is to draw off

the urine; and as there may be no morbid alteration of structure either in the urethra or neck of the bladder it will be done with the greatest facility till the cure is effected. The bowels are to be kept open at the same time.

The principle by which the surgeon is to be guided with regard to the frequency of passing the catheter is, that the bladder must never be suffered to be abormally distended. The usual times recommended for drawing off the urine are night and morning; but in some cases it will be necessary to do so three times a day or oftener.

The principal objection to the frequent introduction of the catheter is the irritation produced in the urethra; and when the catheter produces this effect, it has been proposed to obviate it by suffering a gum-catheter to remain in the bladder properly secured, to prevent its displacement. When the patient is confined to his bed, this might easily be done, but few can walk about with it; and if they can do so, the advantage of horse exercise must necessarily be lost; when, however, there is no hope of restoring the expelling power of the bladder, the plan of wearing a catheter will be very useful.

During the first five days of drawing it off, the urine will probably flow through the catheter very slowly, and the first symptom of amendment will be the expulsion of the urine with greater force, and a perceptible action on the instrument; and sometimes also there will be considerable pain felt on the expulsion of the last drops of urine, from the bladder contracting upon the catheter.

The bladder may recover itself in a week or two; sometimes from eight to fourteen weeks are required. But when there is no amendment observed in four or five months, a cure can hardly be expected.

Sometimes there is an intermission of the complaint for a day or two, when it returns, and this variableness may occur to the patient several times during the cure.

The diet should be temperate and nutritious, and if the person has been accustomed to wine it should not be absolutely forbidden. Exercise on horseback may be taken with advantage; cold bathing, or the local application of cold, may be used. Blisters may be applied to the sacrum, and friction with a strong solution of camphor upon the groins and region of the bladder may be also of service.

Bark and preparations of iron may be administered when the system is weak, but it is uncertain whether they in any degree accelerate the cure. Electricity will not be found of great use, and it occasionally produces a bloody discharge. These remedies, however, are not to be so much relied upon as the catheter, which must be continued till the bladder can empty itself by its own natural efforts.

Temporary retention of urine, where there has been no previous habit of retaining the urine, will be sometimes speedily relieved by applying cold water to the penis and perineum, to the legs and feet, and by endeavouring to void the urine in a cold situation. Towards the end of the cure bougies may be advantageously used, which do good probably by stimulating the neck of the bladder.

Retention may also be occasioned by common paralysis of the bladder, the sphincter remaining in a natural state. This is an uncommon cause of retention, though the symptoms are nearly the same as in the preceding kind. There is usually a slight degree of uneasiness about the neck of the bladder, and the propelling power is below the natural standard, from a defect of nervous energy.

The catheter must be introduced as recommended in the former case; and as the urine will not always flow through it, from the muscular coat of the bladder not possessing any contractile power, it is necessary to press upon the abdomen to evacuate the fluid.

Friction, with camphor and blisters, might be of service, though the grounds of hope are less evident in this species of the disease than in the former. The patient may remain ten minutes in a bath heated to 110° with benefit; bark, and the cautious use of the powder of cantharides, three times a day, have been also found benefical. By these means the power of the bladder will probably be in some degree restored.

(To be continued.)

ON THE EFFICACY OF THE SULPHATE OF BEBEERINE IN STRUMOUS OPHTHALMIA.

By Henry Llewellyn Williams, M.D., Edin., M.R.C.S.E., Surgeon to the Beverley Dispensary, Fellow of the Botanical Society of Edinburgh, &c.&c.

Scrofulous affections are most certainly on the increase; nor is this so much to be wondered at, when we take into consideration the existence of many things likely to favour and promote such complaints,—such as an enlarged population, without a proportionate increased means of support, and the close unhealthy houses in which the children of the poor are huddled together in a state of abject filth. It is not, however, the object of this paper to enter upon a discussion of the cause of affections of this nature being more frequent than they formerly were; suffice it to say, such is the case.

Of scrofulous affections, none are more frequent and troublesome to contend with than strumous ophthalmia, occurring generally between the periods of infancy and puberty. In our large towns it is so common an affection, that of ten cases of inflammation of the eye, eight will be of this kind. It is known by several different names: thus it has been termed pustular, from the appearance of a number of minute pustules upon the surface of the organ; it has also by Dr. Mackenzie been called phlyctenular ophthalmia, as he believed it to affect the conjunctiva not so much as a mucous

membrane as a continuation of the skin. It is a disease, as its name implies, intimately connected with the scrofulous constitution, the external marks of which every medical man is acquainted with. The fair complexion, the thin integument, the distinctness with which the ramifications of the cutaneous veins are seen, the short and thickened upper lip, the red or sandy hair, are some of the most prominent features of this state of constitution.

Scrofulous ophthalmia is most prevalent from the time of weaning to about the age of eight. There is usually only *slight* redness of the conjunctiva, sometimes confined to that lining the lids, occasionally extending to the covering of the globe. There is always great intolerance of light; little prominences or pustules form on the surface of the conjunctiva generally; a few vessels collected into little bundles are seen proceeding from the same point of the circumference,—more frequently from the angles of the eye than from any other point,—towards the cornea, and at their termination, the small elevations which have obtained the name of pustules, are discernible. They are more frequent at the junction between the sclerotic and the cornea, or near that line. These pustules may become absorbed, and leave behind a temporary white speck; often they break, and form ulcers. When these ulcers are situated beyond the cornea, they are of little consequence, but when on the cornea, they call for more attention, as danger may result in two ways,—either by penetration of the cornea, permitting the escape of the aqueous humour and prolapsus iridis; or after cicatrization has taken place, a permanent white spot may remain, which will interfere more or less with the patient's vision, according to its size. I may be permitted to take this opportunity of cautioning practitioners against the indiscriminate use of acetate of lead, as a collyrium in this affection, for I have seen more cases than one where the ulcer has become the seat of a white deposit of sulphate of lead, from the employment of this wash, and which, of course, results in permanent opacity. The great intolerance of light is a very prominent symptom of this disease, and sometimes it is really the only symptom that manifests itself; the child will skulk all day in dark corners, so great is its dread of the approach of light. If brought to the window, he holds down his head, and presses his hands or arms before his eyes. Children affected with this disease carry it legibly written in their physiognomy. The child's brow is knit and contracted, and those muscles of the face are instinctively called into action, which tend to exclude the light without quite shutting out the perception of objects. When it is attempted to open the eye, it is accompanied by profuse lachrymation. The tears pass partly over the skin, which they sometimes inflame and excoriate; frequently pustules arise, and produce a discharge, which, forming a crust on the cheek, often extends to the forehead and temples. This *crustea lactea* is very characteristic of the scrofulous habit.

The treatment hitherto found of the greatest benefit, after the free evacuation of the alimentary canal, has been counter-irritation, combined with tonics. Leeches in a very acute attack may be sometimes necessary; but generally by reducing the system, when it will not bear reduction, they have tended rather to retard than promote recovery.

Dr. Mackenzie has strongly recommended the use of quinine as the best tonic, in which opinion he is supported by Mr. Lawrence, who says he has frequently seen it act "quite like a charm;" in these cases no one will therefore question the utility of tonics. It is my purpose in this communication to draw the attention of the profession to the superiority of the sulphate of bebeerine* to the sulphate of quinine, not only on account of the moderate price of this drug as compared with quinine, which is in itself a strong recommendation, especially in dispensary practice, but also, because, according to the testimony of Dr. Douglas Maclagan and others, it is better adapted to some constitutions and affections than quinine, not being so liable to excite the circulation or affect the nervous system. The following case, one out of many that I have had under my care, will illustrate its beneficial effects:—

STRUMOUS OPHTHALMIA TREATED BY THE SULPHATE OF BEBEERINE; CURE.

J. L., eight years of age, was seen on the 17th of July, the child presented all the characteristic features of the strumous diathesis. He was much emaciated. His mother informed me he had a similar attack two years previously, since which time there has been some intolerance of light. The conjunctiva lining the lids was very vascular; the margin of the cornea of the right eye presented a number of minute phlyctenulæ. He was ordered a purge with calomel and rhubarb, a blister behind the ear, and warm water to the eye.

20th. The appearance of the eye much the same; the other becoming affected. To repeat the purge, and take two grains of sulphate of bebeerine night and morning. Strict attention to his diet insisted on.

23rd. Blister behind the left ear, as the corresponding eye presented two or three well-marked ulcers on the cornea. To continue the bebeerine.

27th. A lotion was ordered with two grains of sulphate of alum to the ounce, which was alternated with the sulphate of zinc. He continued to take the bebeerine upwards of three weeks; after that time, he was discharged cured, the ulcers being healed, and the intolerance of light quite abated.

* For an account of the medicinal properties of bebeerine, see Dr. Douglas Maclagan's papers on the subject, in the "Edinburgh Medical and Surgical Journal," April, 1845; also "Monthly Journal of Medical Science," August, 1843.

CASES FROM PRIVATE PRACTICE.*

By JOHN RICHARD WARDELL, M.D., Edin.

Late President of the Royal Physical and Hunterian Medical Societies, Assistant Pathologist in the Royal Infirmary, Edinburgh, &c. &c.

CASE IX.—EXHUMATION IN SUSPECTED POISONING.

Post-mortem examination. Body much emaciated, and muscles feel soft and flabby to the touch. Considerable livid blueness over abdomen, which is most intense

* Continued from page 546.

over the hypochondria, and extends up to the thorax more on the left than on the right side. Slight congested appearance, from gravitation, on posterior aspect of thorax. Between the right trochanter and superior anterior spinous process of the ilium, is a large soft tumour, about the size of an orange, and on the anterior part of this tumour is a dark roseate irregular eschar, measuring three inches from above downwards, and two and a half in breadth. On opening this tumour, four ounces of rusty-streaked pus escaped. At the flexure of the right ankle is a cracked irregular eschar, of about the size of a shilling; there is also an excoriation on the left hip of equal dimensions. Corresponding with the prominent part of the sacrum is a ragged sloughing ulcer, somewhat less than a half-crown piece. *Head:*—On reflecting back the scalp, a little above the supra-orbital region, is observed a congested patch, evidently the result of contusion, measuring an inch and a half in diameter. Removing the calvarium, the surface of the brain looks natural; cutting into the encephaloid mass, and exposing the centurm ovale, no bloody puncta are manifest, nor upon subsections of the organ can any anormal characteristics be discovered. Feels of ordinary consistency and the cortical substance extends as far into the medullary matter as is generally observed in healthy subjects. No serum in the ventricles. On carefully examining the base of the skull, the right posterior tubercle of the sella turcica is much more acuminated than ordinary, and on placing the finger upon it, its apex feels sharper than natural. *Thorax*:—Removing the sternum, the lungs are not quite so prominent as natural, and their colour is anormally pinkish; little or no decomposition has commenced. Left lung adherent throughout to the pleura costalis by organized bands of lymph; on its posterior aspect is to be noticed some degree of congestion, and especially inferiorally. On the serous covering corresponding with this, is a transparent gelatinous exudation, which is easily broken down beneath the fingers. Several sections made in the organ show morbid redness, the colour in some parts, particularly in congested portions, is of a light vermillion hue. Crepitation, though less distinct in some parts, is nowhere entirely lost, and the organ lightly floats in water. Right lung also attached to the pleural lining of the thorax by morbid adhesions, but not so extensively as the left lung. On being removed, physical characters pretty nearly resemble those described of the left, but congestion not so marked and bright; redness not quite so distinct; is generally crepitant. No tubercular deposit seen in any part of either organ. *Heart:*—This organ is in every respect healthy, all its valves seeming competent to their functions. Pericardium contained four drachms of serous fluid. On excising a portion of the œsophagus from the middle of its course, the mucous membrane presents its wonted characteristics. No vascularity of any importance. *Abdomen*:—Liver normal in all its appearances; spleen small, but parenchymatous structure unaltered. Stomach externally manifests its wonted characteristics; in the cavity are contained two ounces of matter of semi-liquid consistence; vascularity of the mucous membrane not more than is often seen in the organ, where no disease of it has existed. In a few places adherent to its rugæ are a few small black depositions, which seem of a vegetable nature; beneath these spots, on being lightly scraped off by means of a scalpel, not the least degree of vascularity can be detected, and they seem to have excited no action whatever on the surface; they are insipid to the taste. On the lining membrane of the duodenum are a few slightly-developed arborescent patches; no ulceration nor excoriation; jejunum natural. Towards the lower extremity of the ileum, for ten or a dozen inches, there was considerable arboriform vascularity; mucous covering tolerably firm to the touch. On one part of the caput cæcum coli is some injection, but no ulceration. The arch of the colon presents no morbid appearance; signoid flexure much congested and vascular. Throughout the internal surface of the rectum is discoverable much ramified injection, extending about nine inches, and here and there are to be seen small but well defined ulcers. Kidneys in every respect healthy. The uterus is particularly small, and on a longitudinal section being made, its substance is somewhat cartilaginous.

Tests used to the Contents of the Stomach.—1. Solution of ammoniaco-nitrate of silver gives a milky colour.—2. Solution of ammoniaco-sulphate of copper throws down a cloudy white.—3. Lime-water gives no precipitate.—4. The hydriodate of potash exerts no sensible effect.

The manner in which the above tests were used was by adding a portion of the contents of the organ to distilled water in small test tubes. The small black patches were carefully tested by the above, but remained unchanged.

Remarks.—Casual circumstances sometimes so occur as to create surmises, and give a colouring to opinions that would otherwise have been deemed most improable, or never been entertained; and so it was relative to the case calling forth these brief observations:—A person, residing in a lonely part of the country, chanced in the course of a few years, to lose three inmates of his house, all dying suddenly. First, a former wife, next a housekeeper, and, lastly, his daughter, who was at the time of her decease, and had been for several years previousiy, insane. No medical man had attended her, although it was proved she had been in a failing state for some time before she died. Through an irregularity no inquest was held prior to her interment, and certain (when investigated,) satisfactory circumstances rendered it necessary that her funeral should take place at an earlier period than was customary. A fortnight subsequently a report became prevalent in the district that she had not died from natural causes; information consequently being given to the Coroner, he, in discharge of his duty, issued a warrant for the exhumation and examination of the body, and that gentleman employed me to make the *post-mortem* inspection; and as there appeared, on a review, to be some points of interest associated with the case, both pathologically and medico-legally, I have thus been induced to insert it here.

Great are the responsibilities in being summoned to officiate in an instance like the present; and highly important was it that a correct opinion might be formed of the case, because reputation, nay, more, the most weighty dependencies, were based upon a right decision. The Coroner, very judiciously, ordered a careful examination of the body before entering into a detail of evidential enquiry, and thus the medical opinion as to the cause of death was more likely to be unaffected by preconception and prejudice. It has, in an earlier paper of this series, been observed, that the medical man when engaged to give his opinion in medico-legal cases, has nothing whatever to do with the statements deposed by witnesses; he is employed to give his professional opinion as to the extent of injury, or the cause of death, and in this decision it is highly desirable that his mind be unbiassed by any preconcerted notions from vague reports, or hearsay suppositions. In all country districts, prejudices are deep-rooted; and there is much repulsive feeling towards *post-mortem* examinations, even amongst those who assume to be of the educated and better classes. In this case it would have been absurd to merely exhume the body without a dissection, and the Coroner very properly insisted upon definite depositions being made relative to the morbid appearances to be discovered in the viscera.

On reference to the foregoing details of the inspection, it is mentioned that the body was in a state of considerable emaciation; and that above the right trochanter was a large abscess, which, from the consideration that similar collections had formed spontaneously in other parts of the body under the integuments, was evidently of a scrofulous character.* On exposing the brain, the vessels proper to its structure, and the membranes covering it, were not at all engorged; there was none of that venoid appearance which is observed where narcotism has preceded death, and which I have before described under the avowed poisoning by laudanum. There were no bloody puncta on making repeated sections of its substance; no anormal quantity of serosity infiltrated into its ventricular cavities. It has been stated, I may here observe, by certain morbid anatomists, of the insane, that enlargement of the clinoid processes, producing pressure at the base of the brain, has caused insanity;† and certainly in this case the posterior processes were decidedly more acuminated than ordinary; but whether it would be right to subscribe to the asserted opinion, is very dubious, until more irrefragable data confirmatory of its truth have been amassed. From the morbid characters presented by the lungs, it is impossible to dispute the existence of inflammatory action at the time of death, as the parenchymatous structure bore the obvious traces of pneumonia in its first stage; yet such was not of itself sufficient to cause (although, in a patient so debilitated it might have expedited,) death. On the serous surface of the left lung, were recent fibrous depositions, and the natural crepitancy was diminished, which remarks also apply to the right lung, but in a less degree. The congestion noticed at the base of these organs, was more the result of gravita-

* During the time of my official connection with the Edinburgh hospitals, some cases came under my notice in a certain degree analagous to the one in question,—that is where scrofula and insanity are combined One man had several scrofulous abscesses in different parts of the body, but especially in the subcutaneous cellular tissue forming what surgeons denominate, *cold abscesses*. He was of phthisical tendency, and gradually lost his reason. On inspection there was discovered a greenish yellow deposition of pus at the base of the brain, and the surrounding parts of the organ were decidedly softened, more especially the medullary part. Previous to the examination of the brain of this girl, I rather suspected a similar condition, which, however, as the report shews, was not the case.

† When recently at the Mary-le-Bone Infirmary, where a number of insane patients at all times form a portion of the inmates of that establishment, and where pathological investigations are diligently pursued, the resident physician, Dr. Allen, informed me that in a very considerable number of *post-mortems* which they had on the bodies of the insane, in a very large majority of the inspections, physical causes were decidedly obvious. The morbid conditions most frequently found, were præternatural vascularity, softening, much serosity, induration, thickening of the membranes, atrophy, anormal developments, and osseous prominences. Esquirol and some other writers have asserted, that instances not unfrequently occur, where no lesion exists. In such cases would not microscopical examination often shew positive structural change, when not at all suspected? My friend Dr. Bennett, now Professor of the Institutes of Medicine in the Edinburgh University, has for years paid considerable attention to disease of the nervous centres, and I recollect some instances in which that gentleman detected organic change in the ultimate structure of the brain, when the symptoms were accountable by no other appearances, and when, indeed, others gave it in opinion that the encephalic mass was healthy. Dr. Bennett used to say, what the telescope is to the astronomer the microscope is to the scientific physician, and most undoubtedly our notions respecting the ultimate cause of numerous abscesses, by its use, have become wonderfully more correct. Morgagni, Esquirol, Pinel, Calmeil, Lallemand, Georget, Bouillaud, Prichard, Conolly, and others, have been amongst the chief investigators of the lesions common to this disease, and the labours of these writers have tended considerably to elucidate a subject once so ill-understood. Dr. Allen said that he did not find the diminution of the cortical substance, as spoken of by many authorities, who, in accordance with physiological reasonings, wish to shew that loss of grey matter would be followed by loss of sense. Whether the grey matter be the grand seat of reason or not, is still doubtful; and this case and certain others that have come under my own notice, do not bear out that theory. Violent attacks of fever sometimes leave the mind affected; hence that irascibility which follows febrile diseases, which is, doubtless dependent upon physical causes, as vascularity, or perhaps change in the granules or tubercle. I yesterday saw in consultation, a young lady, who had long suffered from disease of the cerebro-spinal system; she attributed her illness to previous attacks of typhus fever, which she had had to the fourth time. From a detailed history of her case, and a general review of existent symptoms, I fully concurred with the gentleman under whose care she now is, that there was softening, at least such condition was exceedingly probable. Three or four years ago I attended a smith, whose occupation had been to weld iron in a large manufactory, where the immense fires exposed the mechanics to a very high temperature. The great heat, by præternaturally stimulating the brain, produced total blindness, and gradual fatuity.

tion than from obstructed circulation. In all cases we should distinguish between diseased congestion and that state which is produced by the gravitating of the fluid, and which is always most distinct when the patient has been lying on the back. Those at all conversant with morbid appearances, can readily distinguish between the two. The heart, œsophagus, (the mucous membrane of which organ it is always desirable to carefully examine in cases of this description, as irritant agents invariably produce greater or less excoriation,) liver, spleen, stomach, jejunum, and kidneys, were found natural. In the course of the ileum, at the caput cæcum coli, and sigmoid flexure, a præternatural state of vascularity existed; and the rectum was not only in the same state at several places on its mucous membrane, but there were also distinct points of ulceration. Now, these appearances might, *primâ facie*, have been considered as the result of some irritant agent applied to the digestive surface; but when it is reflected that the patient for some weeks was reported to have had a bowel complaint, and this of a dysenteric character,—that the morbid conditions were not of a recent, but of a chronic, nature,—and, above all, that the stomach was found healthy, it became highly probable that such were the result of spontaneous disease, and not from irritant poisons. Whenever irritants have been swallowed, the mucous membrane of the œsophagus and the stomach are sure to be affected, and there most especially the lesions are discoverable. There is diffused inflammatory redness; the mucous membrane acquires a reticulated vascularity, with softening, gangrene, and irritable obstruction of one or more of the tissues. In the lower bowels the same description of lesions is discernible, though in a less degree than what takes place in the higher portions of the canal. Chronic vascularity of the mucous surface differs in certain respects, and by these we may decide between that which is recent and that which has for some time existed. In the one there is diffused redness as well as tortuosity of the vascular branches, resulting of course from capillary distension; but in the chronic form the inter-arborescent spaces have acquired their former colour, dependent upon the capillaries proper to such parts, having contracted to their former calibre. The smaller vessels of a part more readily resume their former condition than the larger, because it is with the capillaries that the resolution or salutary change first commences. When for some time there has existed obstruction in these minute vessels, the smaller branches of the arterial and venous systems which arise from them are obstructed also; hence their calibre is increased, and thus results that state of preternatural distension which we term vascularity, and as the capillaries soon resume their natural condition, these branches remain in a state of tonic fulness when the inflammatory blood has disappeared. It is on this theory that the nitrate of silver, and some other remedies have their beneficial effects; they stimulate the tunics of the vessels, which from impaction of their contents had lost their natural contractile functions, and thus by astringing these vessels a cure is effected. Reasoning from these considerations, taking into account the above-mentioned facts,—viz., the existence of a dysenteric affection,—the considerable emaciation,—the inflammation of the lungs,—that the patient was insane, and consequently masking symptoms that might otherwise have been more prominently manifested,—that the stomach shewed none of those traces common in irritant, nor the brain the characters so frequent in narcotic, poisoning, I gave it as my opinion that the patient had sunk under natural causes.

The statements of the various witnesses examined at the inquest fully confirmed the conclusion advanced in the medical evidence. The deceased had always partaken of the same food as her parents; for some time she had gradually lost flesh, had become more wan and emaciated in appearance, but as she was so totally devoid of reason, any indisposition could only be judged of by her looks. Some days before her death they considered her not so well,—the diarrhœa was in particular mentioned, and they had consulted a practitioner a month previous to her death, respecting this affection, but that gentleman did not see her, and ordered them to give her a few drops of laudanum, under which remedy little or no benefit accrued. The day previous to her death she had an urgent thirst, which might have been anticipated where active inflammation was going on. The mother, on taking her breakfast to her in bed, saw that she was then very ill, she became rapidly more enfeebled, and soon expired. The jurors, on a deliberate review of all the circumstances, and the facts detailed in medical evidence, without any hesitation returned a verdict of death from natural causes. Had an inquest taken place previous to her interment, which ought to have been the case, but from some mistake or irregularity was omitted, no *post-mortem* examination would have been required, and the friends, who for a time were much distressed at the painful imputation, would thus have been saved a considerable amount of mental suffering.

(To be continued.)

ON TURNING,

AS AN ALTERNATIVE FOR CRANIOTOMY AND THE LONG FORCEPS.

By Robert Collins, M.D., Dublin.

To Professor Simpson, &c., &c., &c., Edinburgh.

My Dear Sir,—

I beg to thank you for forwarding me the proof sheet of your "Memoir on Turning, as an alternative for Craniotomy and the Long Forceps, in Deformity of the Brim of the Pelvis." You are so good as to state in the letter which accompanied the first part

of your memoir, that, "If it contains any errors of statement I shall feel greatly obliged by your pointing them out that I may correct them."

It gives me pleasure to comply with your request, and I shall feel obliged by your publishing my letter as an appendix to your memoir.

The first statement I shall notice, is the *partial*, and, *consequently*, *erroneous* calculations you have given from my work; withholding the *total mortality*, as well as the *cause* of the fatal result, in *every case* of protracted labour met with, out of the vast number of sixteen thousand six hundred and fifty-four births, minutely recorded by me. Surely this is a great omission on your part; and thus, as you so justly condemn in others at page 9,* "you have drawn your deductions, not from the *whole* of the practice, but from *parts* only; you have not reckoned upon the certain results of the *general* collection of facts, but depended upon the fallacious results of isolated and individual instances." Again, you well remark, "the medical mind has ever been too apt to recollect and found upon those facts only which are in favour of any preconceived opinion or opinions it may chance to have adopted; and the causes of failure are too often forgotten amid the more agreeable remembrance of the cases of success," "It is on this account that the numerical method of reasoning and investigation, by obliging us to count up *all* our cases and *all* our results, whether good or bad,—whether instances of recovery or instances of death,—is no doubt destined to revolutionize, in a great degree, our modes of inquiry, particularly in surgery and midwifery, by imparting infinitely more precision and certainty to our present deductions and precepts where they are true, and shewing us in language that cannot be misunderstood, the erroneousness of our doctrine where they are not true."

In these sentiments I candidly agree; and the new era which my "Practical Treatise" has established in reporting the results of obstetrical practice throughout Europe, affords me extreme satisfaction. No report that is not *minute* can now command the attention of the profession; and where *all cases* and *all results* are faithfully recorded, mere extracts taken from such registries, can have no weight with those who are competent to judge for themselves.

The various errors you have fallen into by founding your doctrines upon *partial* data, and thus totally obliterating what is really most instructive in the *general* results, should not, I think, have occurred with the ample details I had furnished, and unquestionably not without printing what has been recorded as diametrically opposed to your conclusions. You extract from my work, that during the seven years I had charge of the Dublin Lying-in Hospital 16,414 woman were delivered in it; and of those 164 died, or 1 in every 100; and this you have followed up by a table, which you think proves that the deaths are increased in proportion to the duration of the labour, viz., where the duration of labour was within 1 hour, one woman in 322 died; from 2 to 3 hours, one in 231; from 4 to 6 hours, one in 134; from 7 to 12, one in 80; from 13 to 24, one in 26; from 25 to 36, one in 17; above 36 hours one in 6.

Why were these *obscure* calculations given, and the following highly important general results, and *cause* of death, in ALL CASES where the patient was more than TWENTY HOURS in labour withheld?

It is clearly stated by me that there were *forty-two* in number out of 16,414; or in the proportion of 1 in 391; and of the forty-two women who died, where the labour was above 20 hours, *one-third* of the children were born alive,—of the forty-two, *three* died of typhus fever; *nine* of puerperal fever; *one* of stricture of the intestine, with effusion into the thorax; *three* where the placenta was retained; *two* of convulsions; *one* of abdominal inflammation previous to labour; *nine* of rupture of the uterus; *one* of inflammation of the intestines, with pus in the uterine sinuses; *three* of anomalous disease; *one* of diffuse cellular inflammation; *six* of inflammation &c., subsequent to difficult labour; *one* of ulceration and sloughing of the vagina; *one* of disease of the lungs and hæmorrhage; and *one* of abdominal abscess.

Where we see from the simple statement given, that only forty-two died who were even above *twenty* hours in labour, and at the same time *look to the cause of death*; the fallacy of *extracts* in support of fancied realities is apparent.

Why, I would again ask, is my table not given which shews the *cause* of death in all cases in the hospital, and proves that 97 of the 164 deaths arose from causes *not* the *results* of childbirth? Considerably above ONE-THIRD of the entire mortality during my Mastership, occurred from *puerperal fever* during the first three years. That this very intractable disease is not the result of *protracted* labour, as you erroneously state, is notorious to those who have had opportunities of observing it, and is fully proved in my report, the total number of cases being eighty-eight; 71 of which were delivered within 12 hours, and 80 within 24 hours. If we were *only* to deduct the deaths from this fatal disease, which may be considered accidental, the *entire* mortality for seven years would then be less than *one* in *one hundred and fifty-six*. And why is it not stated that for the *four* last years of my residence in the hospital *after puerperal fever disappeared*, during which period the very great number TEN THOUSAND SEVEN HUNDRED and EIGHTY-FIVE deliveries occurred, *fifty-eight* only died, or in the proportion of *one* in ONE HUNDRED and EIGHTY-SIX?

The annals of medicine afford no even distant approach to this favourable, and I will add happy result, in an equal number of a similar class of females.

It is clear to me, even overlooking the friendship you have at all times proffered to me, common justice demands a full acknowledgement of this *vitally* important practical test, particularly when you venture to condemn the practice of one who has had so much greater experience than yourself. When you have had similar opportunities of acquiring practical knowledge, and are enabled by a *different* mode of treatment, to publish *happier* results for the benefit of your professional brethren and the public, your opinions will then deservedly be entitled to that just respect, which the promulgation of improvements, founded upon practical experience, must ever command. I must, however, with the greatest respect, both for yourself and your professional talents, protest against the authenticity of purely theoretical opinions, given with so much confidence by a junior member of the profession, who has not yet had time nor opportunity to mature his judgment.

The evil deeds which your theoretical doctrine of turning is calculated to give rise to, among junior practitioners, strongly suggested to me what I have stated, and which, be assured, is done in good part.

* *Provincial Journal*, February 9th, 1848, p. 58.

Your proposal is to substitute delivery of the child by turning, instead of lessening the child's head, in the most laborious labours, where there is extreme difficulty in the birth, owing to *deformity* in the brim of the pelvis. (I do not remark upon the long forceps, as I have no pretensions to do do so from practical knowledge.)

This is unquestionably a dangerous doctrine, more especially when we consider the great facilities which now exist for throwing the patient into a state of insensibility, which deprives her of the power of either expressing or feeling, the grievous injuries she may sustain from the most barbarous efforts of the unskilled practitioner, the after-consequences of which must, in a great proportion of cases, be calamitous.

That a degree of force totally inconsistent with sound practical knowledge, must be used, (after the very hazardous operation of turning is effected,) to get the child through a deformed pelvis, where in very many instances, even after the head is lessened, great difficulty is experienced, is obvious; and where such disproportion between the child and the pelvis exists, it is equally obvious the child cannot pass alive. Need I state to any physician of practical experience, the awful mortality which must inevitably occur to the mothers, when delivery is effected by such measures, compared with what I have so fully recorded of the practice you propose to alter.

Of 16,654 births in the hospital, delivery was effected in 79 by lessening the head, on account of *extreme* difficulty in the labour; or where the child was *dead*, and interference desirable, owing to the state of the mother; in six of the 79, delivery with the forceps was attempted, but no force consistent with safety could accomplish it. *Fifteen* only of the 79 women died, and in *none* of the 15 was death caused by any injury sustained in the actual delivery. The proportion of such deliveries, as I have fully stated, is greatly increased in hospital, by the same patient returning *two*, *three*, or even *more* times, in whom, from deformity or other circumstances, such mode of delivery is unavoidable. Another cause which *greatly* increases the proportion, is the *frequent* admission of patients after having been *two*, *three*, or *four* days in labour, and as the record of the cases shews, most of whom had been grossly mismanaged. Of 106 cases where the children were *still-born*, and the labour severe, nearly *one-half* were of this description.

It is a remarkable fact, that of the examples given by me, at page 487 of my "Practical Treatise," of *repeated* delivery of the same patient by the crotchet, but *one* woman died, thus satisfactorily proving, that where *death* succeeds this operation, the fatal result is not dependent on the mode of delivery, but upon the circumstances demanding such interference.

No theoretical reasoning, nor any other argument, without the *test* of *practical experience*, could for one instant cause me to listen to a statement to the effect, that if the children *had been turned* in the seventy-nine most trying and critical cases I met with, the results would have been more favourable; nay, I shudder at the thought.

What *test* could we have to place in opposition to what I call the *astounding practical fact*, that out of ALL the PROTRACTED, LABORIOUS, and TRULY DIFFICULT labours, where *delivery* was *effected* by the crotchet, in the unprecedented number reported, of sixteen thousand six hundred and fifty-four births, only *fifteen* proved fatal? Why is this simple and *overwhelming truth* not stated by you, simultaneously with the theoretical data you have given to support the statement you have made, that where the labour exceeded forty-eight hours, one patient in *three* died? Why did you not likewise state that only *eleven* patients died who were above forty-eight hours in labour out of the 16,414? Was it not imperative upon you to do so, as from your PROPORTIONAL extracts you have left your readers in total *ignorance*; for instead of the deaths being the *marvellously* small number of fifteen out of 16,654 births, your observations are of so truly dismal and feeling a character, that those who had not the clear statement I had given on the subject, which you had before you in my work, must unquestionably conclude the mortality from PROTRACTED labours, in which the crotchet was used, *frightful* indeed. I have little doubt, however, most practical physicians will agree with me, that the simple truths here stated remove the visionary gloom cast over your words.

I have still further given accurately the CAUSE of death in each of the fifteen women who died, from which it appears that out of the fifteen, *five* died from the effects of labour *previous* to *admission*, and are therefore not justly to be reckoned in the hospital practice; *five* from causes not the result of *protracted* labour, and two from the effects of *hæmorrhage*, where *the hand had been passed into the uterus*; so that it is *thereby demonstrated*, that in the *total* number of the most trying and hazardously-protracted labours met with in the *vast* number of 16,654 births, we have, I fearlessly designate it, the INCREDIBLE MORTALITY of THREE patients, and this under the treatment which you fancy you could improve, but in support of which improvement you have so little practical experience of your own to submit to the profession.

I have stated in my introductory observations on tedious and difficult labours, that there is no subject connected with the practice of midwifery so difficult to acquire a sound knowledge of, as the treatment of tedious and difficult labours; it is one of the most vital importance, and, in the most marked manner, distinguishes the experienced, from the inexperienced, practitioner. This information can only be obtained by diligent and persevering attendance at the patients' bedside; all other sources are comparatively worthless, and when not conjoined with practical experience, dangerous. I think it necessary to repeat the above declaration, as from the opinions you express, your readers might hastily conclude that I had no knowledge whatever of the danger of protracted labour, whereas there is no subject has caused me greater anxiety, or occupied my thoughts more.

My statements have invariably been made strictly in condemnation of *rash* and *hasty* measures, in order to prove, that where the patient is properly treated during the progress of labour, the *mortality* from the effects of *protracted labour* is strikingly small; and I do not think it possible to submit facts more unquestionable for the satisfaction of my professional brethren than I have done. Even supposing the entire fifteen women who died after delivery with the crotchet, to have died from the effects of protracted labour, this would only amount to the *one-eleventh* part of the mortality from *other* causes; but as I have shown that only *three* of the number can fairly be so attributed, the proportional mortality is reduced to one in fifty-four.

The strong observations I had before made upon this deeply interesting subject, and published in the *Dublin Journal of Medical Science* for March, 1837, and some of the succeeding numbers, to which I would specially

refer, were made, as you are well aware, to counteract the *hasty*, and if generally acted upon, *mischevious*, *measures*, urged at that time by the late Professor Hamilton, for the *artificial dilatation* of the mouth of the womb within twelve or fourteen hours, and the *actual delivery* of the patient within twenty-four hours from the commencement of labour.

I now apprehend, if possible, greater danger, should your theoretical proposal be acted upon, and as it holds out the very strong inducement, of at once relieving the practitioner from the fatigue of a protracted and anxious attendance, the thoughtless or careless might possibly be unable to resist this great temptation, if not *forewarned* of the fatal consequences to both mother and child.

Of the fifteen cases of protracted labour we have recorded, which proved fatal, *fourteen* were delivered of *first* children, all *males*, which clearly points out the greater size of the *male*, and greater ossification of its head, as one of the chief difficulties to be encountered. How can any practitioner pretend to know, in the *early* stage of a *first* labour, (except where the diminution is extreme, which is rarely to be met with,) whether the pelvis be of such a size as to permit the head to pass, or whether the ossification of the head be such as to yield to the force of uterine action?

We totally disbelieve in the *accuracy* of the minute measurements given by some writers, of the brim and outlet of the pelvis in the living subject; and even were we certain of its capacity, a child of 7lbs. or 8lbs. weight would pass with *facility*, where one of 10lbs., 12lbs., or 13lbs., could, by *no possibility*, be delivered without diminution.

To turn a child in the *early* stage of a *first* labour, where we can have no knowledge as to the practicability or impracticability of the natural effort to accomplish the delivery, is in my opinion wholly unjustifiable. Our registry *proves* that the mortality is merely confined to *first* pregnancies, where there has been no previous knowledge of the capabilities of the pelvis, and where, under ordinary circumstances, the rigidity of the soft parts, renders turning hazardous to both mother and child; but where deformity of the pelvis exists, or where the child is extremely large, as is invariably the case in very protracted labours, the results must be disastrous. I venture to prognosticate, that out of 79 such *trying* cases as we have reported, the mortality, instead of 15, would be much nearer to one-half of the total number of mothers; and a living child would be a rare event. Over and above the sad evils resulting from its adoption in *really laborious labours*, we shall have innumerable bad consequences from the turning of the child, in order to *expedite* the labour, *where no deformity or disproportion whatever exists*. In truth I see no limit to such mischievous proceedings, where chloroform is used, and the attendant is not conscious of the real dangers of turning the child.

Perhaps you are not aware of the *fact*, that in hospital, when puerperal fever prevails, the introduction of the hand into the uterus for *any* purpose, is usually followed by the most fatal results,—so much so that few escape. This should be carefully recollected, and when a tendency to puerperal peritonitis exists out of hospital, the risk is very great.

I shall now notice your statement that "the infantile mortality attendant upon parturition increases in a ratio progressive with the increased duration of the labour."

In reply to this theory, I shall only state the simple truth which you have *omitted*, that of 1045 cases of still-born children accurately noted; *eight hundred* and *forty-four* were delivered within *twelve hours*, and *nine hundred* and *thirty-two* within *twenty-four* hours; and I have added, that the death of the child *subsequent* to birth, except in *very few* instances comparatively speaking, was not a consequence of injury arising from *protracted* labour; for of the 284, which was the *total* number of deaths, previous to the mother leaving the hospital, the labour in 246 did not exceed *twelve hours*. These unquestionable facts extinguish all speculative theories. I have also stated, when we consider the class of patients admitted into the Institution, where *extreme* poverty is the only passport demanded,—and the *very great number* admitted after having been *one*, *two*, *three*, or *more* days in labour, most of whom are grossly mismanaged,—besides the numerous cases sent in actually *almost dead*, as the reported cases witness, the success of the treatment pursued will be still *more* apparent.

That your opinions should totally disagree with mine, on the advantages to be derived from the use of the stethoscope, as a means of ascertaining the life or death of the child, in *trying cases of protracted labour*, is what I had no doubt of; and when you state the mighty boon which auscultation offers us in such cases to be, the delivery of the infant with the *long forceps* so as to *preserve* its life, few will wonder at our disagreement! Had I not made a better use of this invaluable assistant in the 79 cases we met with, the mortality would not have stopped at fifteen, nor twice that number.

I could not picture to my mind a greater outrage in practice, than the attempt to drag a child through a deformed pelvis, or an extraordinary large child through an ordinary pelvis, with the long forceps, *more* especially as I have proved that the most trying cases are met with in *first* labours, where no relaxation of the soft parts can take place so long as the head remains at the brim of the pelvis; also, that in most laborious labours the pelvis measures little more than *three* inches from the pubes to sacrum; in others less than this; and that when we consider the blades of the smallest sized long forceps used in Britain, even when *completely closed*, measure from $3\frac{5}{8}$ inches to $3\frac{1}{2}$, it is clear that were the bones of the pelvis denuded of their *soft parts*, there would not be space to admit of their application. Your observations upon my recommendation of the use of the forceps in prolapsus of the umbilical cord, when *the child is so situated as the head can be reached with safety*, are strongly misapplied, as in the one case there is ample space to use the instrument without injury to either mother or child, whereas in the other I have already shown this to be impracticable, without exposing the patient to unjustifiable danger. It is to be supposed, if you had not some experience of the mischievous effects of the long forceps under such circumstances, you would not now be so anxious to abolish the use of them; but as we say in Ireland, you have leaped "out of the frying pan into the fire."

As you so fairly state that I am the only writer who furnished the profession with data showing the duration of labour, either in natural or operative cases, and that my "Practical Treatise on Midwifery" is a work, the great value and candour of the facts contained in which it would be difficult to overpraise, I would solicit from you, in return for the information which cost me so much labour to supply to my professional brethren, that henceforth, and upon all occasions, either in your lectures as a University Professor, or in your writings,

you would plainly state the *total* number of cases under each head you refer to, and at the same time give the *No. of the case* which is *affixed* to each, in order to enable the profession to judge for themselves of the correctness of reference.

I would also *claim* from you, as a reward for my industry, that when you refer to the mortality of the patients under my care, and recommend a *different* mode of treatment, you would honourably state, that Dr. Collins' practice, which you propose to improve, is much the most successful on record, as you know of no report of 10,785 cases, with a mortality nearly so small as *one* in *one hundred and eighty-six*. This is only an act of *simple justice*, and I should not object to your *then* adding, if Dr. Collins had adopted *my* treatment, *none* of the patients would have died.

I feel called upon to seek the declaration of this *important truth* from you *in future*, as in your essay lately published on "The Use and Effects of Chloroform in Obstetric Practice," you set forth, in the most feeling manner, the "*sufferings*" of the patients, and the number that "*perished*" from prolonged labour under my care; whereas, if you had fairly stated the facts I had so clearly adduced, your theoretical calculations must have proved visionary. I would not now allude to this essay had its circulation been confined to our professional brethren, (to which I have no doubt *all* medical men agree with me in thinking it should have been strictly limited,) but finding it has been introduced into the domestic circles, where I cannot consent to correct the statements it contains, I am induced to request you to blend with your popular writings a more equitable portion of merit to me, as I believe you would not intentionally "pluck the laurel off my brow," or withhold what I hope you will agree with me in thinking I may from you legitimately claim.

I am, dear Sir,
Very faithfully yours,
ROBERT COLLINS.

Merrion Square, Dublin,
Oct. 6th, 1848.

P.S. Since the above letter was forwarded for publication, Professor Simpson has been so good as to send me a Report on "Anæsthetic Midwifery," which he has just published in the *Edinburgh Monthly Journal of Medical Science*, detailing the results of cases that occurred in his private practice, and also under his care in the Edinburgh Lying-in Hospital, from January, 1847, to October, 1848, being a period of one year and nine months. From this Report it appears that in Dr. Simpson's private practice about 150 patients were delivered in a state of anæsthesia, and that there were 20 or 30 other cases of labour in which anæsthesia was not employed. The total number of those cases we may calculate as 170, four of which died, or in the large proportion of 1 in 41. In reference to this result, I can aver that we know of no such mortality in Ireland. I have been more than a quarter of a century engaged in the profession, with a reasonable share of practice in the highest ranks of society, and during the whole of that time I have not met with a greater number of deaths in my midwifery practice, than Dr. Simpson has reported in the twenty-one months; and I have now nearly ready for publication, the entire results of the late Doctor Joseph Clarke's private practice in this metropolis, extending over a period of nearly fifty years, and exhibiting an accurate and unprecedented record of three thousand eight hundred and forty-seven cases, which fully corroborates my statement. The information I have to publish will, I entertain no doubt, prove of extreme interest to the profession, as hitherto we have been left in total ignorance of the accurate results of extensive private practice in the higher ranks of society.

The following account of the results of anæsthesia in the practice of the Edinburgh Lying-in Hospital, has been furnished to Dr. Simpson, by his resident assistants, Dr. Duncan and Mr. Norris:—

The use of anæsthesia in labour became general in the hospital shortly after the discovery of chloroform, since which, 95 women in all have been delivered in the house under its influence; among these, 63 were natural, and seven were morbid labours. Of the 95 cases, three mothers died, or in the frightful proportion of one in 31; of these three cases, one died of convulsions, one from sloughing of the maternal passages, subsequent to the long forceps, and one from rupture of the uterus, where the child had been turned. Fifty cases were delivered in the hospital without chloroform, but as the result to the mother and child is not given, they are not to be included. When we compare the above mortality with what I have reported of the Dublin Lying-in Hospital, under similar circumstances,—namely, one death in 186 cases, I am satisfied my professional brethren will admit the justice of the acknowledgment I have demanded from Dr. Simpson, on all future occasions, when he thinks fit to criticise my practice, and, on points of such vital importance, to introduce my work as his authority.

The fatal results in the Edinburgh Lying-in Hospital, as now furnished by Dr. Simpson, closely approach the unprecedented mortality of the same Institution in 1821 and 1822, of one in 21,* which unfortunately is the only record in existence of the mortality in this public charity.

Had the deaths been one in 31 during my Mastership of the Dublin Lying-in Hospital, I should have had the melancholy duty of reporting the appaling number of 529 deaths instead of 164.

* *Dublin Medical Journal*, 1837 and 1838.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF PROFESSOR SANDS COX, F.R.S., SENIOR SURGEON TO THE HOSPITAL.

Reported by PETER HINCKES BIRD, Resident Medical Officer.

CASE IX.

DISLOCATION OF THE WRIST.

Elizabeth Smith, aged 13, admitted as out-patient on the 23rd of December, 1846, under the care of Professor Cox. It is stated that she had just slipped down while crossing a slide; she fell on the palm of the left hand, the fingers being extended.

On admission there was found a considerable swelling, produced by the radius and ulna, on the fore-part of the wrist, and a similar projection on the back part of the wrist, with a hollow above it; the hand was bent back,

and the motion of the wrist impaired; the styloid process of the radius had not its proper relation with the trapezium, but was thrown on the scaphoid and trapezium. A careful examination was made, but no fracture could be detected.

Reduction was easily effected by extension, a bandage was afterwards lightly applied round the wrist, and the fore-arm supported by two pasteboard splints before and behind, extending as far as the extremities of the metacarpal bones. Ordered to keep the wrist damp with Lotio Plumbi.

24th. Doing well; there is some slight pain on motion, and swelling of the joint; there is no deformity.

27th. Discharged.

It was the opinion of Dupuytren, "that there was not a single unequivocal instance on record of a dislocation of the *radio-carpal* articulation; and that he invariably found these pretended accidents always turned out to be fractures of the radius, near the articulation." He quotes the following lines from a memoir "On Fractures of the Fore-arm," by Ponteau:—"Ces fractures sont le plus souvent prises pour des entorses, pour des luxations incomplètes, on pour un écartement ou du cubitus, ou du radius à leur jonction vers le poignet." Desault also, in noticing fractures of the lower end of the radius, adverts to their having been sometimes mistaken for dislocations. "At the present time," says Dupuytren, "there can be no doubt about the frequency of fractures of the lower end of the radius, and about the impossibility, or at all events, the extreme rarity of dislocations."*

In this case there was not the slightest evidence of a fracture, for the patient, within a few days after the accident, could perform all the motions of the joint, and make use of her arm, which would not have been the case had fracture been present.

Swelling of the flexor tendons opposite the wrist-joint, from sprain, assumes the appearance of dislocation, but they may be easily distinguished; in the former the swelling comes on gradually, whereas in the latter, it is seen immediately after the accident. Besides, in dislocation, the relative situations of the styloid processes of the radius and ulna with the carpal bones is altered, but not in sprain.

Fractures near the wrist-joint may, as above stated, be confounded with luxation, but they may be distinguished by simply moving the hand; if there be dislocation without fracture, the styloid processes of the radius and ulna will not change their situation by its motion. In fracture the processes will follow each movement of the hand.

Case X.

Fracture of the lower end of the radius.

Elizabeth Sewell, aged 61, housewife, admitted as out-patient, on the 4th of May, 1847, under the care of Professor Cox. She states that a few minutes ago she fell down, and putting out her hand to save herself, she felt something give way at her wrist, and immediately lost the use of her arm.

When admitted there was considerable distortion of the fore-arm; the movements of pronation and supination were lost. On taking hold of the patient's hand, and rotating the radius, a distinct crepitus was felt, about one inch and a half above the wrist; there was also considerable pain on supinating and pronating the hand, the upper fragment of bone remaining motionless; there was no fracture of the ulna; there was a slight wound on the outer side, at the lower third of the arm, but it did not communicate with the broken bone.

A long splint, well padded with cotton-wool, was placed on the outer side of the fore-arm, reaching from the elbow to the ends of the fingers; and another splint, also well padded, from the bend of the elbow to below the wrist; and the arm was placed midway between pronation and supination, the hand being allowed to drop. The wound was dressed with simple dressing.

7th. The wound is nearly healed; the arm is in good position; and she complains of pain.

10th. Wound quite healed; is free from pain.

20th. Doing well; the bone is in good position; there is no deformity.

June 1st. Splints removed, and a starch bandage applied.

12th. Discharged cured.

Fractures of the radius are perhaps of more frequent occurrence than those of any other bone in the body, except the clavicle; this is accounted for by its articulation with the carpus, thus receiving all the force communicated to the hand in falling. It generally gives way in the middle-third, but sometimes near the wrist. A fracture of the upper end of the radius rarely, if ever, happens in this manner, but when occurring, is produced by direct violence. In a paper on "Fracture of the Lower Extremity of the Radius," by Professor Ferger, of Copenhagen, is given a tabular view of 149 cases of fracture, which came under his notice, of which number it appears that thirty-one were fractures of the radius alone, and only one of the ulna alone; and from this table he infers that the radius is more frequently fractured than any other bone, and more than twice as often as the fibula. It appears that the accident is rather more frequent in men than in women; and age predisposes to this lesion. In treating of the symptoms of fracture of the radius low down, the author associates great importance with the deformity, as a diagnostic sign by which the injury may be distinguished from sprain. The straight line extending along the radius and metacarpal bone of the fore-finger, appears to be broken in two places,—1st, closely over the styloid process of the radius; 2nd, between the carpus and metacarpus. This line is hereby divided into three parts, of which the superior and inferior portions are parallel, and the centre and shortest one forms an angle with the other two, like the letter Z. Of these two angles, the upper one is always present in this fracture, and remains unchanged by any position of the arm.

Fracture of the lower extremity of the ulna, extravasation into the articulation, and luxation of the radius from the ulna, constitute some of the complications of fracture of the radius low down. The fracture is generally oblique, beginning on the palmar side of the lower end of the radius, a little above the articulation, and proceeding upwards towards its dorsal aspect, where it terminates from an inch to an inch and a half above the joint.

* Clin. Chir., tom iv.

Professor Ferger describes the plan of treatment he has found most successful. He states, that as the deviation occurs in a curve, with its centre upon the fracture, it is desirable to counteract the deformity by extension, acting in a direction according to the tangent of that curve. This end he thinks is best attained by acting through the medium of the hand and capsular ligament, which is attached to the lower end of the radius. The hand is first to be brought into a state of strong flexion, and the fore-arm is then placed on an oblique plane, with the carpus highest, the hand being permitted to hang freely down the perpendicular end of the plane; the tendons of the extensor muscles are thus brought into a position which enables them to assist in keeping the reduced fragments of the bone in proper relation. In the treatment of these fractures, it is also a grand point to preserve the interosseous space perfect; for if this indication is neglected, the radius and ulna may grow together, and the motions of supination and pronation be for ever lost. In the above case this was prevented by placing a pad of lint over the interosseous space.

In 1842 there were treated, at the London Hospital, 840 fractures, of which 153 were of the fore-arm; in 1843, there were 899 fractures, and 156 of the fore-arm; in 1845, 952 fractures, 200 of which were of the fore-arm; and in 1846, 954 fractures, with 176 of the fore-arm.

The frequency of this fracture must be acknowledged, and also the repeated failures attending its treatment, (it is said that Velpeau cures but thirty cases out of fifty,) thus causing a partial, if not a total, loss of the use of the hand and fingers to a great number of our fellow-creatures.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, OCTOBER 18, 1848.

We have received from the Central Board of Health the official document which has been recently issued by the Board on the subject of Cholera. It is not our intention to offer any extended criticism upon this document, but we cannot but express the conviction, founded partly on personal experience of the epidemic of 1831-2, and partly on a careful consideration of the facts then and since recorded with regard to the progress of the present and former visitations, that the opinions therein expressed on the subject of contagion are somewhat hastily put forth. In the very doubtful state in which this question at present rests, the safe error would have been on the side of precautionary measures, while the recommendation to receive cholera patients indiscriminately into general hospitals, appears to us most injudicious. The following directions form the most important part of the document and should not be lost sight of:—

"*Nature of the Attack.*—It seems to be a well established fact, and one that cannot be too strongly impressed upon the minds of the people generally, as upon this fact depends the best hope of successfully contending with the disease, that in nearly all cases of Cholera, there are two stages of the disease, the *first* being merely Diarrhœa, or simple looseness of the bowels; the *second* being the stage of Collapse, or Blue Cholera, marked by cramps, failure of the circulation, lividity of the skin, cold, clammy perspiration, and all the other well-known symptoms of the disease. In the first stage of the disease medical treatment is frequently successful, in the second stage too often of no avail.

"The first stage, *Diarrhœa, or mere looseness of the bowels,* may be of only a few hours' duration, or may continue from one to several days. It is most important to bear in mind that this Diarrhœa *may be entirely without pain;* indeed, it most frequently is without pain, or merely accompanied with trifling griping or uneasiness. This absence of pain, or the little accompanying uneasiness, has too often thrown the patient off his guard, who has thus neglected the warning of his danger, and has allowed the time for cure to pass by.

"It may be safely asserted that, during the prevalence of an epidemic of Cholera, Diarrhœa, or looseness of bowels, which is free from pain, is more dangerous, more likely to be the first stage of the disease, than Diarrhœa accompanied with griping or pain. Let it then be clearly understood, that *when the epidemic is prevalent, mere looseness of the bowels, with or without pain, may be the commencement or first stage of Cholera—that the disease is generally curable in this stage, and that not a moment should be lost in applying for relief.*

"To afford this immediate relief, the Commissioners of Health recommend that every existing Medical Institution, whether Hospital or Dispensary, should be open, day and night, during the prevalence of Cholera, to all applicants, without distinction, where all who apply should obtain, without *a moment's delay*, advice and medicine; and from which all the poor, who may be unable to leave their dwellings, may be visited with promptitude, and supplied with medicine at home, or transferred, if requisite, to Hospital."

It is further recommended by the Board, that "the visiting physician, instead of writing a prescription at the residence of the patient, should be provided with a small portable pocket-medicine-box, containing the medicines most generally required, made up in such a form as to render their administration as speedy and as simple as possible. Such portable medicine-boxes

can be procured at a very small cost, or may be made up on an emergency, of pasteboard, or thin board, or tin, in the form of a book about 7 inches long, 4 inches broad, and 1 inch deep, with one of the sides to fold back, or open on hinges."

The following list is given as an example of what should be provided in the pocket-medicine-boxes:—

Carbonate of Ammonia, in waxed papers, each paper containing 40 grains, with the following printed directions on the outside:—"Dissolve this Powder in half a pint of water, give two table-spoonfuls every hour."

Compound Powder of Chalk with Opium, in packets each containing 6 papers, each paper containing 10 grains of the Powder, with printed directions:—"One Powder every half-hour, until the looseness ceases."

Pills of Powdered Opium, each containing one quarter of a grain of Opium, and two grains of Powdered Ginger, made up with Oil of Peppermint. The Pills to be in boxes, each box containing 6 Pills, with a printed label:—"Opium Pills, one every half-hour, until the looseness ceases."

Pills of Mercury and Opium, each containing one quarter of a grain of Calomel, two grains of Hydrargyrum cum Creta, and a quarter of a grain of Opium, made up with *Oil of Caraway*, in Boxes, each containing 6 Pills, with a printed label:—"Mercury and Opium Pills, one every half-hour."

Some one or two ounce phials, with *cork* stoppers,—containing—1. Tincture of Opium (Laudanum); 2. Hoffman's Liquor; 3. Tincture of Rhatany; 4. Creasote. Along with the box should be carried a small jar of strong brown mustard.

Proceedings of Societies.

NORWICH PATHOLOGICAL SOCIETY.

August 17th, 1848.

President—Mr. Crowfoot, of Beccles.

ENLARGED PROSTATE, WITH DISEASED BLADDER AND KIDNEYS.

Mr. J. G. Johnson related the history of this case, which had been under his notice for many years, during which period he had, at one time or another, extracted upwards of eighty prostactic calculi. At this time the bladder was not affected, but the prostate gland was much enlarged. The patient had also an hydrocele on one side, and a large hernia on the other. The bladder subsequently became affected, and he eventually died comatose. On examination no calculi were found in the bladder; ureters enlarged; right kidney full of calculous matter, whilst the left kidney was contracted, its parenchymatous structure quite deficient, and the ureter impervious; bladder contracted and small; prostate gland very much enlarged, (almost as big as the fist.)

RUPTURE OF THE BRONCHUS.

Mr. A. Dalrymple stated, that the subject from whom this specimen had been taken, was a man upwards of 70 years of age, who had been thrown out of a cart, and admitted into the Norwich hospital with compound fractures of both femurs, extending into the knee-joint, as well as other severe injuries, from which he soon died; upon a *post-mortem* examination, the liver was found occupying two-thirds of the cavity of the right pleura, in consequence of the lung having collapsed, owing to a rupture of the right bronchus.

A discussion arose as to whether this rupture was the result of the man's having fallen backwards from the cart, or was caused by the ends of the broken ribs. There was, however, no emphysema, and no wound in the pleura, to be detected.

ANEURISM OF THE CAROTID ARTERY.

The Secretary read a communication, received from Mr. Hunter, of Lynn Regis, together with the specimen referring to the case, which was as follows:—

A person, aged 60, of spare habit of body and nervous temperament, complained on the 21st of January, 1843, of suffering from what was then thought to be inflammatory sore-throat, and was considered convalescent on the 3rd of February following. At that period there was great debility of the system, which she attributed to past mercurial treatment. She returned in May, 1843, complaining of soreness of the throat, and difficult deglutition. On examination, the site of the tonsil appeared occupied by general intumescence, which extended to the arch of the soft palate, was of a livid colour, and covered with aphthous specks. The tonsil itself appeared lost in the general swelling, and communicated a decided pulsation to the fingers on compression. The patient had consulted another medical man, who ordered her a gargle, and recommended her having the part lanced. Having carefully examined, and being satisfied as to its aneurismal character, an operation was advised, to which the patient agreed to submit. The common carotid was accordingly secured in the usual place, just above the omo-hyoid muscle, on the 3rd of August. She did not lose more than a teaspoonful of blood. Some little difficulty was experienced in passing the aneurism-needle, from thickening of the connecting membrane. She bore the operation remarkably well, but required a small quantity of brandy before being removed to her bed. The integument was then brought together by suture, and the wound coated with a solution of fine glue, or oiled silk, over which a small compress of lint was placed, so as to keep up a moderate pressure, and strips of adhesive plaster, completed the dressing. At nine, p.m., she was tranquil, the sight not more than usually clouded; pulse 78; in all respects going on favourably.

August 4th, nine, a.m. Has passed a good night, with several hours sleep; pulse soft and full, under 80.

Seven and a half, p.m. Complains somewhat of dorsal pain, extending across the body; some uneasiness

of the throat; pulse under 80; general surface comfortably warm; tongue moist, whitish, and chalky. R. Magn. Pil. Hydrarg., gr. v., hora somni sumenda. Mist. Magn. Sulph. cum Ol. Menthæ, ad alvum solvendum.

Matters appeared to progress favourably till the afternoon of the 7th, when, desirous of re-adjusting her body-linen, she was unadvisedly allowed for some minutes to sit on the side of the bed. She was said to have fainted. I was called to her immediately, being at the time in an adjoining apartment. I found her with dilated pupils, a pulseless wrist, and life extinct. This occurred about half-past four, p.m., Monday, August 7th, four full days subsequent to the operation.

Some doubts after her death having been expressed as to the case being one of aneurism, permission was obtained to examine the parts connected with the operation.

On Tuesday, August 8th, a *post-mortem* was made, and it was ascertained that the parts connected with the operation held out every prospect of a successful issue, and placed beyond a doubt the correctness of the diagnosis. The incision in the sterno-mastoid measured about two inches and three quarters; but slight adhesions were noticed connecting the lips of the outward wound. When detached, the aneurismal tumour was about the size of a pigeon's egg, the walls were lined with concentric laminæ of fibrin, and the centre filled with coagulum; the ligature had been justly and duly applied; the artery was everywhere adherent to its sheaths, laterally and posteriorly by its natural tissue, and anteriorly, where it had been exposed for passing the aneurismal needle, by recent adhesions. On opening the vessel above and below the ligature, a conoid plug of coagulated blood, apparently coated with lymph, filled the arterial calibre. The internal and middle tunics had been clearly divided by the ligature, and the freed circular edges were found puckered and retracted. The pneumo-gastric nerve, and the interal jugular vein, in connection with the carotid, were undisturbed, and free of morbid appearance; indeed, from the state of the parts themselves, there was good reason to have hoped for her recovery. As the head, thorax, and abdomen, were not examined, the absolute cause of death can only be conjectured; the greater probabilities are, that it was occasioned by a rupture of a diseased vessel in one of the larger cavities, or in the head, or it may have been induced by the semi-erect position too long maintained before the brain had accustomed itself to the altered circulation.

It has been remarked, that many of the subjects of aneurism have at some former period of life undergone mercurial treatment for some form or other of venereal disease, but whether this be merely an accidental coincidence, or the sequence of venereal action, mercurially treated, has not, I believe, as yet, been satisfactorily determined. The pneumo-gastric nerve, and the glosso-pharyngeal, had apparently suffered from compression, when passing the aneurismal sac, which possibly was one cause of the dysphagia and sense of impending suffocation at times experienced.

Mr. Hunter also sent another specimen of aneurism of the aorta. The subject of this case had also been previously mercurialized for some venereal disorder.

ATRESIA ANI.

Mr. T. W. Crosse exhibited a specimen taken from an infant, who was born with an imperfect anus. An opening was made into the rectum, and the meconium allowed to escape. The child lived for six weeks, the motions passing partly by the urethra, and upon a *post-mortem* examination, the rectum was found to terminate in the urethra by an opening just below the uvula vesicæ.

Mr. Thurgur produced a specimen of enlarged thyroid gland, which had caused death by compression of the trachea.

Mr. C. Broughton exhibited a specimen of diseased lung, taken from a patient who died at the Norfolk Lunatic Asylum. During life she had suffered from the symptoms of chronic bronchitis; but after death a large deposition of tubercular matter was discovered at the base of the right lung. A question arose as to whether this deposit was simply tuberculous matter, or tuberculous matter surrounded by hepatized lung.

A specimen of foul ulcer of the back of the hand, supposed by Mr. Currie, of Bungay, to be of a malignant character, was exhibited, and in consequence of his having thought that he detected an enlarged gland on the inner side of the upper arm, just above the elbow, he had amputated above that joint, a proceeding which was not thought to have been necessary by many of the members present.

Foreign Department.

CLINICAL SURGERY.—THE WOUNDS OF JUNE, 1848.*

(Translated from the *Annales de Thérapeutique*, by T. W. Crosse, Esq.)

At the Hôpital St. Louis, under M. Jobert.

The number of wounded is considerable. The number admitted on the 1st of July is about 400. More than one hundered others who were admitted at the same time sank almost immediately from the seriousness of their wounds.

We are struck on entering this hospital, with the absence of all military appearance; there is no sentinel either in the court, the hall, or before the gates. The wounded insurgents lie indiscriminately by the side of the soldiers of the National Guard, and apparently, no measure has been taken, as at La Charité, to prevent their escape. They are all treated alike, with the same care and kindness. Those wounded with muskets, of which there are a great number, are only met with among the combatants on the side of the insurgents. Among these same wounds, one only was very serious; it had produced an enormous mutilation of the lower jaw, the reaction of which proceeding towards the larynx caused death. The others are principally

* Continued from page 553.

situated on the extremities and accompanied with much injury to the soft parts; upon the whole they are simple and in a fair way towards recovery. Many wounded women also have been received into the hospital. Those who were wounded in the chest or belly have died, but there are eight remaining in the wards. One has had her leg amputated. Among these female insurgents there is one whom we must specially mention. She is a young woman whose whole body is horribly mutilated by the explosion of a large quantity of powder. This unhappy person was devoted to the manufacture of this material, and it was while drying it rapidly in a pan too highly heated, that the accident occurred. They covered her body with cerated linen and bladders half full of ice. Many operations have been performed. One patient, whose thigh was amputated by M. Jobert, is since dead; and so are some four or five others, who had either their thighs or legs amputated by M. Gosselin. All these amputations were high up, and it was found after death in many, that the bone of the stump was vertically split to a great extent and the marrow itself affected. Of two amputations at the shoulder joint one has died. There are a great many who were wounded, by volleys of fire, in the thigh and leg, attended with extensive fractures of the bone, and which, not having been amputated at once are now in a somewhat perilous condition. There are two cases in whom the arm has been amputated, and they are doing well, but the difference is great between the danger of amputating the lower and upper extremity. Lastly, there are a great number of patients who have been wounded by spent balls." These make little round openings, very superficial and small, as if they had been formed by the rapid passage of a pencil dipped in some strong acid They are not very severe.

In detailing particular cases, we have but little to remark; the wounds resemble more or less those already described. The following, however, are of especial interest:—We meet with no wound about the cranium, for all injuries of this description generally prove fatal on the field of battle, or very soon after their admission. On the face we find two cases which call for our attention. The first refers to a young officer, who was struck by a ball in the external angle of the right orbit, and the missile passing from without inwards struck the eye, and consequently deprived him of this organ. This mutilation did not retard the brave officer in his course, and it is probable that he will be able to wear an artificial eye. The second case is that of a young insurgent, who was wounded in the left cheek, and the superior maxillary bone fractured. The wound opens into the mouth so as to admit the introduction of five fingers in the form of a cone. The edges of this great wound are gangrenous and swollen, and the recovery will doubtless be protracted and attended with much deformity. It is probable that some Taliacotian operation will be necessary to fill up the large chasm which exists.

There is no case of injury to the vertebral column, for the same reason as that referred to when speaking of injuries to the cranium; nor any of injury to the neck. There are a great number of cases, more or less severe, of penetrating wounds of the chest. In one, the ball passed quite through the upper lobe of the lung; in others, there was only one opening, and the ball is concealed. All these patients have been bled at various times, and kept on strict diet; they are going on very well, and we may count on the recovery of a greater part of them. Without doubt this result may be attributed to the frequent venesections; but we would ask, whether the situation of the injury at the apex of the lung, is not more favourable to recovery than one at the base would be. Modern writers on medicine state pneumonia at the apex of the lung to be the more severe, but their arguments are not exactly applicable to wounds from fire-arms.

There is only one case of injury to the abdomen worthy of remark. A young man received a ball in the right iliac fossa, at a little distance from the inner side of the crest, which passed out at the buttock, through the bone on the opposite side. The cæcum, if not the peritoneum, was wounded; there has not, however, been at present any escape of fæces or peritonitis.

There has been a great variety of wounds in the upper extremities, but nothing remarkable. In the lower extremity the number of lesions are very numerous and various. We would speak, first, of penetrating wounds of the knee-joint, with, or without, the passing out of the ball, and either with, or without, comminuted fracture of the condyles of the femur or of the head of the tibia. M. Jobert treats all these cases as simple wounds, without seeking to extract the splinters, or submitting the limb to cold fomentations. It i difficult to say at this moment what will be the result of these wounds; it is probable that many will require amputation, unless their condition becomes so complicated as to deprive them of the benefit of an operation. We would mention, next, a case where the bullet is buried in the front of the tibia: it occurred to a young man who had previously had necrosis of the same limb; the ball is "nested," penetrating very deep, and rests as in a cyst. Larrey has mentioned an analogous case, where the ball was encased in a bony cyst, formed in the medullary canal of the tibia, the ball shaking about in the cyst like a little bell.

Treatment.—We would say a few words on the treatment of the wounded, adopted by M. Jobert. In all cases where there is manifest aponeurotic tension, he makes deep lateral incisions, parallel with one another, on each side of the wound. These cuts, already commended by Larrey, are about four or five centimetres in length, and penetrate to the first aponeurosis. M. Jobert thinks this treatment prevents or dissipates the strangulation of the limb. This practice not being generally adopted, it may be asked whether it answers the ends he attributes to it, for what is the cause of the tension and strangulation? It is, without doubt, inflammatory congestion. Now, as M. Jobert prescribes for these patients abundant bloodletting, and the application of numerous leeches, we might attribute to these means the same end that he gives to the incision. Dupuytren has, it is true, adopted this treatment in

cases of whitlow, but it is not followed at this time Local and general abstraction of blood is adopted much by M. Jobert. In wounds of the chest, frequent venesection is practised; one patient was bled seven times in a few days; and the best results may be attributed to this treatment. Local bleedings are effected by the application of about forty or fifty leeches at a time around the wounds of the limb. We may remark here, that in military hospitals, on account of its cheapness, they use the cupping glass instead of leeches.)

With respect to the dressing of the wounds, M. Jobert uses cold emollient poultices, moistened with the water of the marsh mallow. This practice is excellent, for it softens the wounds, and hastens the separation of the sloughs. Some surgeons prefer the incessant fomentations of fresh water, or of abundant irrigations. Of internal remedies, M. Jobert employs only one, and that is opium, which he gives in the form of a pill, with the view of soothing pain, and procuring sleep. This theory, however, is contradicted by experience; opium, like brandy, is an excitant, and does not sooth the pains of inflammation; and it is a delusion on the part of M. Velpeau himself, who applies it locally to wounds, with the intention of lessening the suffering. Believing in this false idea regarding opium, we fail to assure ourselves of the real virtues of other medicines.

At the Hotel Dieu, under M. Blandin.

About 120 wounded have been admitted into his wards. In inspecting them we are struck with the great severity of the wounds. Lesions of the trunk are frequently met with, owing no doubt to the great fury with which the combat was carried on. Many of the wounded died soon after their admission, and many more in all probability will die. Another point we would wish to notice is the great success of the amputations. M. Blandin has operated ten times. These operations are,—one of the thigh; two at the knee-joint, one of whom is dead, and the other will die; four of the arm, one of whom is dead; and three of the leg. So that out of ten amputations there have been only three deaths. Up to the present time the mortality averages about one in three. In all the hospitals the ravages of death among those who have submitted to amputation are frightful, owing in part to the severity of the injuries, and the time which elapse before they came under treatment.

Of the *head*, there have been many severe wounds, but they all died very soon. Of the *face*, we shall mention only one, and that is of an individual who was struck by a ball in the right eye without wounding the eyelids; the eye is destroyed and reduced to a moveable stump. The ball has not been found. M. Blandin supposes that it has escaped with the contents of the eye without the patient's perceiving it. There are, however, cases on record, of balls buried in the depths of the orbit behind the globe, where they have remained undiscovered for years.

There is one case where a ball had traversed the soft parts of the *neck*, from the sterno-mastoid muscle to the level of the larynx, passing out behind near the vertebræ without wounding any vessels or nerves. All the tissues passed over are much swollen, but upon the whole it is likely that the patient will quite recover.

In the *chest*, there are many cases of perforation quite through, at different heights. Some present only one opening, the ball being lost in the thorax. One received a ball from above downwards, which fractured the left clavicle and entered the thorax, where it remains. In another the ball perforated the anterior mediastinum, and is likewise lost. There are some who have been wounded from behind at the base of the lung on one side, and the bullets passing out at the apex of the opposite lung, so that the two lungs have been traversed diagonally. Others have received the same sort of diagonal wound, only in the opposite direction. There is one thing that has struck us among so many perforating wounds of the chest, and that is the absence of pulmonary hernia, and of general emphysema. There are many cases of penetrating wounds of the abdomen, in some of which the ball has not been found.

Of injury to the limbs we shall only mention one case, and it is one where the crural artery was wounded near its upper part by a ball. It has caused an aneurism of large size, extending downwards to the middle of the thigh, and upwards to the iliac fossa, the principal development being upon the internal and anterior aspect of the thigh. The aneurismal bruit can be heard; the wound is almost cicatrized; and there is no external hæmorrhage. Ice has been applied, and it is probable that the external iliac artery will have to be tied.

Treatment.—Simple dressings, (like those used by M. Velpeau.) No poultices nor irrigations. Blood-lettings; dieting and purgatives constitute the principal remedies adopted by M. Blandin.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS.

DEATHS FROM CHLOROFORM.

After a brief discussion on the *questio vexata* of the connection between the spleen and intermittent fever, the subject of chloroform was again brought forward, but under less favourable auspices than heretofore. Two instances of death from this agent were recorded, one which occurred at Boulogne, the other in Paris. The former case was that of a young female, who required the simple operation of opening a sinus. Twenty drops only of chloroform were used, and the handkerchief was held to the mouth for a few inspirations only, when the patient cried out that she was stifled; her lips became blanched, and death occurred in spite of every attempt to prevent the catastrophe. After death the heart was found empty, the veins of the cerebrum and base containing bubbles of air, as was also the case with the internal saphena and crural veins, the vena cava and pulmonary veins. The lungs were partially engorged.

The second case was that of a man, in whom amputation at the hip-joint was attempted, for comminuted fracture from a gun-shot wound. During the

operation sudden pallor, with stertor, ensued, and the man sank apparently from syncope.

The first of these cases gave rise to a brief discussion. The narrator, M. Gorré, attributed death—1, to the deleterious action of chloroform on the brain; 2, to the spontaneous generation of air in the blood, which was probably the result of some unknown action of the chloroform upon that fluid. During the discussion many diverse opinions were elicited. M. Velpeau regarded the case as one of those unfortunate accidents which occasionally occur during operations, and one quite independent of the anæsthetic agents; and the same opinion was held by M. Baillarger. MM. Gibert and Piorry considered the fatal event to have been due to introduction of air into the blood by rupture of the pulmonary tissue.

M. Mialhe produced a memoir entitled, "New Researches on the Pathology of Diabetes," the principal feature of which consisted in the narration of a case cured by the alkaline treatment. The patient took five drachms of bicarbonate of soda, one drachm of calcined magnesia, and two bottles of Vichy water, during the day.

NOTES FROM A PRACTITIONER'S DAY BOOK.*

PAINS IN BONE.

Under ordinary circumstances, bone appears to have very little feeling: it may be sawn, broken, or struck, without these injuries exciting any sensation beyond the vibration which is communicated to the soft parts. When, however, its organized softer tissue is in a condition of heightened vascularity, bone becomes exceedingly sensitive. We have all experienced the deep-seated, heavy, aching pain, which is consequent on protracted exertion. The common expression "my bones ache," rightly indicates the seat of the sensation. This probably arises from an increased determination of blood to the osseous structures. The "growing pains" of young people are consequent on the increased vascularity attending the increased nutrition. The deep-seated aching pains which occur in the limbs during the cold stage of fever, are produced by a determination of the blood from the surface towards the centre, causing a congestion of the osseous textures.

When, however, bone is in a state of inflammation, it becomes exceedingly sensitive. The swollen vascular fibrous tissue is compressed in the interstices of the unyielding osseous structure; and this circumstance, as in other inflamed parts which are confined, gives rise to the most intense suffering. This pain is of an aching character; dull and heavy, when less intense; acute and throbbing, when more so. It is not constant, but sometimes absent and sometimes severe; without any apparent reason to account for these variations. The following may, however, be considered as causes by which it is affected. Coldness of the general or local surface, by increasing the vascular congestion of the deeper parts, augments the pain, which, on the other hand, is diminished by warmth that causes an opposite effect. All causes, however, which accelerate the circulation, whether heat, mental emotion, or muscular exertion, by increasing the quantity of blood passing through the inflamed part, augments the pain. It is also periodic, showing a disposition to return at particular times, and is more especially severe during the night, circumstances for which it is difficult to account.

THE FUNCTION OF PROTECTION AND REPAIR.

There is a process, very nearly allied to the functions of nutrition and development, which is instituted by nature for the purpose of repairing the effects of injury to the parts of the living body. This function has been absurdly denominated inflammation, and considered as a diseased action of the part, has usually been treated of by the surgeon rather than the physiologist. We cannot, however, regard the function in its natural state, as a disease; but it must, where its actions are excessive, become disease. As the excessive actions of development constitute disease, and the excessive actions of nutrition constitute disease, so the excessive actions of repair constitute disease. The term inflammation should be confined to the excessive actions of the function of repair; for they alone are characterized by its symptoms of redness, pain, heat, and swelling.

In the lowest tribes of the animal kingdom, the function of repair is found in its highest condition. It unites the parts of the halved polype; it develops a head for the decapitated trunk, and a body and limbs, for the head which has been deprived of them; thus converting the divided animal into two distinct individuals. In the insect tribe, it will re-develope a lost antenna, or an amputated limb; whilst in the higher classes of vertebrata, its power is usually confined to the union of incompletely divided parts, and to the perfect regeneration only of some of the less complicated tissues.

FRACTURE OF THE STERNAL END OF THE CLAVICLE.

The clavicle may be, though it very rarely is, fractured at its sternal end. The symptoms which attend this accident are similar to those which attend a dislocation of this extremity of the bone. A young man fell upon his right shoulder and received an injury of this kind; he could move the arm but little, the shoulder was depressed and inclined forwards, the sternal end of the clavicle projected, laying upon the sternum. I, at first, considered this as a case of dislocation, but on a more complete examination, my opinion began to waver, for the extremity felt too sharp for the head of the bone, and it did not cross the median line which I should not have expected from the position of the shoulder. Drawing the shoulder backwards and outwards I fixed my finger on the projecting extremity of the bone. As this receded to its proper situation, I found the head of the clavicle lying in its normal place behind. A gentleman who saw the case with me, at first sight considered it a dislocation, but he afterwards concurred in the opinion that it was a fracture.

Similar difficulties attend the treatment of both

* Continued from page 555.

accidents. It is very easy to reduce the bone to its natural position, but very difficult to retain it there. I found this best effected by combining both the usual modes of treating fractures of the clavicle. The shoulders were drawn backwards by the figure-of-eight bandage, crossing over the back outwards, by a pad in the axilla, and the lower end of the humerus being kept approximated to the side and upwards, by the elbow being well supported in a sling.

DISLOCATION OF THE THUMB.

It is difficult to account for the facility with which a dislocation may sometimes be reduced, which had previously resisted great and powerfully directed efforts. A man came to me from the country, and, holding up his hand, said that the thumb was put out. The dislocation was apparent enough. I grasped the thumb in my hand, and, making slight extension, pressed the head of the first phalanx in a proper direction, and in a second it was in its place. His friend immediately exclaimed, "Surely it cannot be all right; a surgeon in the country has been trying at it this morning with all his might for more than an hour, and he could not succeed." I have no reason to presume that the former efforts had been mis-directed.

INFLAMMATION ONLY OF ONE KIND.

There is probably but one kind of inflammation, and that a local one, arising from a local cause, whilst its modifications and extent depend upon the nature and diffusion of its exciting cause. Where inflammation is extensive, it is so, because the operation of its exciting cause is extensive; where progressive, because the operation of its exciting cause is progressive. If in scarlatina the whole of the mucous membranes and cutaneous coverings are inflamed, it is because the poison, which constitutes this disease, acts locally upon all these paris. When in the care of an envenomed wound, the inflammation extends rapidly into the surrounding texture, it is not because of any peculiarity of the inflammation, but because the action of the poison is progressive, the re-action of the protective function is also progressive.

COLIN ARNECAPLE.

(*To be continued.*)

General Retrospect.

ANATOMY.

NOTE ON ONE OF THE ANOMALIES OF THE RIGHT SUBCLAVIAN ARTERY, WITH ABSENCE OF THE RECURRENT NERVE OF THE RIGHT SIDE.

By Dr. Demarquay, Paris.

Anatomists and surgeons have remarked with great care, all the anomalies of origin and of distribution which the right subclavian artery can present. It is not my object here to record them. I desire only to draw attention to a curious fact which accompanies one of these anomalies; and to speak of the absence of the right recurrent nerve, when the subclavian artery of the same side arises from the left part of the aortic arch, in place of arising from the brachio-cephalic trunk as usual. When the right subclavian artery arises from the left part of the aortic arch, it directs its course to the right side, either by passing in front of the trachea, as Professor Blandin has observed, or behind it, or behind the œsophagus, to restore itself to its normal position. In these various circumstances, he (Professor Blandin,) was curious to know what became of the nerve. Is it alike reflected on the artery, or did this anomaly of origin bring with it a modification in the nerve? This it was which I verified for the first time, in 1843, in a preparation which may be seen in the museum of the school.

In this case the subclavian artery passed from left to right, and after having taken its origin from the left part of the arch of the aorta, passed between the œsophagus and the vertebral column, and thus reached the space between the scaleni. In this case, which has been recorded in Professor Cruveilhier's "Treatise on Anatomy," there was absence of the inferior laryngeal nerve. Since then I have had occasion to examine another subject in which the same arterial peculiarity existed, and where there was alike absence of the recurrent nerve. In these two anomalies, this is the character of the pneumogastric:—it occupies the normal position; from its internal part are given off a great number of nervous filaments, which are distributed to the larynx, to the inferior part of the pharynx, to the trachea, and to the œsophagus. All these nervous filaments, destined to replace the inferior laryngeal nerve, pass under the common carotid artery; some before this vessel, to distribute themselves to the parts which they are destined to innervate. These small nerves which supply the trachea and œsophagus with nervous energy, are on the whole alike in volume to those which normally furnish the recurrent. As for their length and direction, they are a little different, being longer and directed more transversely. The nerves which furnish usually the recurrent to the larynx, come, as in the case which occupies us, from the pneumogastric; this latter affords to the level of the larynx, a branch so volminous, that it might be considered a veritable recurrent nerve; and which arrived at the inferior part of the larynx, is in every respect disposed of in the same way as the termination of inferior laryngeal nerve, a termination so well studied by Professor Blandin. The cardiac nerves furnished ordinarily by the recurrent, are given off by the pneumogastric.

Dr. Demarquay then observes, that in a functional point of view this anomaly is of no moment, justly remarking that in certain operations, as in tying the common carotid, it might occasion great embarrassment to the surgeon, and then concludes as follows:—

Such, then, are four cases where the abnormal origin of the right subclavian brings with it an important modification of the nervous vagus. Are these, then accidental cases, or are they the sign of a phenomenon, always persistive when the subclavian (right) artery arises from the left part of the aortic arch;—and does this induce absence of the recurrent nerve? This I would not venture to say: further observations must prove it.—*Gazette Médicale*, Sept. 9me, 1848.

MALPOSITION OF THE ABDOMINAL VISCERA.

In a case of sudden death, Mr. Robbs found the liver occupying the whole of the left hypochondriac, epigastric, and part of the right hypochondriac regions; the organ was double its natural size. The stomach and spleen were in the right hypochondriac region; the cardiac extremity of the stomach was on the right, and the pyloric extremity on the left. The cæcum and appendix vermiformis were in the left iliac region.—*Medical Gazette*, July 21.

SURGERY.

OPERATION FOR HARE-LIP.

M. Guersant, who has had extensive opportunities of judging of the most favourable period for operating in hare-lip, gives the preference to the period recommended by Dubois, during the first fortnight after birth. He advises against undertaking the operation when the child is about a year old, or during the process of dentition. It may again be performed with much greater hope of success when the child has attained the age of five or six years. Dieffenbach latterly gave a similar preference to the early operation.—*Gaz. des Hôp.*, in *Monthly Journal.*

NEW INSTRUMENT FOR TRACHEOTOMY.

Dr. Marshall Hall has devised an instrument for the performance of this operation, of which the following is a description:—

The instrument consists, first, of a cylinder of steel, of a proper diameter, with its lower edge extremely sharp, as in a gun-punch; it may be either circular or oval. Within this cylinder a piston moves, which may be removed altogether; whilst another cylinder, of which one side overlaps the other, (as in Charrière's speculum,) admits of being compressed, and introduced in its place. This latter cylinder is pushed forward, so as to project beyond the cutting edge of the former, expands, and makes gentle pressure, so as to prevent hæmorrhage; the steel cylinder is then removed. Finally, two-thirds of the inner cylinder allows of being removed, at a part to which a silver disc or shield is attached.

The instrument being placed over the trachea, a portion is detached, and forced into the cylinder as the piston is drawn upwards, and the operation is performed without loss of blood; the silver cylinder being then introduced, it is shortened, and the disc attached.—*Lancet*, September 9th.

[Dr. Hall alludes to Mr. Hilton's trocar as a clumsy instrument, but we think in so doing scarcely does it justice. Complexity is evidently on the side of Dr. Hall's invention.]

NEW METHOD OF TREATMENT IN FISSURE OF THE ANUS.

M. Maisonneuve, believing this affection to depend on spasm of the sphincter ani, has adopted the following operation, (first proposed by M. Recamier,) in order to destroy the spasm by forcible distension:—Introducing two fingers into the rectum, the anus is stretched by drawing the fingers in opposite directions, and the operator is thus enabled to introduce his whole hand into the rectum; he then closes his hand, and draws his fist through the anus. Among a great number of cases the author has not witnessed any bad effects, or a single relapse.

For the complete destruction of the tendency to spasm, the hand must be retained in the rectum for a considerable time; in such cases permanent relaxation of the sphincter is a bad effect to be apprehended from the operation.—*Monthly Journal.*

CURE OF HYDROCELE BY COMPRESSION.

M. Rossi relates the case of a man labouring under hydrocele, who consulted him after he had been punctured several times. A perfect cure was obtained by compression of the tunica vaginalis, by means of a sheet of lead applied on each side of the scrotum precaution being taken not to interfere with the cord or testicle.—*Annali Universali.*

VERTICAL DISLOCATION OF THE PATELLA.

M. Debrou relates the twelfth instance of this rare accident. It happened to a man of 60, who got his leg entangled in a cart wheel; when raised he could not stand upright. His appearance was as follows:—The knee was flexed to within a third of a right angle; extension incomplete, and painful; the anterior aspect of the joint very prominent, on account of the new situation of the patella, which, moreover, was immoveable. M. Debrou reduced it in the following manner:—One assistant holding the thigh, another held the leg and raised the heel, so as to extend it upon the thigh, which was flexed upon the pelvis. M. Debrou standing on the exterior of the leg, supporting the posterior aspect of the joint with the left arm, forcibly pushed the patella inwards with the palm of the right hand; the bone, after a continued effort, slipped into its place.

In speaking of the entire number of these cases, M. Debrou observed that seven were vertical external, (the anterior surface of the patella turned inwards,) and five vertical internal, (the anterior surface turned outwards.) In these twelve cases, reduction has been difficult or impossible in five cases; in four only was the reduction easy. Amongst the difficult cases, three had been produced by external violence acting directly on the patella. In the medium cases, two were owing to external causes, and four to muscular effort. In reducing the dislocation, the choice lies between the method of Valentin and that of Coze; or the manner advised by Mr. Herbert Mayo, and re-introduced by Malgaigne. These methods rest upon theories directly opposed to each other, for the first is based upon the slackening of the muscles connected with the patella, and the other upon their tension. The obstacles to the vertical reduction are:—1. The tension of the tendons inserted into the patella,—viz., the tendon of the quadriceps above, and the ligamentum patellæ below. 2. The sinking of the border of the patella into the superior condyloid depression. 3. The tension of the partly-torn capsular ligament. M. Debrou examines these causes in succession, and without denying the force of the second, believes that its operation is exaggerated, and the tension of the lacerated capsule has

the chief influence in rendering the reduction difficult.—*Lancet.*

TOXICOLOGY.

EVIDENCES OF POISONING BY PRUSSIC ACID.

Dr. W. Wright, of M'Gill College, British America, deduces the following inferences upon the different points connected with the above subject:—

I. *As to the State of the Eyes.*—1. That there is no constant state of the eyes. 2. That the eye-balls are generally prominent, glistening, and bright; pupils dilated, and more or less insensible.

II. *State of the Countenance.*—1. The countenance may retain its natural appearance. 2. It may be pale and calm, as in sleep. 3. It may be livid, turgid, and distorted, with foam issuing from the mouth. 4. That this state is analogous to that observed in epilepsy, while the immediately preceding resembles asphyxia from carbonic acid.

III. *State of the Respiration.*—1. Respiration is variously affected, and may be (*a*) noiseless and tranquil, as in sleep; (*b*) one or two gasps or inspirations; (*c*) noisy and stertorous; (*d*) convulsive and catching; (*e*) slow and laborious. 2. That restoratives cause deep inspirations. 3. That, owing to the above discrepancies, we cannot predict with certainty, that any specific change will be induced in the respiration by prussic acid.

IV. *State of the Pulse.*—1. That our knowledge of the effects of a fatal dose of prussic acid on the pulse is very imperfect, all that can be said is that it renders the pulse imperceptible.

V. *Consciousness.*—1. After a fatal dose, consciousness, reason, and intelligence, are retained for an interval of variable duration. 2. That this interval is usually short, and is succeeded by complete insensibility. 3. That the absence of delirium and mental hallucination are negative characteristics.

VI. *Acts of Volition.*—1. That a person after taking a fatal dose of prussic acid may retain, for a period, command over the voluntary muscles, sufficient to perform various and complicated actions. 2. That the duration of this period cannot be fixed. 3. That the powers of speech may not be immediately annihilated by a fatal dose, and it is not unlikely that they may be enjoyed as long as power and command over the voluntary muscles, generally, are maintained. 4. That, as in one instance, a rational answer was spoken by the victim, to a question three minutes after he had swallowed the fatal dose, so, *a fortiori*, the period, during which consciousness, volition, and motion are exertible, might be, possibly, of three minutes duration. 5. That, with this knowledge, we should be prepared to make allowances for the fulfilment of different intricate performances, in the interval of consciousness and muscular control, which follows the taking of poison. 6. Convulsions occurred in none of the cases cited above, it is, therefore, erroneous to connect them exclusively with those of slow death, or with those where subjects enjoyed more or less muscular control prior to death.

VII. *Of Sensation.*—That, with loss of consciousness, there is also loss of sensation. 2. Prior to the occurrence of which, it is not unlikely that the feelings are not of a disagreeable nature. 3. That prussic acid produces some particular effects on the special senses, as great bitterness of taste, and loud ringing in the ears. 4. That should restoratives be successful, sensation returns, accompanied with feelings more or less perverted, and varying from those of slight uneasiness to those of great agony. 5. That the property which prussic acid possesses of obliterating sensation, classes it among the anæsthetic agents.

VIII. *Of Motion.*—1. That the most important varieties of involuntary motion, observable after fatal doses of prussic acid have been swallowed, are—first, tonic spasm or tetanic rigidity; and, secondly, clonic spasms or convulsions, (epilepsy.) 2. That probably the tonic result from a major dose and greater susceptibility; and the clonic from a minor dose and less susceptibility. 3. That both, more especially from a maximum dose, may be absent. 4. That death is least rapid in cases of convulsions. 5. That convulsions may be succeeded by rigidity. 6. That rigidity may occur without convulsions, and that it usually appears on the departure of convulsions. 7. That the absence of convulsions is denoted by placidity of the countenance, non-clenching of the hands, natural posture, want of derangement of the clothes, and other marks of struggling. 8. The results from experiments on animals as regards convulsions, are not to be expected in the human subject, in whom convulsions are not constant but occasional symptoms.

IX. *Of the Odour.*—1. That the odour is not always present in the breath in cases of poisoning by prussic acid. 2. That if present, it may be questionable from—first, its weakness, which may be due to many causes; secondly, its being masked by other odours; and thirdly, from discords in the opinions of those testing it.

X. *Of the Shriek.*—1. That in man the absence of the shriek is the rule, its presence the exception. 2. It is not improbable that loud gasping inspirations have been mistaken for it. 3. That when it does occur, it is most likely a simple expression of terror, wherefore it might be present only in homicidal or accidental cases. 4. That it would be likely to occur in cases of epilepsy and convulsions.

XI. *The evacuation of the Rectum and Bladder* is an accidental, rather than an essential symptom.—*British American Journal*, August, 1848.

CHLOROFORM IN CHOLERA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR

The singular success which has attended the internal use of chloroform in two cases of spasmodic cholera, occurring in my practice, under the care of my assistant, Mr. Brady, induces me to request you will give publicity to the fact, by inserting it in your Journal. The two cases to which I allude have been already published by Mr. Brady, in the *Medical Times* of August 12th, and September 16th. One of these I saw immediately after, and during the exhibition of, the chloroform;

he other occurred during my temporary absence from ome. In the case I saw, the cramps of the extremities nd abdominal muscles were so severe, that the individual could not lie still to undergo the necessary riction and applications; and the entire absence of ulse, together with the collapsed condition of the atient, forbad for the moment the smallest hope of ecovery. The almost immediate effect of the chloroform was to allay the cramps, to restore the circulation, nd, as a consequence, to diffuse general warmth; and vithout a figure, I may truly assert, the patient was escued from the very jaws of death. I have no wish o claim for the chloroform more than it deserves; but think, with a disease confessedly without its antidote, nd now at our very doors, it cannot be too extensively nown, that in at least two cases in my own practice, nd in three others recorded since the publication of Mr. Brady's case, the internal exhibition of chloroform ossesses the valuable property of allaying the cramps nd vomiting, in spasmodic cholera, and of diffusing eneral warmth, by restoring the circulation, which is lmost a sure precursor of recovery. The *modus perandi* of the remedy is fully and ably treated by Mr. Brady, in his published cases, and to him is due he merit of having first observed its invaluable properties in so formidable a disease.

If you deem the above observations of sufficient nterest, I shall be obliged by an early insertion in our Journal.

I am, Sir, Your obedient servant,

THOMAS HEWLETT.

Harrow, October 10, 1848.

THE TAXIS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In corroboration of the opinion of Mr. Hunt, that 'the taxis carefully and patiently applied will generally succeed in reducing a strangulated hernia," I beg to state that in an extensive general practice of forty years, during thirty-three of which I filled the situation of Senior Surgeon to the Bridgwater Infirmary, I have never had occasion to perform the operation but once, and then in a case of congenital hernia. I believe I have met with the average number of cases, and have frequently been called into consultation with others when the operation was considered necessary. The taxis has been so successful that I have rarely had recourse to bleeding, and never to the tobacco glyster. I have often employed the warm bath advantageously, and particularly in one case which I despaired of reducing, and went home (a distance of three miles,) for my instruments, leaving my patient in a warm bath, under the care of my assistant. I was detained by an accident which occurred immediately on my return before my own house, for more than an hour, and when I reached my patient, I found him still in the bath, (full two hours having elapsed since he was placed in it,) nearly parboiled, but not very faint, and on removing him, the hernia was returned with very little trouble.

I remain, Sir, Yours truly,

JONATHAN TOOGOOD.

Medical Intelligence.

THE CHOLERA.

The cholera has, within the last few days, made its appearance in this country in several districts. Cases are stated to have occurred at Hull, Sunderland, Edinburgh, Woolwich, and in several parts of the metropolis. It is questionable, however, whether many of the cases which have been reported are genuine instances of the disease.

On the Continent, in Egypt, and in Asia Minor, there is reason to hope that it is generally on the decline. It still, however, rages with intensity in some parts of Syria.

MEDICAL REFORM.

The new Council of the National Institute of Medicine, Surgery, and Midwifery, held their first meeting on Wednesday, September 13th. It was very numerously attended, and much satisfaction was expressed at the prospect afforded of an early settlement of the question of Medical Reform, by the general agreement come to at the recent conferences at the College of Physicians, by the delegates from the various medical corporations of Great Britain and Ireland and the National Institute. A report, containing copies of the important documents recently issued by the Conference Committee, has just been published by the Council, which will doubtless be read with much interest by all classes of medical men.

BURIAL CLUBS.

Mr. Tidd Pratt, in a letter to the *Times* says:—"That, by the late Friendly Society Act, 9 and 10 Victoria, chap. 27, sec. 1, it is expressly provided, 'That no person under the age of six shall be allowed to become a member of a Friendly Society for money payable on death, and that no insurance shall be effected on the life of any child under six years of age.' Any Society, therefore, which effects such an insurance after the 3rd of July, 1846, is acting illegally, and the officers are liable to be indicted; in addition to which the money payable on the death of such child is not recoverable."—*Medical Times.*

APPOINTMENT.

The Queen has been pleased to appoint Thomas Southwood Smith, M.D., to be the Medical Member of the General Board of Health.

UNIVERSITY COLLEGE, LONDON.

Dr. Charles J. B. Williams, has announced his intention of resigning the Professorship of Medicine at this Institution, at the close of the present Course of Lectures.

UNIVERSITY OF CAMBRIDGE.

The Degree of Bachelor of Medicine has been conferred on Henry Goode, Esq., of Pembroke College.

ROYAL COLLEGE OF PHYSICIANS.

The following gentlemen were admitted Licentiates of the Royal College of Physicians, on Saturday, September 30th:—William John Fitton, Upper Harley Street; Charles Bland Radcliffe, Queen Square, Bloomsbury; William Addison, Great Malvern; Alfred Swaine Taylor, F.R.S., Lecturer on Medical Jurisprudence, &c., in Guy's Hospital.

William Slyman, of Newtown, Montgomeryshire, was admitted an Extra-Licentiate of the College on the same day.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, October 6th:—J. A. Tapson; J. Laity; J. G. Lymes; J. O. Fletcher; C. E. B. Danson; T. Whitehead; W. Cox; W. Pattison; R. Barnwell.

Messrs. J. Hunter and T. E. Mouldsworth passed their examinations for Naval Surgeons.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, September 14th:—J. Wilmshurst, Reading; Walter Garslang, Clitheroe; James Parker, Aughton, Lancashire; James Thomas Jackson, Ulverstone; William Prowse, Bristol; John Jones Merriman, Kensington; William England, Dudley.

Thursday, September 21st:—Edwin James Hebers, London; Francis David Mudd, Gedding, Suffolk.

Thursday, September 28th:—Richard Thomason, Shiffnall; Henry Hooper; Henry Davies, Holloway; Charles Miles, Charterhouse.

Thursday, October 5th:—William Strong Browne, Camberwell; Matthew Lynch, Liverpool; William Tindall Robertson, Green Hill, Lincolnshire.

OBITUARY.

Died, September 2nd, at Nevis, in the West Indies, W. T. Nicholson, M.D.

September 16th, at Beckenham, aged 49, William Merrick, Esq., Surgeon.

September 27th, at Chichester, aged 27, Edward Miller, Esq., Surgeon, late of Shanklin, Isle of Wight.

October 2nd, at Rye, aged 46, Francis Henry Wilson, Esq., Surgeon.

October 7th, aged 34, Richard Hicks, Esq., Surgeon, Argyle Square, King's Cross.

October 8th, in Great Surrey Street, Blackfriars, aged 84, Robert Mayhew Thompson, Esq., late Surgeon to the 14th Light Dragoons.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

VOLUME OF TRANSACTIONS: NOTICE TO MEMBERS.

The First Part of the Sixteenth Volume of the Transactions of the Provincial Medical and Surgical Association is now ready for distribution to the Members. Gentlemen who have not yet paid their subscriptions for the current year, or who are otherwise in arrear, are requested to bear in mind that the "Transactions" can only be sent to those Members whose subscriptions are paid up.

ROBERT J. N. STREETEN, Secretary.

TO CORRESPONDENTS.

Communications have been received from Dr. Oke; Mr. Cowan; Dr. Collins; Mr. E. T. Roe; Mr. Bartrum; Mr. Hewlett; Dr. Toogood; Mr. H. Stubbs.

Dr. Wardell's request shall be attended to.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

RETROSPECTIVE ADDRESS.

Delivered at the Seventh Anniversary of the

READING PATHOLOGICAL SOCIETY,

JUNE 21st, 1848.

By CHARLES VINES, Esq., Surgeon,

II.—DISEASES OF THE RESPIRATORY ORGANS.—*Croup.*

III.—DISEASES OF THE CIRCULATING SYSTEM.—*Angina—Hydropericardium—Steatosis of the Heart—Fibrinous Concretion of the Heart.—*

IV.—DISEASES OF THE DIGESTIVE SYSTEM.—*Tumour of the Liver—Certain Morbid Conditions of the Epigastric Region—Congenital Contraction of the Intestines—Sub-peritoneal Abscess—Enlarged Spleen—Cirrhosis of the Liver.*

V.—DISEASES OF THE REPRODUCTIVE SYSTEM.—*Miscarriage—Morbid Placenta with Dead Fœtus—Abortion—Large Ovarian Cyst—Puerperal Metritis.*

VI.—DISEASES OF THE URINARY SYSTEM.—*Albuminuria—Absence of Kidney—Calculi.*

IX.—SURGICAL DISEASES.—*Pistol-shot Wound—Hernia—Dislocation of Spine—Fractured Vertebra—Cicatrix from Burn.*

II.—DISEASES OF THE RESPIRATORY SYSTEM.

From the nervous we pass on to the diseases of the respiratory system. On the 19th January, 1848, Mr. May presented the larynx and trachea of a boy, aged four and a half, who died with symptoms of croup. The rima glottidis was extremely small; mucous and sub-mucous tissues engorged and vascular; a slight ulceration within the glottis, and the opening blocked up with a small firm muco-purulent mass. The inflammation did not extend below the larynx; duration of the disease, two days. The treatment consisted of caustics, local bleeding, tartarized antimony, calomel and hot fomentations. Tracheotomy was considered, but not performed, in accordance with the prevailing medical opinion in this country. Mr. May remarked, that though in croup the inflammation generally involved the trachea and bronchi, more or less, it might be limited to the opening of the glottis, and that this case shewed the necessity of a most accurate diagnosis. In future cases, unless there existed positive evidence that the trachea and bronchi were involved, he would take the chance of laryngotomy. It was clear that an opening in the wind-pipe would have given a probability of preserving life, while the local disease was submitted to the curative influence of remedies. It was also obvious that an opening through the cricothyroid membrane would have been as efficient as one made through the trachea.

III.—DISEASES OF THE CIRCULATING SYSTEM.

Angina.—The first case in this class of diseases was related by Dr. Wells, on the same evening. P. H., a porter, aged 65, was admitted at the Dispensary December 29th, 1847. He stated that three months ago, while driving a chaise, he was seized with a violent pain across the chest. The pain was so severe, as to oblige him to go home and remain in bed for some days. Subsequently he got about again, but the pain did not leave the chest, was aggravated at intervals, and accompanied with dyspnœa. For the relief of this condition, he applied at the Dispensary. His pulse was very irregular and intermittent, with a fluttering action of the heart, but the first and second sounds perfectly distinct and normal. There was no œdema of the lower limbs; his chief complaint was the paroxysms of severe pain across the sternum, and the dyspnœa. He expired suddenly on the evening of January 7th, after an attack of pain and dyspnœa more violent than usual.

The *post-mortem* appearances were as follows:—Left lung entirely bound down by old adhesions of the pleura. In the right pleural cavity was a large quantity of serum; the pericardial sac also contained a sero-sanguinolent fluid; patches of thickened membrane upon the external convexity of the heart; the cavities somewhat dilated; valves quite healthy; coronary arteries both ossified, the left being converted into a bony tube. There were several cartilaginous deposits in the aorta. In one of these was an aneurism, passing through the internal coat. Dr. Wells added that this was not a true case of angina; in angina the intermissions are perfect, whereas in this case they were incomplete.

Hydropericardium.—On February 16th, Dr. Cowan related the case of a woman, which was taken into the Royal Berkshire Hospital as one of emergency, suffering from great dyspnœa, respirations 30 in a minute,

extreme faintness, feeble pulse, leading to the supposition that there was great impediment to the heart's action, which was regular, though depressed. Temperature low; great prostration; irritable stomach and bowels; slight œdema. The diagnosis was, that there was pericardial effusion, which prevented the free action of the heart. There was no bronchial sound, no cough, no bellows or friction-sound over the heart; but there was greater dulness over a larger surface than the natural limits of the precordial region; the effused fluid being serous. She had been exposed to wet, and had had rheumatism. Her condition was so depressed that active measures could not be employed, and her stomach and bowels so irritable, that mercury in any shape could not be tolerated, vomiting and serous diarrhœa immediately following. The hot-air bath, and dry cupping over the chest, were the chief remedies, and wine, with other nourishment, was ordered. Blisters and sinapisms had not the slightest effect, the heat of the surface being so depressed; they never act when the temperature of the skin is very low. Morphine was given at night, with great benefit, and she gradually, though unexpectedly, recovered.

Steatosis of the Heart.—On the 22nd March, 1848, Mr. Harrinson exhibited a specimen of steatosis, or fatty degeneration of the heart. The history of the case is as follows:—On the evening of the 28th of February, Mr. P., after having been engaged in his business all day, suddenly fell down on the floor, and expired. Mr. Harrinson saw him a few minutes afterwards. His face was extremely pallid; no frothy fluid was issuing from his mouth; he was 67 years of age, tall, moderately stout, but pale and flabby; he had always enjoyed good health till within the last two days, when he complained of an oppression and pain in the precordial region.

Post-mortem examination thirty-three hours after death.—Thoracic and abdominal parietes loaded with fat; lungs healthy; the heart was soft and flaccid, of a dirty, pale, yellow colour, and appeared one mass of fat; a fatty transformation or infiltration of the muscular substance so soft, that it could be moulded like putty; the ventricular walls thin, and the left cavity dilated; the investing pericardium was raised in various places, by air vesicles and fatty fluid, which streamed down the scalpel; valves and endocardium healthy; coronary arteries normal; auricles and large vessels gorged with blood.

Mr. Harrinson made some remarks on the two varietes of the disease, and referred for a full account of this affection to an excellent paper by Mr. R. Smith, published in the *Dublin Journal*, July, 1836; and to Hasse's "Pathological Anatomy," by Dr. Swain, in one of the Volumes of the "Sydenham Society."

Fibrinous Concretion of the Heart.—On the 19th of April, 1848, Mr. Harrinson presented a specimen of diseased heart, taken from a patient, who, having previously enjoyed pretty good health, began to complain of debility, lassitude, and obscure chest symptoms. Suddenly he was attacked with extreme difficulty of breathing; the skin greatly congested; blue from head to foot; surface cold; pulse scarcely to be felt; heart beating rapidly, and rather forcibly; orthopnœa; cough; expectoration of viscid mucus mixed with blood;—*not* hæmoptysis. Crepitation was heard at various points, and percussion was dull. He gradually sank.

Autopsy sixteen hours after death. General surface still dingy; about a pint of straw-coloured fluid in each pleural cavity; the lungs gorged with black fluid blood; the heart filled the pericardial bag; right auricle enormously distended with blood, the ventricle comparatively empty; left cavities distended with black blood and fibrinous deposit. The auricle was hypertrophied, and almost filled with a mass of vegetation, nearly closing the auriculo-ventricular opening, only a small orifice remaining posteriorly. The vegetations were made up of large granules, intimately adherent with each other, and connected with the auricular surface of the valves, forming a solid vascular nucleus. The ventricular surface of the valves was perfectly free. Liver large and gorged.

On examining the fungus, it appeared to be more a fibrinous deposit than any vegetation from the valves, for the serous membrane of the valves elsewhere did not exhibit any trace of inflammation, and it was probably deposited there on some unknown nucleus.

IV.—Diseases of the Digestive System.

From the diseases of the circulatory we come to those of the digestive system:—

Hepatic Tumour.—On the 25th of August, 1847, Mr. Harrinson presented a tumour taken from Mrs. N., aged 40, who had been married 20 years,—no children. He read the details of her case, which were those chiefly of chronic hepatic and dyspeptic disease. On inspection after death, there was found disease of the heart and liver, effusion into the pleuræ and peritoneum, disease of the ovaries; and this tumour, the size of a small melon, was found on the superior and posterior surface of the liver, (of the right lobe,) intimately connected with it, but easily detached. It appeared to have a large vessel connecting it with the hepatic ducts, and seemed to be filled with mucus and inspissated bile. On opening it in the presence of the Society, it appeared to contain some laminæ of lymph or mucus, and the lining membrane presented some spiculæ of bone. The question arose, what was the tumour? Some thought it a biliary cyst, or supplemental gall-bladder, or analagous to those cysts which form on the kidney. Mr. Harrinson was of opinion that it was an aneurism of one of the hepatic ducts.

Morbid Conditions of the Epigastrium.—On the 20th of October, 1847, Mr. Walford read a paper on certain morbid conditions of the epigastric region, in which he ably upheld the views of Dr. Wilson Philip, on the importance of a due and perfect discharge of the functions of the liver, in the healthy economy of the system, and the value of their early correction, in those disposed to phthisical disease.

In confirmation of these opinions, Mr. Walford referred to cases which had occurred in his own practice, in which he believed that the development of that treacherous malady phthisis, had been prevented by a due regulation of the digestive functions. There can

be no doubt that prophylactic measures are of the highest importance, in the treatment of cases predisposed, either to consumption, scrofula, or any of the disorders of an hereditary or specific type. The prevention of phthisis would indeed confer a boon on mankind; but anxious as we are for the accomplishment of this object, the fatal prevalence of the disease seems at present to bid defiance to the very best efforts of the healing art.

Congenital Contraction of the Intestines.—On the 22nd of December, 1847, Mr. Harrinson presented the intestines of a newly-born infant. The case was similar to one presented at a former meeting, published in Dr. Wells' Retrospective Address, and taken from the second child of the same mother. The infant, shortly after birth, began to suffer from vomiting and constipation, which the usual remedies failed to relieve. The rectum was found to be pervious only to the extent of three or four inches. The child died on the tenth day. On examination after death, the upper portion of the intestines was found distended with air and meconium. The greater part of the ileum was a mere cord; the cæcum was filled with a hard substance; the colon and rectum were cords with a small bead of black matter here and there. The last portion of the rectum was empty. The other organs were quite healthy.

Sub-peritoneal Abscess.—On the 19th of January, 1848, in conjunction with Mr. Waldron, (joint attendant on the case,) Mr. May presented a portion of liver in illustration of acute circumscribed sub-peritoneal abscess, which had occurred in a lady aged 61. She had rigors, pain in the right hypochondrium, with vomiting, restlessness, dyspnœa, pyrexia, and prostration. A tumour of considerable size was felt in the part affected. She was extremely corpulent and of hepatic aspect. The symptoms were relieved by local bleeding, mercury, opiates, hydrocyanic acid, and hot soothing applications to the part, and she seemed to be progressing favourably until the day before her death, when the pulse became rapid and feeble, the restlessness increased, and she sank rapidly, the mode of death being asthenia and syncope.

A *post-mortem* examination disclosed a considerable quantity of sero-purulent fluid in the cavity of the abdomen, which had escaped during life from the cysts of an abscess formed in the convex and right portion of the liver. The abscess was entirely sub-peritoneal. The surface of the liver was black, and apparently disorganized at the site of the abscess, but was healthy in all other respects. The gall-bladder contained several calculi. Heart and lungs healthy, with the exception of a little congestion in the right base.

Enlarged Spleen.—On the 19th of January, 1848, Mr. Walford exhibited an enormous spleen, taken from W. O., aged 64, who died December 28th, 1847. He had been ill six weeks with erysipelas, and for some days before death had bronchitis of the right lung.

Post-mortem examination twenty-four hours after death.—Old pleuritic adesions; the air-tubes of the right lung filled with muco-purulent matter and frothy fluid; left lung sound; heart small, but sound. The spleen was found enormously enlarged, extending to the pubes, and over to the right of the mesial line; it was hepatized, and its weight not less than five pounds; the liver also was much enlarged, its weight not less than seven pounds, and its structure softer than normal; gall-bladder healthy; stomach and alimentary canal not examined; left kidney healthy; in the right was impacted a large calculus.

The cause of the enlargement of the liver and spleen is not clear, probably hereditary. He never had ague, nor had he been in a hot climate. Two years ago he considered himself perfectly well. He suffered severely at times with symptoms of renal calculi, the attacks were followed by the excretion of lithic acid.

On the morning of the day on which he died, he had taken from a chemist some aperient pills, which, acting powerfully, induced faintness, and was the cause of Mr. Walford being sent for, who found him dying.

During life his gait and mode of speaking clearly showed impeded action of the diaphragm. His walk was slow and cautious.

Cirrhosis of the Liver.—On the 19th April, 1848, Mr. Harrinson related a case of cirrhosis of the liver, and made some highly valuable and interesting remarks on that disease.

In January, 1848, Mr. Harrinson commenced attending a publican, aged 55, who for many years had been addicted to drinking. He had been remarkably strong and healthy, but latterly subject to cough, with expectoration; his countenance sallow and cachectic; he was liable to fits of hysterical convulsions,—and it was on one of these occasions that Mr. Harrinson first attended him. An attack of influenza succeeded, and a train of symptoms next followed, in which hepatic derangement, ascites, and anasarca of the lower limbs were prominent. Dr. Cowan attended the case in conjunction with Mr. Harrinson, and the remedies employed were mercurials, elaterium, opium, blisters to the abdomen, with a nourishing and supporting diet. His strength, however, gradually failed, petechia and purpura took place, the legs ulcerated, and, at the end of two months, the patient died.

Post-mortem examination 29 hours after death:—Head not examined. Right lung healthy, but compressed to the spine with bloody fluid, amounting to many pints; the left lung remarkably spongy and voluminous, though gorged with fluid; heart healthy; the pericardium contained bloody fluid. The abdominal parietes were lined, and viscera bound down by, thickened peritoneum, red, shining like velvet; the gall-bladder was small, and contained a little bile; the liver smaller than natural, and on incision presented a yellowish white appearance; little nodules appeared elevated from the cut surface, the nodules were yellowish, the interstices greyish; the right kidney smaller, whiter, and firmer, than natural; the left larger than natural, congested; spleen small and softish.

Mr. Harrinson alluded to the lengthened period (twenty days,) this patient had taken mercury without producing the usual effect on the gums, attributable primarily to the portal contamination; secondarily, to the congested state of the intestines.

Mr. Harrinson also made some interesting remarks on the pathology of cirrhosis, and described minutely its insidious and fatal effects on the system at large.

V.—Diseases of the Reproductive System.

Miscarriage, followed by Convulsions.—On the 20th of October, 1847, Dr. Cowan related the case of a lady, who, after suffering from miscarriage, induced by a fright, was affected with violent epilepsy, hemiplegia on the right side, and loss of speech. She was partially conscious, with a staring eye, and most violent action of the carotids. During the fits the paralysed side moved. On examination after death, the longitudinal sinus was found distended with coagulated blood, and all the small veins leading into it were filled as if with injection, as was also the right lateral sinus; the left lateral sinus was empty; there was also disease of the anterior parts of the brain. The case was most like phlebitis of the veins of the brain, if such condition could occur. As no examination of the other parts of the body was allowed, it was impossible to say what was the state of the uterus, liver, or lungs.

Your reporter said that he had now a case where erysipelas of the head and face followed upon abortion. The concomitant symptoms were a rapid pulse, and fœtid vaginal discharge. The remedies were directed to relieve the puerperal condition, and the patient speedily convalesced.

Mr. May strongly advocated the practice of injecting the uterus and vagina with warm water in puerperal cases. When there is a quick pulse, tender abdomen, and fœtid vaginal discharge, he always resorts to this plan of practice.

Morbid Placenta, with Dead Fœtus.—On the 24th of November, 1847, Mr. Harrinson presented a specimen of a morbid placenta, with dead fœtus. A lady, aged 23, married in May. Symptoms of pregnancy went on till after quickening, when all signs of it began to decline. At the end of six months a thick gelatinous red discharge took place, which continued for a fortnight, after which pains came on, and the present specimen was expelled. The whole mass of the placenta was diseased. Mr. Harrinson had no doubt that the disease of the placenta was the cause of the death of the fœtus. Cases of this description are often involved in much doubt and obscurity, syphilis, mercury, scrofula, and debility, having each in turn been assigned as the morbific cause.

Large Ovarian Cyst.—On February 16th, 1848, Dr. Woodhouse presented a large ovarian cyst, which appeared to arise from the right ovary, and to be involved in the broad ligament, the Fallopian tube being much enlarged, and extended seven or eight inches, adhering to its side. In the wall of the sac were two or three small cysts containing fluid, and the interior presented projections of membrane, which seemed to be boundaries of smaller cells, which had burst and become merged into the larger one. Thirty-eight pints of limpid serum were drawn off. Dr. Woodhouse considered this an instance of what Dr. Bright calls the simple, sessile, non-malignant, ovarian tumour. The patient dated its origin from a miscarriage, about twelve months before her death, but a more minute enquiry from her friends rendered it highly probable that she laboured under the disease years before.

Puerperal Metritis.—On the 16th of February, 1848, Mr. Walford read an interesting case of a lady, who, after delivery of her second child, went on very well for the first two or three days, when tenderness of the hypogastrium, quickness of pulse, and slight fœtor of the lochia came on, which, not yielding to tepid injections and purging, was relieved by the abstraction of twenty ounces of blood. He considered the inflammatory symptoms to be uterine. Two days after, the liver was found to be enlarged, and had this discovery been made earlier, a judicious mode of treatment might have prevented the occurrences which succeeded the labour.

Mr. Walford made some practical observations on the effects which a diseased and congested state of the liver and spleen is likely to have on the system, through inability to receive the diverted current of blood after the uterus contracts.

Following up the same line of reasoning, we may conclude, *cæteris paribus*, that the cessation of the catemenial period will prove far more critical, and perhaps fatal in its effects, in those cases where the liver has been previously diseased.

VI.—Diseases of the Urinary System.

Albuminuria.—On the 25th of August, 1847, Dr. Cowan mentioned the delails of a case recently under treatment. A gentleman, after repeated attacks of gout, became comatose, with scanty urine, though the skin was moist. On testing, the urine was found to be albuminous, and of low specific gravity, which led to the diagnosis that there was induration of the kidney, with a deficient secretion of urea, and the coma in consequence. A copious secretion from the bowels relieved the system, and the patient recovered, but will probably have another attack. The diagnosis turned entirely on the examination of the urine, without which the case would not have been clearly understood.

Absence of Kidney.—On the same evening, Mr. Harrinson read the following history of a case:—A man, aged 50, traveller to a wine-merchant, was treated for a fortnight for pleurisy of the right side. The dyspnœa was very urgent, and he gradually sank. On a *post-mortem* examination, there was found acute pleuritis of the right side, with copious albuminous effusion; also intense pericarditis, with solid deposit and sero-purulent fluid; lungs healthy, but compressed; liver hard, irregular on the surface, cirrhosed; left kidney large, lobulated, and much mottled; right kidney absent, only a mass of cellular membrane found in its place; urine found in the bladder highly albuminous. The disease of the kidney no doubt disposed to the inflammation, and made it more intractable.

Calculus.—On the 16th of February, 1848, Mr. Walford presented a large calculus of lithic acid, taken from the right kidney of a patient from whom he had removed the large spleen exhibited at the last meeting.

Mr. Dunn also presented a calculus, taken from a patient in the hospital, by Mr. Maurice, (weight, one

ounce and ten grains,) consisting of lithic acid, with a coating of oxalate of lime.

VII.—Fever.

Typhus.—There is but little to introduce to the Society on the subject of fever: one isolated case only stands recorded. On the 22nd of March, 1848, Mr. F. Bulley was called to a case of typhus fever, which he treated in part on hydropathic principles, and the patient recovered. Dr. Cowan made some valuable remarks on the cold-water system. He thought that the advantages of hydropathy were much exaggerated, and that the cures attributed to this system, might fairly be traced to the change of air, scene, and other circumstances into which the patient was thrown, and in fact, that the cold water had but little to do with the success of the treatment.

VIII.—Malignant Diseases.

Several interesting cases of malignant disease having occurred during the year, I have thought it better to arrange them under a distinct head.

Cancerous Tumour in the Posterior Mediastinum.—On the 19th of April, 1848, Dr. Cowan mentioned the case of a female, aged 56, plethoric, rather healthy in appearance, who was admitted into hospital on the 11th of March. Her complaint commenced with a dry hacking cough. Puffiness of the face, hands, and neck, had been noticed for the last six weeks. She had sickness, with regurgitation of food when coughing. On admission, she exhibited a congested state of the jugular veins, without pulsation; heart regular in action; no œdema of feet and legs; intense bronchial character of the respiration between the shoulders; parenchyma and lungs healthy. The only sign of disease was obstruction of the circulation in the heart, increased by decubitus. Two views might be taken of this case: either there was aneurism; or some tumour in the posterior mediastinum, pressing on the veins. Temporary relief was afforded by cupping and other remedies. She was seized on the 15th with greater difficulty of breathing and fainting, from which she was rallied by stimulants, but died on the 17th. On a *post-mortem* examination, a tumour of a malignant character was found arising from the bronchial glands, passing down to the right side of the trachea, pressing on the œsophagus behind the heart, compressing the vena cava superior, and taking the course of the right bronchus, through the base of the right lung and diaphragm, into the liver. The liver below and the lungs above were intimately adherent to the diaphragm, which had also degenerated into the same kind of morbid structure. Dr. Cowan founded his diagnosis on the peculiar respiration heard between the shoulders at the base of the lungs.

This was the fourth case of malignant disease in the posterior mediastinum which had occurred in his practice, and they all presented nearly the same symptoms.

Scirrhus of the Œsophagus.—On the same evening Mr. May presented a case of malignant disease of the œsophagus, which occurred in a female aged 68. The complaint began four months ago, with difficulty of deglutition. The case was so well marked as to preclude any curative attempt. Temporary relief was afforded by blisters. About three weeks before her death, she complained of dyspnœa, which gradually increased till death took place by apnœa. The autopsy discovered a mass of scirrhous deposit in the upper portion of the œsophagus behind the larynx.

Scirrhus of the Liver.—Dr. Cowan mentioned another case of malignant disease, in a woman who had been out of health about two years. Three weeks before death, her medical attendant noticed a tumour of the liver, which appeared to be of a malignant character. Neither dropsy nor jaundice were present, nor any other symptom but the general characteristic condition of the system. The *post-mortem* examination discovered a large scirrhous tumour of the liver. The great value of the diagnosis in these cases is the determination of the line of treatment necessary to be pursued, and the abandonment of all useless remedies.

IX.—Surgical Diseases.

The last class of cases I have to record are the surgical or accidental.

Pistol-shot Wound.—On the 25th of August, 1847, your reporter presented a specimen of bone, taken from the skull of Mrs. C., who eight years ago was wounded in the eye by a pistol-shot. She came under treatment some months since, suffering from great debility and general derangement of health, and an acrid discharge from the right eye. She died at the end of July. On examination after death, the eye was found collapsed, the brain softened, and the optic nerve wasted. There was a slight projection of bone into the middle fossa of the base of the skull, to which the brain and membrane were adherent. The ball was found lodged in the ala major of the sphenoid bone, just beneath the projection into the middle fossa, above referred to. Your reporter read the early history of the case, as given by Dr. Walker, who attended her at the time of the injury, which gave interesting details of this extraordinary case, and explained the doubts and difficulty of ascertaing the true position of the ball, although the impression was that the ball was lodged within the cranium. This case excited some public interest at the time, for the pistol was fired by the husband of the unfortunate woman, and it became the subject of a judicial enquiry at the Abingdon assizes. The man was transported, and owed his life to the doubt as to the pistol containing a ball or not.

Hernia.—On the 22nd December, 1847, your reporter related the case of a female, who ten years ago was admitted into St. Mary's Infirmary, with umbilical hernia, which had latterly increased to an enormous size. She had suffered at various times from symptoms of strangulation, but had lately died from an attack of bronchitis. On a *post-mortem* examination, a large fibrous tumour was found proceeding from the left ovary; this occupied the pelvis, and passed upwards into the abdominal cavity; the intestines were protruded at the umbilical opening, in a large irregular mass; the ascending and transverse colon, with the whole of the small intestines, were contained in the hernial tumour, which was enveloped by peritoneum, thickened in some

parts to the extent of a quarter of an inch, and like fibro-cartilage.

Dislocation of the Spine.—On the 16th February, 1848, Mr. Dunn presented, what he considered to be, a dislocation of the spine, between the last cervical and first dorsal vertebræ, in a young man aged 22, who was caught by the smock-frock, and dragged into a thrashing mill. It seemed to be a laceration of the intervertebral substance, but there did not appear to be any fracture of the articulatory surfaces. Mr. Dunn considered this to be a case of pure dislocation of the spine, though this is denied by most writers.

On the same evening Mr. Shoreland related the case of a soldier, who in a state of partial intoxication slipped from a verandah, ten feet high, but caught by his hands when falling, which gave a jerk to the spine, and fractured the fourth dorsal vertebra. He was taken to the hospital, where he remained till next morning without shewing any signs of paralysis, and he was not minutely examined, it being supposed at the time that it was merely a contusion from the fall. Whilst sitting up in bed and taking his breakfast the next morning, he was observed to have fallen forwards, and on the orderly raising him up, he was found quite dead. On inspection after death the spine was found dislocated, with fracture of the bone. Sitting-up produced a displacement, and fatal pressure on the cord was the consequence.

Operation for Cicatrix.—On the 19th of April, 1848, Mr. May presented Charlotte Taylor, a hospital patient, whom he introduced to the Society on a former occasion, and who had undergone the operation of a section of the skin under the chin, which was drawn down by the cicatrix of an old burn. The girl happening to be in town, called to show herself, and prove the great and satisfactory results of the operation, by which the deformity is nearly obliterated, and there is no appearrance of a return of the contraction.

I have now, gentlemen, completed the history of the transactions of our Society during the past year, and though we cannot boast of much that is novel or striking in what has been brought forward, yet, we may safely say that there has been much that is practical and useful.

Let us not relax for one moment in our efforts to advance the standard, and promote the usefulness of our profession. If we can add but one mite to the treasury of medical knowledge, we shall have performed a duty to our fellow creatures, and created a feeling of satisfaction in our own consciences. It is by the interchange of ideas,—by the aggregation and association of talent, that we may hope to increase our professional knowledge, and societies like ours are well calculated to effect this object.

Before concluding this address, I would express the thanks of the Society to Mr. Dunn, for his kindness in undertaking the care of the museum.

I thank you, gentlemen, for your kind and patient attention to this prolonged, and I fear, somewhat tedious address.

OBSERVATIONS ON CHOLERA.

By Charles Cowan, M.D., Physician to the Royal Berkshire Hospital.

(Read before the Provincial Medical and Surgical Association, at the Anniversary Meeting, held at Bath, August 16th and 17th, 1848.)

At the present moment, the following non-professional experience on the all-engrossing subject of cholera, drawn up by Lieutenant General Welsh, of the Madras army, a true Christian philanthropist, and a sound observer, will not, I feel sure, be unacceptable. Such evidence has, at all events, the advantage of being free from professional bias, while it essentially confirms the conclusions of the majority of medical writers, as to the cause, progress, treatment, and non-contagious character, of this terrible disease. It has also the strong recommendation that the means so diligently employed were attended with more than ordinary success. To the best of General Welsh's recollection, he thinks that the deaths did not exceed five or six in a hundred, while many medical men were losing from a fourth to one half of their cases. He attributes the favourable result in his own practice to the power of wholly devoting himself and servants to the prompt application of the remedies, and to never abandoning their vigorous employment until life was extinct; and under circumstances similar to those which now threaten us, we must be indebted to reported results more than to theory, for our therapeutics.

Notwithstanding all that has been written, (and it is legion,) we are wholly ignorant of the essential cause of cholera, and our treatment must therefore, necessarily, to a certain extent, be empirical. On the other hand, it is impossible to doubt, that means of the most opposite class have, in numerous instances, proved efficient, and out of the vast mass of information now accumulated, each practitioner must select those processes of cure most congenial to his judgment, and most sanctioned by success. Hence the importance of collecting the experience of individual observers, that some approach to soundness of inference may be secured, from the very extent, if not from the accuracy, of the materials.

The neutralizing power of large numbers over minor discrepancies is well-known, and, on a similar principle, from vague, though widely concurrent, testimony, many valuable practical indications may be deduced. This idea is now receiving a very apt illustration in the pages of our useful and greatly improved Journal, on the important question of the treatment of burns, and we think a similar concentration of experience on the therapeutics of cholera, would equally elicit some interesting results, and greatly tend to settle the general line of practice most prudent to adopt.

Judging from the long ages which have elapsed, there is but little reason to anticipate that we shall ever become familiar with any of the specific causes of

epidemic diseases, but our increasing acquaintance with the conditions favourable to their production, extension, and intensity, fully justifies the assertion, that by wise sanitary arrangements, their frequency, prevalence, and fatality, may be materially curtailed. It is, therefore, to Sanitary Reform rather than to medical interference, that the attention of Government and of the profession, should be chiefly directed, and until vast changes are accomplished in our present most imperfect and injurious social conditions, the best-directed efforts of medical science will fail to preserve the population of this or any other country from being largely victimised by epidemic visitations.

"No more striking exemplification can be afforded of man's short-sightedness, and of the difficulty in carrying out the most self-evident improvements, whenever any present sacrifice is to be made, prejudices relinquished, or old habits overcome, than the coldness and opposition experienced by those who are so meritoriously devoting themselves to this truly practical and important question; and from such an experience how easy is it to understand the obstacles which have ever impeded the progress of a purer speculative truth, where facts of such a purely sensual and self-evident character are greeted with so unwilling—so imperfect a response! But to return to our author:—

"The first appearance of this dire and inexplicable pestilence, says General Welsh, took place in the year 1817, when it broke out suddenly in Bengal, and made particular havoc in the town of Calcutta, and among the shipping in the river Hoogly; from thence, apparently travelling in a western direction, over an immense tract of country, with high mountains, and other apparent obstacles intervening, it made its way to Bombay, and then down the whole Malabar coast. It afterwards appeared to reascend the mountainous Ghauts, which separate the sea-coast from the interior of the Peninsula, passed through the Mysore into the Carnatic, where its ravages spread terror and dismay in every direction; visiting, in the whole route, the lowest grounds, with the keenest severity, but generally losing its force at each place where it rested, after a few weeks continuance. In some places it completely thinned the inhabitants, but its attacks were mostly confined to travellers and poor people, living in low, damp, and swampy spots; and in many cases, an immediate removal from such situations to high ground, even in the very neighbourhood, has arrested the spreading evil, and even restored the afflicted individual to health.

"In the years 1819 and 1820, it appeared to be at its height, and generally spread all over India; and the strongest proof of its being confined to low ground is the fact, that in the Mysore country, while thousands were attacked and perished at Seringapatam, (a low island formed by the junction of two rivers,) it never reached Bangalore, the largest and highest military cantonment in the Peninsula; and in the same degree it was felt at Calcutta, and on the Malabar coast, while the higher civil and military stations of Tellicherry, Cannanore, and Mangalore, were comparatively free.

"I do not assert a total exemption in any place, because the seeds of the disease may be sown at a distance, and only break out on arriving at a healthy station, and possibly then spreading by contagion; but after raging for two or three years, and in too many instances baffling all the attention of man, its virulence gradually abated, and latterly only extended to corps and bodies of men on the march, who were naturally more exposed to the night air, and subject to the baneful influence of every kind of malaria.

"*Symptoms.*—The symptoms of this disease are so various, and in many cases so resembling others of a different nature, that it defies all regular description. The most common are as follows:—

"It commences with a degree of stupor, diarrhœa, and general lassitude, and a painful sensation of heat and fulness in the stomach and chest. Vomiting follows, at first producing undigested food, afterwards an occasional discharge, more or less copious, of watery, whitish, or discoloured and fœtid liquid, which passes in many cases involuntarily, both up and down; an immediate prostration of strength; a pulse rapidly decreasing until it is entirely lost; a total suppression of urine; the extremities becoming cold and covered with a clammy moisture; great thirst and restlessness, with violent contortions in some, and lethargic inanimation in others; the eyes glazed and sunk in the head; skin shrivelled, and in short, the whole appearance of a healthy youth of 17 or 18 turned suddenly to that of decrepid old age. This is the most common kind, and it is the easiest cured if taken in time.

"There is another in which few, if any evacuations take place, but in addition to the early symptoms of the first, the whole frame suffers a rigid contraction of the muscles, with the eyes as it were starting out of their sockets. But the worst form of all, within my observation, is one in which the patient rapidly sinks without a struggle, and if not timely relieved, expires in the course of two or three hours. The termination of the first is usually within twenty-four hours; that of the second in a half or even a fourth of that time; but in all, the remedies must take effect in a few hours, or they are almost invariably hopeless, though they should never be relaxed or abandoned, till life is positively extinct.

"*Causes.*—The predisposing causes in the human frame, are generally considered to be a paucity or total absence of bile in the stomach, a derangement of the digestive organs, and poverty of blood, arising most likely from impure air, and unwholesome aliment; but I have also found, in many cases, a subsequent indication of a very different cause, and wherever it has occurred, the patient has by diligent perseverance in the means, under God's blessing, invariably recovered.

"It has generally taken place after all the alarming symptoms of the first form have been exhibited, and the treatment apparently ineffectual, when suddenly a large worm, eight or ten inches long, has been discharged by the mouth, and the patient, overcome with the exertion, has sunk into a death-like stupor. Then, and then only, have I administered nourishing cordials, particularly port-wine, of which a wine-glass was given every half-hour, until returning animation proclaimed a happy rescue from the jaws of death. The circumstance now mentioned was not commonly known among the medical men with whom I was acquainted in India, which may easily be accounted for, when it is

considered that no surgeon there could give his entire and undivided time to any patient, or even to two or three. Whereas, in the years 1818-19 and 20, I happened to be comparatively idle, holding an independent staff-situation, and having my whole family in England, I was consequently enabled to give my whole time and attention, day and night, to such poor natives as were taken ill in my immediate neighbourhood, and with my own servants to assist me, could watch the whole progress of the disease, and observe the effects of every application in each of my patients.

"My practice and experience were chiefly among the lower orders on the Malabar coast, mostly at Calicut in those years, and afterwards among small parties of native troops and followers attendant on myself and family. In other parts of the Peninsula there were always experienced medical men present, with whom I would not, of course, presume to interfere.

"*Contagion.*—At that time no one ever suspected that the disorder was infectious, and fortunate indeed was this for thousands, whose lives were preserved through the willing attendance of their family and friends, and who would otherwise have been inhumanly abandoned to their fate; and notwithstanding the now too-generally received impression, that it is contagious, I still feel inclined to question that opinion, unless where the predisposing causes exist.

"Though an invalid, subject to constant attacks of bile, liver, and indigestion, I have attended many patients at once, both in my own house, and in the lowest and most miserable situations, where it has been raging all around us with fatal effect, yet neither myself, nor any of my servants (about ten in number,) who all cheerfully assisted me, ever had a symptom of the disease; and if I might venture to explain the idea I have formed of the progress of this almost universal scourge—this severe visitation of God, I would call it an epidemic, contained in a quantity of impure miasm floating in the air, and more particularly attracted by low, damp, and filthy spots, in which a certain degree of miasm may always be supposed to reside.

"*Treatment.*—If the patient is young or middle aged, vigorous and sanguineous, and no medical aid at hand, a vein should be opened, and twenty or thirty ounces of blood taken, to insure which, the blood in most cases becoming dark and stagnant, it is necessary, after the incision, to rub the arm, and put the feet in hot water, (if a hot bath cannot be procured,) as well as to administer and continue warm antispasmodic draughts, with warm frictions, and applying hot substances to the body and extremities, of which a very simple and efficacious one is sand, heated in a pan over a fire, and put into small linen bags or old stockings, and kept in contact with the hands and feet, stomach and spine; no quantity of liquid to be given, and nothing cold, particularly water, for which the patient usually has an incessant craving. Warm gruel is, perhaps, the best vehicle for everything.

"Various stimulating medicines have been tried by different people, with pretty nearly the same effect; and I have at times, when travelling, and nothing else was at hand, given essence of ginger, brandy, laudanum, peppermint, &c.; but where all the articles could be procured, I would recommend, (always and only in the absence of medical aid,) in addition to an immediate warm bath, half an ounce of the following mixture, more or less frequently, in a little warm gruel:—Opium, dr. j.; Camphor, dr. j.; Ginger, dr. j. Cardamoms, dr. j.; Capsicums, dr. iss.; Arrack or Brandy, oz. viij. M. To be infused for seven days.

"If this be not prepared, half a glass of brandy, with forty or sixty drops of laudanum, and twenty or thirty drops of essence of peppermint, may be substituted; or twenty grains of camphor, or from a tea to a dessert-spoonful of essence of ginger, either dose to be repeated every half hour or oftener, if not retained on the stomach, till a favourable change becomes visible. Warm enemas have proved beneficial, especially when the retching continued and the draughts were returned, and in one instance succeeded, when all hopes by other means were at an end. Calomel in large doses was used by the faculty in India, and succesfully I believe; but I never had an opportunity of trying it, because there was not any to be purchased during the first two or three years of the pestilence.

"*Signs of Cure.*—The first indications of amendment, where the blood has been originally congealed, are,—its becoming limpid, and flowing freely, a return of the pulse, of warmth in the body, of softness and pliability in the skin, and falling into an easy slumber; but the most certain prognostic of a cure is the free passage of urine. A sleep of some hours succeeds, and the patient generally awakens to convalescence; I say generally, for in the course of my experience some few apparently relieved fell into a quiet slumber, from which they only awoke to breathe their last sigh, or expired without awaking at all.

"*After-Treatment.*—As soon as the first attack has been got over, a large dose of castor oil should be given, or a strong bolus of calomel and opium, and after its operation, if no fever should intervene, the patient should be warmly clad, and nourished with cordials and plain wholesome food, in small quantities, but particularly avoid all fruit, vegetables, or cold draughts, for some considerable time, as every relapse is attended with the utmost danger."

In conclusion, our author remarks, "as nothing is so conducive to illness, particularly the one in question, as terror or alarm, I would earnestly recommend to all my fellow-creatures to place a cheerful reliance on the all-sufficient protection of a long suffering and ever gracious Redeemer, and to be prepared, by a life of faith and consequent usefulness, for whatever may befal them."

The preceding observations, though couched in non-professional language, embrace within a brief compass the chief points in the experience of our most practical writers, and are highly creditable to the zeal, the intelligence, and the philanthropy of the writer. They strongly point out the protective value of sanitary arrangements,—the greater prevalence and intensity of cholera in undrained, low, and damp situations,—the striking exemption of higher localities,—and the great advantages of removing the sick from the scene of infection.

On these main indications, confirmed as they are by widely convergent testimony, should all our prophylactic measures be based; and it is deeply to be regretted, that the army of selfish impediments which have hitherto obstructed the progress of sanitary measures,

must in the present instance render impossible, more than very imperfect and almost futile attempts at their accomplishment, arrived as we now are, at the eve of a closely impending visitation.

It is not by quarantine regulations,—it is not by boards of health,—it is not by printed circulars of directions,—it is not by skilful medicinal combinations, that we shall ever materially control the spread or the mortality of this or of any other epidemic; but by fundamental social improvements, which long years alone can effect, and which a truly enlightened and philanthropic government, backed by an intelligent population, can alone carry out.

Had our noble profession, on all matters relating to the public health, that prominency assigned to it to which it is so justly entitled, the chariot-wheels of Sanitary Reform would not have lingered as they have done; and to the untiring energies, generous efforts, and scientific acquirements of many among our ranks, are we now indebted for those dawning hopes of future improvement, which we may, perhaps, at length, justly venture to entertain.

On the much-contested and important question of the contagion of cholera, the conclusions of the writer are also consonant with those of the majority of practical observers; and during my own close contact with the disease in Paris, for about three months, in 1832, where it prevailed more intensely than in any other capital of Europe, the whole of my experience was decidedly adverse to the idea of contagion. I would not assert that cholera is never contagious, nor advise unnecessary communications with the sick; but judging from what I personally observed, that the disease is very rarely, if ever, so communicated, and that the epidemic influence is all-important for its propagation, I cannot for a moment doubt.

As a confirmatory instance I may mention, that the great corn granary of Paris was converted into a temporary cholera hospital of one thousand beds, and to this a staff of twenty physicians and sixty students was attached. Now, though the whole of our time was devoted to the infected, taking our meals and sleeping two nights a week in the hospital, not to mention almost numberless *post-mortem* investigations, I do not recollect that a single medical officer, student, or even nurse, caught the disease. My own health was remarkably good; and it was not till having relinquished all active exertions, and at the very close of the epidemic, that I was personally a sufferer.

Of the fatal influence of fear and despondency I witnessed very striking examples in two newly appointed hospital physicians; and of the powerful agency of hope, I was myself an instance; for being lifted on the outside of a diligence, to return to England, under circumstances considered most hazardous if not hopeless by my friends, a ride of a few hours, under God's blessing restored me to comparative health.

With reference to treatment I have nothing to communicate founded upon the results of my own practice, nor have I the time on the present occasion, to give, as I intended, a digest of the many plans which have been recently recommended. But as a large proportion of the practitioners of this country are in similar circumstances to my own, viz., pensioners upon the experience of others, I may mention, that the result of my gleanings from the various treatments that are recorded, is in favour of the combined employment of those measures to which active efficiency can be fairly attributed, being guided in their individual application by the general principles of medical art.

On the great importance of attending to *the early symptoms*, and especially to the initiatory diarrhœa, all observers strongly and unitedly insist, that against this stage of the disease, too much care and promptness cannot be employed. In the early period of collapse, in robust plethoric individuals, there is much evidence in favour of bleeding. A stimulating emetic when the first vomiting is imperfect, followed by a full dose of calomel and opium, more or less frequently repeated with the unlimited use of effervescing salines, or in their absence, of cold water, with stimulants internally and externally, especially the latter, in proportion to the collapse, and regulated by the feelings of the patient, form the leading features of the plan I should feel most disposed to adopt, while I doubt not many cases would occur, where nothing should at first be attempted but the most energetic application of warmth and stimulants.

As to a host of smaller remedies, to which great virtues are attached, their employment should never interfere with the more rational and intelligible indications, and I believe that our success in the management of this most urgent and formidable disease, will be proportionate to our little confidence in specifics, and our steadily carrying out, independently of name or theory, the leading principles of our art. In addition to the above suggestions, I would remark, that it is highly worthy of experiment how far packing with blankets in a cold or warm wet sheet, at the commencement of collapse, or even after its establishment, would tend to induce reaction, and allay the cramps and restlessness more rapidly than any other plan, while under circumstances where this is opposed, the spirit-vapour, and hot-air bath, would most effectually contribute to the same result. It is also a point of some practical value to consider whether, in many cases, the effervescing salines, or cold water, might not be replaced by unlimited drinks of beef-tea, salted or spiced, cold or warm, as preferred, containing, as it does, most of the elements so quickly drained off by the diarrhœa.

Before concluding this very brief outline of our subject we would merely observe, that the main and immediate indications of treatment appear to be the

shortening of the duration, and the diminishing of the intensity of the collapse, restraining the discharges, and supplying at the same time the elements which are so rapidly removed. Warmth, stimulants, and diluents, we therefore regard as the leading therapeutical agents, and should classify opium, calomel, acetate of lead, petroleum, croton oil, &c., as among the more or less useful adjuvants. It cannot be too often repeated, that the success of all rational treatment will be in proportion to its prompt and early application.

Of the essential cause, and true nature of cholera, we shall not attempt their elucidation, satisfied that nothing is easier or more delusive than to mould our facts to our fancied explanations, and to multiply words without knowledge.

We again admit ourselves to be amongst the number of the wholly ignorant on both these fundamental points, and as yet to have thanklessly rejected all efforts at enlightenment. What the future may develop it is not in our power to divine, but judging from the past and the present, no one similarly constituted to the writer will feel surprise, if his expectations are not very sanguine.

[The following letter has been communicated by Dr. Cowan as an appendix to his paper.]

Henley, September, 1848.

My dear Sir,—Agreeably to your request, I have committed to paper a brief account of the inroad of cholera into this neighbourhood in 1832. The singular progress of this scourge from India to Europe on a former occasion, when, after ravaging Jessore in 1818, it attacked the crew of the *Warren Hastings* and other East Indian vessels in the Bay of Bengal. Spreading over China, after reaching Canton in October, 1820, it extended itself through Persia in 1823, re-appearing in the autumn for several successive years in the same localities. In the spring of 1830 it showed itself for the second time in Astracan, diffused itself over Russia, reaching Moscow in September, Warsaw in April, 1831, and subsequently Archangel, Riga, and this country in 1832. The similarity of its present course has arrested the attention of medical men, and made them anxious to be prepared to meet this formidable disease with the most active and efficient remedies. I am not aware that I can add anything new in the treatment of this malady, but having attended forty-one cases, I most willingly give the result of my own experience.

In September, 1832, I was called to attend several severe cases of diarrhœa, putting on the well-known symptoms of cholera, attended with severe vomiting and purging of rice-water or "congee" stools, violent cramps in the legs, weak and irregular pulse, blue appearance of the nails and lips, livid hue of the body, corrugated skin of the hands, suppression of urine, impatience of being covered up by the bed-clothes, although the skin was cold, and the body covered with a clammy moisture, these symptoms proving rapidly fatal within twenty-four hours, unless speedily relieved by the most active treatment.

The first case occurred in Henley on the 9th of September, in the lowest and dampest part of the town, and proved fatal in twenty-four hours. Six days elapsed before another case occurred, but on the ten following days, fourteen persons living in the same locality were seized with it, four of whom died. In October there were only two cases, one of which proved fatal. On the 3rd of November it re-appeared with additional violence in the upper and high part of the town, but from the experience I had had in the treatment of the former cases, few now proved fatal. The last case was registered on the 12th of December, when the disease took its departure from Henley.

In all, forty-one persons were attacked, eight of whom perished, and five of these fatal cases occurred amongst those that were first attacked, and they had been treated with stimulants,—brandy, æther, ammonia, and calomel and opium. Finding this plan did not succeed so well as I could wish, I treated my subsequent patients, when called in at the commencement of the attack, and the case admitted of it, with one full bleeding, and administered an emetic, with ipecacuanha and calomel, and gave calomel and opium every hour after, with as much cold water as the person desired to drink, and afterwards supported the strength of the patient with broth, gruel, wine, &c. I will report one case to illustrate my plan of treatment.

Ann Martin, aged 14, a delicate girl, was seized at two o'clock a.m., (the usual period of attack,) on the 9th of November, with the symptoms of cholera. She took a full dose of ipecacuanha and calomel directly, then calomel and opium every hour after, and as she complained of great thirst and burning heat at the epigastrium, I ordered a bucket of cold water to be placed by her bed-side, and she was desired to drink as much as she pleased. Every ten to twenty minutes she called for half a pint of cold water, drank it hastily, and lay down quiet for a short time, but as soon as it became warm in her stomach, she vomited it up with violence, in fact spouting it half across the bed-room; she immediately would call for more cold water, which always afforded her relief, this being in a short time ejected in a similar manner. During the first twelve hours she drank between two and three gallons, the second night not a quart, and she afterwards gradually recovered from the subsequent fever with salines and a nourishing diet. The great prostration of strength that follows these attacks requires great attention to diet, and to avoid exposure to cold, to prevent relapses.

I will conclude by relating a case of cholera arising from breathing foul air, which may help to throw some light on the origin and causes of this mysterious and singular disease.

Mr. Knight, of Nettlebed, aged 35, a mason by trade, previously healthy, was employed to clean out the mud and sediment of a rain-water tank; this was done without any previous ventilation, and occupied him several hours. Whilst at work he did not observe any very offensive effluvia. This was on Tuesday, the 13th of June, 1837. Two days afterwards, on Thursday the 15th, I was sent for to see him at 6, a.m.; he had been seized during the night with vomiting and purging, violent cramps, and all the symptoms of cholera. He was bled, took calomel and opium every hour, with salines, had mustard sinapisms applied to the abdomen, and warm frictions over the body, but he died the next day before two o'clock, thirty hours after I first saw him, and seventy-six after inhaling the foul air of the tank. His own expression was, "that his blood was poisoned."

The similarity of the symptoms to my former cases of cholera forcibly struck me at the time, and led me to suppose that inhaling the exhalations of the many stagnant pools and decaying vegetable matter in the old water-tanks of India, was very frequently the cause of cholera in the low swampy districts of that country.

Apologising for this hasty sketch,

I remain, my dear Sir,

Yours very truly,

T. W. JESTON.

CASE OF PURPURA HÆMORRHAGICA.

By E. T. Roe, M.D., Plymouth.

Maria B., housemaid, aged 30, of healthy appearance, slightly above the middle height, of fair complexion, brown hair and eyes, osseous system largely developed, the bones of the hand especially being unusually large for a female, even in her station.

She states that she is a twin, that her father and mother are living and well, and that all her family, consistlng of one sister and six brothers, are strong and robust. Her state of health has been generally good, but she has suffered occasionally from a feeling of sinking at the pit of the stomach, and from flatulence and sick headache. She only recollects having had one serious illness in her life, and that was a fever, many years ago.

Six weeks before her present attack, she observed a blackness around one knee, and she suffered also from a severe "cold on the chest." The discoloration continued for a fortnight, and was ascribed to kneeling.

On the evening of the 27th of June she retired to bed as well as usual, and slept soundly. On rising the following morning, she observed some bruises and marks in the right infra-clavicular region, which she showed to her mistress, laughingly remarking that her fellow servant had pinched and treated her very badly during the night. She felt well, but was very properly ordered to obtain medical advice, and on my seeing her she presented the following appearances:—

An ecchymosis under the right clavicle of about an inch square, surrounded by a few petechiæ; no spots elsewhere, except inside the lower lip. She is cheerful, and says there is nothing the matter with her. Pulse 100, soft, and presenting no peculiar feature; heart's impulse powerful; sounds normal. Says she has always had palpitation, but never been prevented doing her work by it. Urine natural; bowels regular; motions healthy. She has taken nothing unusual to eat, and the most searching enquiry fails to detect any cause for the onset of the malady.

I ordered her a turpentine mixture, and a smart purgative. Lemonade as ordinary drink.

29th. The ecchymosis on the right side the same as yesterday, but petechiæ have appeared on the left and over the legs and trunk; none on the arms. Blood oozes from the inner part of the lower lip. She was sent to bed and ordered a mixture consisting of Dec. Matico, Potassæ Chloras, and Ol. Terebinth., every two hours.

30th. The bleeding continues from the lower lip, and this morning has commenced to issue from the left nostril. The whole body is covered with ecchymoses, petechiæ, and vibices; the most extensive extravasations being on the lower jaw, and on the inner part of the left thigh immediately above the knee. She is in no pain, appears cheerful, and desires to be allowed to get up, as she thinks she shall soon be well again. Pulse 110, jerking; tongue slightly coated and reddened by the blood which has passed down her throat; urine dark and evidently contained blood; motions black, grumous, resembling coffee grounds, but more fluid.

I plugged the nose with matico and ordered lemonade to be taken in large quantity. To be allowed wine, beef-tea, and oranges, and to continue the same medicine.

July 1st, 8 a.m. Decidedly worse, countenance exsanguined, features pinched and anxious; pulse 120, feeble and jerking; slight cough; tongue thickly coated, dark. The hæmorrhage from the nose is profuse, and large quantities of blood have from time to time been swallowed, which now makes her feel sick; she vomited several times and brought up much blackish blood; the lips are bleeding; the urine is of inky blackness; and throws down a heavy black deposit on standing; the evacuations from the bowels are black fluid blood, without smell or any other evidence of containing fæculent matter. More petechiæ have made their appearance over the body.

I plugged the nostrils with matico, and ordered ammonia and catechu.

1 p.m. Worse; features pinched; eyes half closed; jactitation; frequent sighing; deadly faintness; surface of body cold and clammy; tongue thickly coated, black, and would be dry but that she is obliged constantly to wash her mouth out, to discharge the clots at the back of the pharynx. On looking into the mouth, the blood could be seen passing steadily down the œsophagus. Pulse 140 to 150, reduced to a thread. She has lost all hope. Death, indeed, appeared inevitable, and an hour or two at the farthest would propably close the terrible scene—a scene which certainly presented as frightful characters as I ever witnessed even in the worst form of Asiatic cholera. The bleeding lips and nose, the shrunken discoloured face, the bruised jaw, the frightfully black excretions, and blood on everything around, looked more like some horrible domestic tragedy than the work of a few brief hours of ravaging disease.

I determined to plug the nostril from behind, by passing a dosssil of lint through the posterior nares, and even while performing this trifling operation, I feared she would die. The tongue and pharynx were cold. Having succeeded in passing the plug through the left nostril, I ordered her a wine-glassful of brandy and the following mixture:—

R. Acidi Gallici, dr. ss.; Tinct. Opii, m. iv., Aquæ, oz. ss., every half hour,—and plugged the right nostril, which, previously to the left having been stopped had not bled much, but from which the blood now flowed in a stream.

9 p.m. Slightly improved; bleeding ceased.

2nd, 5. a.m. No return of the external bleeding.

Pergat. She is improving, but the excretions are still black.

1 p.m. The gallic acid produced vomiting; and effervescing draughts with Sulphate of Magnesia, and Liq. Opii Sed., Battlei, were substituted.

The following day she commenced quinine and acid. The urine was become of natural color, and the motions although still dark had lost their blackness.

5th. The catamenia appeared, and for a few hours assumed an hæmorrhagic character, but were checked by half-grain doses of opium.

17th. She was able to go home, there had been no return, of the hæmorrhage and she was gradually gaining strength; the excretions were healthy, and the spots on her body had nearly disappeared. She was ordered to take quinine, iron, and sulphuric acid, while in the country.

August 15th. She returned to Plymouth, and I then examined into the state of the various organs of the body as exactly as possible with the following results:—The heart is large and powerful, but otherwise healthy. The right lung healthy, with the exception of slight sibilous rales on deep inspiration. In the left the respiratory murmur appears normal upon ordinary inspiration, but when a forced effort to fill the lungs is made, a splashing or gurgling is heard, as if cavities half filled with fluid existed in the lungs, but so circumstanced as to be out of the reach of ordinary breathing. This sound is heard throughout, and not confined to the upper portion of the lung; expiration rather prolonged; resonance clearer on left side than right, and the percussion sound duller; slight uneasiness on pressure in the epigastrium; the hepatic region does not present any enlargement, and the extent of dulness on percussion is perfectly normal; nothing abnormal in the abdomen; urine healthy; tongue furred; pulse 100; no cough nor night perspirations. She was directed to continue her tonic medicine and apply a blister to her right knee, having inflammation of the bursa from kneeling.

30th. She again went into the country.

September 22nd. Returned to Plymouth much improved. She has gained flesh and colour; tongue cleaner; pulse varying from 84 to 96, soft; menstruation regular, but still rather profuse; left lung improved, the splashing heard only in the centre of the lung. She was ordered to continue her medicine, and apply a blister to the left side of the chest, and on October 3rd she went home.

I have dwelt so long on the progress of this case, as to leave little space for speculations as to the cause of the disease, nor do I regret this, for it would tend, I fear, to no satisfactory elucidation of the subject. It has been said that the liver is the organ generally at fault, but here, so far as we may judge by the evidence presented, such was not the case. My valued and talented friend, Dr. Butter, suggested the possibility of the system having been poisoned by the inhalation of the vapours of lead and turpentine, during the progress of painting the outside of the house she was living in at the time of her illness, having seen cases of hæmorrhage from that cause; and it did appear highly feasible that some such poison had been received into her system, by the suddenness and violence of the attack, but subsequent investigation showed that six weeks before her illness, and long before the painting began, a very extensive ecchymosis had made its appearance on one of her knees. The house she lived in is large, and situated as healthily as any in Plymouth. Her situation was light, many servants being kept, and the utmost regularity maintained, so that she was placed in very favourable circumstances for the preservation of health.

The remedy that saved her life was gallic acid, in half-drachm doses, and I would earnestly advise recourse to it at an early period in any similar cases that my professional brethren may be called upon to treat, and trust they will favour us with the results of their experience.

Princess Square, Plymouth,
October 4th, 1848.

CASE OF ACUTE HYDROCEPHALUS: IODINE: CURE.

Communicated by E. Copeman, M.D., Norwich.

W. M., aged 6 years, of scrofulous habit, well but delicately formed, of quick perception and excellent memory, with a remarkable fondness for reading and study, has almost from birth been subject to slight convulsive actions, starting during sleep, and awaking with a scream, but in other respects had enjoyed good health until about the beginning of April, 1847, when he began to lose his appetite, his bowels became deranged, and his sleep more troubled. On the 18th he was attacked with violent purging, which, however, soon ceased, but he became very restless and feverish, and complained of pain and heaviness in the head. For several nights, and frequently in the course of the night, unless constantly watched, he jumped completely out of bed, screaming violently. A purge of Hydrarg. cum Creta and Scammony was given, and acted freely, cold was applied to the head, he was put into a hip-bath, and ordered to take small doses of calomel and antimony, and a mixture of acetate of ammonia.

This treatment was continued for ten days, but his appetite failed, and he became stupid, sitting for hours with his chin upon his breast, and not answering questions unless previously roused by a loud noise, or by shaking him, when he started and appeared frightened, but answered collectedly, although very briefly, and in a peevish tone. He complained of no pain, and was not feverish. Pulse very small and frequent; tongue covered with white fur, but moist. Blisters were applied behind the ears, and at the back of the neck, the calomel and antimony continued, and, as he took no food, and appeared very feeble, a mixture of bark and ammonia was prescribed. The bowels being costive, aperients were from time to time given.

About the 29th he began to complain that he could not see distinctly, and at the same time his speech became

very difficult, so that he could hardly be understood, and his hearing was also greatly affected. In a few days he became quite deaf, to all appearance blind, and when he attempted to speak, which was very seldom, he could not be at all understood. The pupils were widely dilated, and the pulse hardly to be felt at the wrist. While in this state, (about May 2nd,) he was ordered five drops of Lugol's solution of iodine every four hours; two days afterwards he became more sensible, could hear a loud noise, and took food. The iodine was continued, the dose being gradually increased; and he recovered, by degrees, the senses of which he had been deprived, being in better health at the beginning of June than before the attack.

He has remained in good health up to the present time, September, 1848.

LETTER IN REPLY TO DR. COLLINS, ON THE DURATION OF LABOUR AS A CAUSE OF DANGER AND MORTALITY TO THE MOTHER AND INFANT.

By J. Y. Simpson, M.D.,
Professor of Midwifery in the University of Edinburgh.

To Dr. Collins, &c. &c. &c., Dublin.

My Dear Sir,—

A few months ago I took an opportunity of transmitting to you some proofs of the first five or six sections of a "Memoir on Turning, as an Alternative for Craniotomy and the Long Forceps, &c.," publishing in the *Provincial Medical Journal*. In the last No. of that Journal you have, on this subject, published a letter, addressed to me. For your own sake I do sincerely regret that you had not first sent this communication to myself, instead of to the Editor of the Journal, because I should have had pleasure in showing you privately the serious errors of calculation and reasoning which you have committed in it, instead of being compelled, as now, and in self defence, to speak of them openly and publicly.

Let me premise, however, first and once for all, that in writing the fourth section of the memoir,* (the one on which you principally comment,) as in writing all the other sections of it, I have, as far as I am aware, made no remark upon you or upon your work, calculated, in any degree, to call forth a communication from you, conceived and written in such a tone and spirit as your letter betrays. Under various chapters in your treatise, you invite your readers to use your data for further calculations. I have done so, but I have done no more; and I should have felt sorry indeed if I had allowed any word or expression of disrespect to escape from me, of which you or any one could complain. I have quoted, to be sure, and in your own words, some of the interesting cases which you have published of delivery by the crotchet, &c., as cases where, probably, the proposed operation of turning would have been more successful in saving human life. But certainly, in doing this, I no more attached, or dreamt of attaching, any blame to you for not turning in these instances, than I could mean to attach blame to you for not using anæsthesia in your practice twenty years ago, when the practice of anæsthesia in midwifery was unknown.

I have often already stated, and gladly and willingly repeat, that your work is a most admirable collection of obstetric cases and data, and that it would be difficult in this respect to overpraise its candour and worth; but I believe at the same time that the deductions which you yourself have drawn from your data are, in most cases, incorrect. Your data are, I believe, exceedingly accurate and valuable, but your own deductions from these extensive data are, I believe, equally, in most cases, extremely inaccurate and valueless.

For example:—The principal question in debate between us amounts to this. You maintain that the mere protraction of labour is not a material cause of danger to the mother, and, as a consequence, you hold that the mortality from the effects of protracted labour is, to use your own expression, "strikingly small." On the contrary, I maintain and hold, that the mortality arising from the effects of protracted labour is strikingly great. You maintain that your published reports of 16,414 deliveries, which occurred in the Dublin Hospital when you were Master of that Institution, prove that neither the deaths of the mothers, nor the number of obstetric complications, were much or at all increased with the duration of the labour. I maintain that your published reports of these 16,414 cases prove quite the contrary. You maintain that the test of your own recorded "practical experience" shows you to be right in the opinions that you have formed on the preceding points. I maintain that the test of your own recorded practical experience shows you, on the other hand, to be wrong in these opinions,—against, in short, the truth of your own recorded opinions; and to appeal to the truth of your own recorded facts, against your own doctrines, I merely appeal to your own data.

One fundamental mistake in your statistics and calculations has led you into all your numerous errors and inaccuracies relative to the effects arising from the morbid protraction of labour. This error has made you repeatedly express and maintain, as the supposed result of your own facts and experience, opinions which your own facts and experience, when properly interpreted, totally, and altogether contradict.

The error I allude to is this: in calculating from your experience of 16,414 deliveries, the effects upon the maternal mortality of morbid prolongation of the labour, as a special or individual complication, you calculate the resulting number of deaths in relation to the total sum of all the cases delivered, (16,414,) instead of calculating them in relation to the total sum of all the cases merely that were protracted. You calculate the effects of the complications relatively to the whole number of cases of delivery, instead of relatively to the whole number of cases of this special complication, (protraction.) An example may illustrate my meaning. I shall take it from the subject of rupture of the uterus and vagina.

During your seven years' Mastership of the Dublin Hospital, thirty-four cases of rupture of the uterus and vagina occurred, and thirty-two of the mothers died; two only of the thirty-four survived. If asked whether rupture of the uterus were a dangerous complication or not,—whether the mortality attendant upon it was "strikingly small or strikingly great," what answer would you return? If you argued and answered upon this special complication as you do with regard to the special complication of protraction, you would maintain that the mortality from rupture was strikingly small; for only thirty-two mothers out of 16,414, or

* See *Provincial Journal* for February 9, 1848, p. 57.

about one in every 513, died of it. This would shew, certainly, the proportion of deaths from rupture in relation to the total sum of all the cases delivered; but it would not shew what was wanted, viz., the proportion of deaths from rupture in relation to the total sum of all the cases in which rupture happened. If you wished, in short, to state the real risk and danger attendant upon this special complication, (rupture,) you would state that thirty-two mothers died of it out of thirty-four cases in which it occurred, instead of stating that only one in 513 died of it. And, exactly in the same way, if asked what was the degree of maternal risk and danger attendant upon another special complication, viz., protraction of labour beyond twenty hours, your answer upon the same principle should not be as you have it,—forty-two deaths in 16,414 labours, or in the proportion of one in 391; but forty-two deaths in 452 labours, (the *whole* number protracted beyond twenty hours,) or one death in every eleven cases of labour prolonged to this amount of protraction.

Ask any intelligent actuary, or any medical friend acquainted with the principles of statistics, and they will perhaps convince you more than any more lengthened remarks of mine would, respecting the errors you have committed on this, and on various other analagous statistical questions. But I have taken up too much time with these preliminary remarks, and I must hasten on to shew the erroneous nature of the more direct criticisms, which you have pleased to offer on some of the statements and opinions contained in my memoir. The principal of these statements and criticisms I shall answer by a simple appeal to, and tabulation of, your own data; for in these data, as I have already said, there is always contained the best and most complete refutation of your own opinions, I shall notice your principal objections and statements *seriatim*.

1. I have ventured in the fourth section of my "Memoir on Turning," to lay it down as a general law, that "*the maternal mortality attendant upon parturition increases in a ratio progressive with the increased duration of the labour.*"

The law itself—and I believe it to be a most important one—was originally educed by a series of calculations out of your own cases. I formerly published merely the *results* of the calculation, without publishing the *data* on which these results were founded, for my object was not to overload my paper, or the pages of the Journal unnecessarily. As you believe, however, that these results are "obscure," and must be erroneous, because totally opposed to your opinions; and that they consist only of "partial data" and of "visionary" "theoretical calculations," (to quote your own expressions,) I shall simply, in answer to all this criticism, insert, in a tabular form, the data themselves upon which this law and its results were founded.

Out of your 16,414 cases, you noted the duration of the labour in 15,850; and among these 15,850 cases, 138 maternal deaths occurred. The following table contains, in its first column of figures, the total number of deliveries that took place under each specified period of duration; in the second column is stated the corresponding number of deaths occurring among each set of these deliveries; and in the third column is given the proportion which the deaths bear to the whole deliveries in labours of each specified degree of duration. In other words, the table reads thus*:—3,537 mothers had their labours terminated within one hour from their commencement; and of these 3,537 mothers 11 died, or 1 in every 322. The labour continued from 2 to 3 hours in 6,000 cases, and out of these 6000 cases 26 mothers died, or 1 in every 231, and so on.

Table shewing the Proportion of 138 *Maternal Deaths in Relation to the Duration of Labour in* 15,850 *Cases of Delivery recorded by Dr. Collins.*

Duration of Labour.	*Number of Deliveries*	*Number of Deaths.*	*Proportion of Deaths.*
Within 1 hour	3,537	11	1 in 322
From 2 to 3 hours	6,000	26	1 in 231
From 4 to 6 hours	3,875	29	1 in 134
From 7 to 12 hours	1,672	21	1 in 80
From 13 to 24 hours	502	19	1 in 26
From 25 to 36 hours	134	8	1 in 17
Above 36 hours	130	24	1 in 6
Total	15,850	138	1 in 115

I need not, I believe, add a word of comment, for these figures themselves speak strongly enough against your opinions, and in favour of mine. But you must excuse me adding, that the data of the table are not, (as you declare,) "partial." They include all the 15,850 cases in which you noted the duration of the labour. In the remaining 564 cases of your 16,414, you did not note the duration of the labour. But I am not answerable for that omission. And I am sure that your own good feelings will prompt you to withdraw the improper accusation of "founding doctrines upon partial data" from your work.

2.—*Does the Liability to various Morbid Complications during Labour increase in proportion as the Labour is increased in its Duration?*

In one section of my paper I had stated that the above law holds good in regard to most obstetric complications, as puerperal fever, &c., and rupture of the uterus, convulsions, retention of the placenta, &c. You demur to the truth of the law educed, and in your letter to me, you select one complication to refute my views, and make the following statement regarding puerperal fever:—"That this intractable disease," you observe, "is *not* the result of *protracted* labour, as you erroneously state, is notorious to those who have had opportunities of observing it, *and is fully proved in my report*, the total number of cases being eighty-eight, seventy-one of which were delivered within twelve hours, and eighty within twenty-four hours." In your treatise you offered, some years ago, a similar opinion. "It is stated," you remark, "by several writers, that females who have suffered from tedious and fatiguing labours, are particularly liable to puerperal fever. This, you add, *does not accord with my experience.*"

Now, it does accord with your experience. Here, as elsewhere, your own facts and data show that very opinion to be true which you believe to be untrue. The following table is a brief way of expressing these data in reference to the eighty-four cases of puerperal fever, in which the previous duration of the labour was noted by

* The other tables that follow are constructed in the same plan, and read in the same way.

you, and it sufficiently shows that the liability to this (like other complications,) increases as the labour increases in duration:—

Table of Duration of Labour in Eighty-four Cases of Puerperal Fever, in the Dublin Hospital, during Dr. Collins' Mastership.

Duration of Labour.	*Number of Deliveries.*	*Number of Cases.*	*Proportion of Cases.*
Within 6 hours ..	13,412	61	1 in 219
From 7 to 12 hours	1,672	10	1 in 167
Above 12 hours ..	766	13	1 in 59
Total	15,850	84	1 in 186

3. *Does the Infantile Mortality attendant upon Parturition increase in a Ratio progressive with the increased Duration of the Labour?*

I have stated this as another general rule, deducible from your data. You doubt its soundness, and in answer to it express yourself as follows:—"In reply to this theory, I shall only state the simple truth which you have omitted, that of 1,045 cases of still-born children accurately noted, 844 were delivered within twelve hours, and 932 within twenty-four hours; and I have added that the death of the child subsequent to birth, except in very few instances comparatively speaking, was not a consequence of injury arising from protracted labour; for of the 284 which was the total number of deaths, previous to the mother leaving the hospital, the labour in 246 did not exceed twelve hours. These unquestionable facts extinguish all speculative theories."

On this, however, as on other points, against the truth of your opinions and criticisms, I have merely to appeal to your own "unquestionable facts." And I will do so by shewing you in the following table, that my "speculative theory" (as you choose to term it,) is merely a simple generalization of your own experience and cases.

Table shewing the Proportion of Still-births in Reference to the Duration of Labour in 15,850 Cases of Delivery. (Dr. Collins' data.)

Duration of Labour.	*Number of Deliveries.*	*Number of Still-born Children.*	*Proportion of Still-born Children*
Within 2 hours ..	7,050	347	1 in 23
From 3 to 6 hours	6,362	346	1 in 18
From 7 to 12 hours	1,672	151	1 in 11
From 13 to 24 hours	502	88	1 in 6
From 25 to 36 hours	134	42	1 in 3
Above 36 hours ..	130	71	1 in 2
Total	15,850	1,045	1 in 15

The opinion which I have above quoted from your late letter to me, as to protraction of labour not influencing the life of the child *after* its birth, is expressed by you also in your Treatise, (p. 513.) "To prove (you observe) that tedious labour is not often the cause, it will be sufficient to mention, as is clearly shown by the tables, that of the 284 children dead, the labour in 246 instances did not exeeed twelve hours."

If we throw out of these 284 cases, the premature or twin children, as too small in size to be influenced much in their passage during labour, and those born imperfect or diseased, we have 155 children left, born at the full time, and apparently perfect in formation at birth. The following table of these cases will prove to you, contrary to your opinion, that tedious and protracted labour is a cause of death to the child after birth.

Table of Duration of Labour in 155 Deliveries where the Children died within a few Days after Birth. (From Dr. Collins' data.)

Duration of Labour.	*Number of Deliveries.*	*Number of Deaths.*	*Proportion of Deaths.*
Within 6 hours ..	13,412	110	1 in 122
From 7 to 12 hours	1,672	24	1 in 70
Above 12 hours ..	766	21	1 in 36
Total	15,850	155	1 in 102

In the preceding observations I have used no arguments to refute your criticisms and statements, except your own data. Your own figures talk too eloquently against the soundness of your deductions to require any assistance on my part. And here let me observe, that in one sense the term "experience," which you so often repeat, is misapplied by you. A man who watches and reasons upon 50 cases accurately, may form sounder deductions than a man who sees 500 or 5,000 cases, but who watches and reasons upon them inaccurately. And in its last and essential analysis, true experience really consists in true deductions from the cases observed, more than in seeing cases, however numerous, and drawing imperfect or improper deductions from them. Two practitioners of so-called experience, may each see a vast amount of similar cases, and yet, ultimately, draw the most directly opposite conclusions from them. Supposing one of these practitioners right and the other wrong, then certainly, of the latter, the so-called "vague and arbitrary experience, (as Bacon writes it,) astonishes rather than instructs." Dr. Hamilton and you each had an opportunity of seeing a very large amount of obstetric cases, and you each, through thus watching facts or phenomena of exactly the same nature, came ultimately to conclusions exactly opposite in regard to the effects of morbid protraction of labour upon the safety and life of the mother. He came to the conclusion that morbid prolongation of the labour is a great cause of danger and death to the mother. You came to precisely the reverse conclusion, and attacked him with the "strong observations" which you alluded to in your letter to me. The means of settling, and settling statistically and definitely, all, or almost all, the points in dispute between you and Dr. Hamilton, exist in your own work; and when the

evidence of your own data is properly arranged and estimated, it will be found, I believe, as in the foregoing tables and instances, to refute your opinions, and support those of Dr. Hamilton, to a degree which you could scarcely have ever dreamt of. But I feel assured that your own candour of mind, and your deservedly high standing, will enable you to perceive and own this, and so repel the well-known saying of Locke, that, "there are few, if any, men, who once dreadfully mistake, that are willing to be set right."

In your letter to me, besides challenging the truth of the generalizations which I had offered on the duration of labour as affecting the life and safety of the mother and infant, you have entered into other criticisms, and made other observations on my essay. The principal of these criticisms and observations I shall now notice. For instance:—

4. Speaking of the results of your practice when Master for seven years of the Dublin Hospital, and of the number of patients who died of puerperal fever, you observe—

"If we were *only* to deduct the deaths from this fatal disease, which may be considered *accidental*, the entire maternal mortality for seven years would then be less than one in 156. And *why* (you specially ask,) is it not stated that for the four last years of my residence in the Hospital, after puerperal fever disappeared, during which period the very great number (10,785,) of deliveries occurred, fifty-eight only died, or in the proportion of one in 186?" Why? Simply because I had nothing to do with the matter. I should have been travelling altogether out of my road if I had mentioned it. My essay is not, in any, the very slightest degree, a comment upon the good or the bad success of your practice. My calculations and inquiries were altogether independent of the numbers you happened to save or to lose. The principles I have educed would have equally appeared whether your practice had been twice more successful or twice less successful than it was. The proportions you lost at any specified time did not interfere in any respect with my calculations, and I had no interest in the point you allude to.

But since you ask such strange questions, let me ask you one or two in turn. Why is it not stated by *you* that during the first three years of your Mastership, out of 5,629 women delivered, 106 died, or one in every 53? Why have you never mentioned that in one year, (1826,) when you acted in the Hospital partly as Assistant-Physician, and partly as Master, 81 out of 2,440 women delivered, died, or one mother in every thirty-one? Why not add that during five years subsequent to the four which you have named, one woman in about every fifty delivered in the Dublin Hospital, died?

You prominently state, (with what good taste I leave others to decide,) that in 1821 and 1822, in the Edinburgh Lying-in Hospital, when under the late Dr. Hamilton, "1 in 21 of the patients" died. You know that this high mortality arose from the prevalence of puerperal fever, which you deem an accidental complication. Why have you not added this? Why have you not added, that in the Dublin Hospital when the same epidemic prevailed two years before,—viz., during 1819 and 1820, with all the superior endowments and accommodation of that large and rich hospital, the mortality was nearly as great, or about 1 in 34? You state that "unfortunately the above is the only record in existence of the mortality of this public charity"—the Edinburgh Lying-in Hospital. An official report was published, and, I think, certainly transmitted to you, the year after I succeeded Dr. Hamilton, shewing that out of the 930 patients of the Institution, whose deliveries had occurred immediately before and up to the date of the report, only 1 mother had died, (1 in 930,) and that death had occurred in consequence of disease of the heart.

5. But after all, is your selected and highest return of 1 death in 186 mothers, when puerperal fever was not in operation, any great success? You evidently think so. You yourself write with great self-complacency—

"Dr. Collins' practice is *much the most successful on record*, as (there is) no report of 10,785 cases with a mortality nearly so small as 1 in 186." You claim from me that I should publicly state this as "only an act of simple justice to you!" "I feel called upon, (you further observe,) to seek the declaration of this important truth from you;" and you add, "I am induced to request you to blend a more equitable portion of merit to me, as I believe you would not intentionally *pluck the laurel off my brow*, or withhold, what, I hope you will agree with me in thinking, I may from you legitimately claim."

Now, I certainly have no desire to pluck, as you poetically express it, the laurel from your brow. Nor, indeed, is there the slightest fear of myself or any one else doing it; for the truth, I humbly fear, is, there is not any laurel to pluck. Your *selected* return of one maternal death in 186 deliveries is not greater than various other hospital reports shew under the same circumstance,—viz., under the subtraction of all casualties from puerperal fever. In your hospital during your Mastership, 1 in every 100 mothers died, (puerperal fever included;) 1 in 186 when puerperal fever had disappeared. In the Dublin Obstetric Hospital, superintended by Dr. Churchill, 1 mother in 219 died, (puerperal fever included;) 1 only in 274 when puerperal fever deaths were not included. (See *Dublin Quarterly Journal*, Vols. xiii. xv. and xxiii.) In a printed report of the Edinburgh Maternity Hospital now lying before me, 1 in every 134 mothers died, (puerperal fever included;) 1 in every 368, (puerperal fevers not included.) (See *Monthly Journal* for November, 1848.)

But we need not take a return, *selected* either as regards time or as regards the absence of puerperal fever, to shew a success greater than your own. Most of the readers of your letter in the *Provincial Journal*, could, I believe, shew a better return, *without* any selected time or circumstances, than yours, *with* your selected time and circumstances; for in the last year, (1842,) for which the Registrar-General has as yet published no returns of the relative number of births and deaths in childbed, among 517,739 births registered in England and Wales, 2687 mothers perished in childbed, or 1 in every 190 mothers died. Do you object that the average rank of life was higher than among your patients? That objection does not certainly apply to the patients of the London Maternity Charity. Yet out of 35,743 deliveries among the patients of that Institution, only 166 mothers died, or 1 only in every 215.

And please to recollect, too, that the practitioners at the London Maternity Charity, who were thus, without any selection, so much more successful in practice than the Master of the Dublin Hospital with his selections, and to whom, therefore, I fear you must surrender that laurel of which you suppose yourself the wearer:—Please, I say, to recollect, that they are (shall I write it?) female practitioners—real petticoated midwives.

When adducing the supposed success of your own practice, I am not aware that you have anywhere stated that your general success during your seven years Mastership, as far as regards the maternal mortality alone, was considerably less than that of other Masters who had preceded you in the same institution, as Dr. Rock and Dr. Evory. But the accoucheur, in every case of labour, has charge of two lives, the life of the mother and the life of the infant. In your 16,414 cases you had committed to you, for instance, 33,068 lives, including 16,414 mothers, and 16,654 infants, out of these 33,068 lives, one in every twenty-seven was lost, a mortality greater, I believe, than that which had happened to almost any of the other Masters who have had charge of the Dublin Hospital. You choose to blame and criticize me for losing, in my private practice, during a late epidemic of puerperal fever, and when using anæsthetics, two mothers from puerperal fever, out of 150 deliveries. Out of 150 children born in these 150 cases, only one was dead. Of the 300 lives thus entrusted to me, I lost only one in 100; you lost one in twenty-seven.

The statistical investigations of Merriman and Casper have proved, that in England, and upon the Continent, the number of maternal deaths following delivery, has decreased during the last century from about one in fifty or eighty, to one in 150 or 180, from the science and art of midwifery being everywhere more deeply and earnestly cultivated. Your vast hospital in Dublin has now been open for nearly a century, but the returns of it show that the success of the last four Masters of it, (yourself included,) either as regards the saving of maternal or infantile life, has been less than that of the first four Masters who took charge of it in the last century. The last four Masters lost one mother in every seventy-five, and one child in every seventeen. The first four Masters lost one mother only in every seventy-seven, and one child only in every twenty.

I state these things with no intention to blame,—far from it; but I feel alarmed at the self-complacent way in which you seem to talk of the present supposed advanced state of midwifery. You accuse me of the "atrocious crime of youth." Every day I get older, and every day I feel more and more the vast amount of work that yet remains to be done by us all in midwifery, and I would fain excite you, if I could, to expend more of your abilities and talents upon the real advancement of that branch of medicine which you and I practise. Further, you seem to suppose that the seeing an enormous number of cases is the means by which this advancement is to be accomplished, and that my want of experience (as you choose to term it,) is enough to prevent me aiding in this good work. But I beg you again to remember, that it is not the mere mass of cases seen that has ameliorated, or that will ameliorate, the state of midwifery. In your hospital, upwards of 150,000 women have been delivered under the charge of different Masters. If we except, however, the names of Ould, and Clarke, I cannot, at this moment, recollect that any one of your other physicians, when acting as Masters, has added a single new fact to obstetric science, or propounded a single new principle in obstetric practice.

But I have said enough on this matter; let us pass on to other topics.

6. You say that, in my "Memoir on Turning," I have "ventured to condemn your practice." I am certainly not aware that I have done so. But you unscrupulously venture to condemn mine, and denounce the idea of turning in a case of contracted pelvic brim as "dangerous," &c., &c.; and you condemn it on grounds which shew at once that you misunderstood it. You suppose and argue that I wish to substitute turning in *all* cases of deformity of the pelvis, where the crotchet and long forceps are at present used. I never entertained or expressed such an idea. Thus, you erroneously imagine that I would have turned the children in all the seventy-nine cases in which you perforated their heads; and you add, "I shudder at the thought." I really do not see why we should "shudder at the thought" of saving *some* of their lives, instead of destroying them all. An old pupil of your own, your former able Assistant-Physician at the Dublin Hospital, and my esteemed friend, Professor Murphy, of London, met last December with a case (see *Lancet* for Dec. 18, 1847,) in which the pelvis was three inches in the congugate diameter of the brim, where the head remained above it, where he commenced *your* method of practice of perforating, but the instrument failed, and where he subsequently turned and delivered the child alive by *my* method of practice; and I have quoted in my memoir, several such instances. Would any man "shudder" at the thought of this child's life being saved by a new, when it was so nearly being sacrificed by an old, practice? Your countrymen have just been earnestly petitioning, and properly so, for one adult Irishman who has forfeited his life to the civil law. And why "shudder," then, at the thought of me petitioning with equal earnestness, for the lives of *some* of the next young Irishmen, that may, (if the old obstetric law is not changed,) be doomed betimes to have their heads opened, as formerly, by the perforator; and who, as yet, have committed neither crime nor treason of any kind. You are well aware that the Dublin returns present a much larger proportion of cases of craniotomy than those of any other hospital or school in the world. And one of our most able and most experienced practitioners in Scotland, (Dr. Wilson,) when, lately writing on the subject of the frequency of craniotomy, observed, not without truth—"It is to be feared that embryotomy is too lightly thought of; and our practice contrasts very strongly and unfavourably with that of criminal courts in cases involving life and death. With us the destruction of the life of a child is often determined upon, even without the formality of a regular consultation; whereas, with them, such is the importance attached to life, even when that life is loaded with imputed crime, that the greatest talent in the land are summoned to judge and bear witness in the cause, so that life be not sacrificed without the most undoubted proof of guilt." (See Dr. Wilson on the advantages of turning in certain cases of narrow pelvis.)

7. You believe that I wish to give up the long forceps, and substitute turning for them, and that I thus leap, (as you elegantly express it,) "out of the frying pan into the fire." Now, I do not any more imagine that turning should be a substitute for the long forceps in all cases, than that it should be a substitute for the crotchet in all cases. There are cases in which each is the appropriate plan of treatment. That I have not given up the long forceps, you will find by a paper of mine on the subject, published in the *Monthly Journal of Medical Science*, only two months back. In your letter to me, you object to the long forceps in the following terms:—"In most laborious labours the pelvis measures little more than three inches from the pubes to the sacrum; in others less than this. And when we consider the blades of the

smallest sized long forceps used in Britain, even when completely closed, measure from 3⅛ inches to 3½, it is clear that where the bones of the pelvis were denuded of their soft parts, there would not be space to admit of their application." Now, here, you commit two most extraordinary errors in relation to the mechanism and application of the long forceps. They are not applied antero-posteriorly,—that is, in the narrowest or most occupied diameter of the pelvis. The contracted pelvic brim is cordate or elleptico-cordate; and, (in this part of the world at least,) children's heads are not of that shape, but round or oval, and consequently, in entering the pelvic brim, they leave and must leave, laterally or diagonally, a free space on either side. It is in these free spaces that the blades of the long forceps are passed up by all who use them. Surely the rejection altogether of the benefits of the long forceps from the practice of the Dublin Hospital, when under your care, was based on grounds more valid than the two very strange and grave errors which you have here expressed on an important, yet simple, point in obstetric anatomy and obstetric surgery.

8. In relation to the operation of craniotomy, you try to show that the whole mortality from it was small. "Fifteen *only*," you say, "out of seventy-nine died;" that was one death in every five operations. Was that a *small* mortality? When the same operation was performed after labours of forty-eight hours' duration, my observations in regard to its mortality are, you state, "frightful indeed;" but, notwithstanding, you aver that the resulting mortality was "*marvellously* small," for you argue the deaths were only eleven out of the 6,414 deliveries," here reasoning again according to your old and erroneous mode of calculation, there were eleven maternal deaths out of twenty-seven craniotomy operations, or there died one in every two and a half delivered by the crotchet at that late period of the labour. Whether is this mortality "marvellously small" or "frightful indeed?" I willingly leave you and our readers to determine.

9. You give a statement of the supposed *cause* of death in the forty-two women who died after labours protracted beyond twenty hours. You do so evidently with the view of showing that they did not die of affections brought on by the protraction; but the whole list is a list merely of such injuries and diseases as tedious labour does produce,—viz., fever, inflammation, sloughing, rupture, &c. There is one striking exception in your table,—viz., one death entered from stricture of the intestines. Stricture, or chronic stricture of the intestines, was, you state, found on dissection, but how that stricture did or could possibly produce death without ileus, &c., you do not state. At last you ingeniously argue or what you term "demonstrate," that you lost only three patients instead of forty-two, from the effects of protracted labour. But I feel sure, that to the members of the Provincial Medical Association of England, it is utterly needless to expose such trifling with facts. Long ago surgeons always used to argue in regard to their lithotomy and other cases, that the deaths were from inflammation of the bladder or intestines, or disease of the kidneys or liver, or anything, in fact, except the operation itself. Modern surgery does not admit of such pathological casuistry; nor does modern midwifery.

If my time and space were not both alike exhausted, I would notice and correct other statements which you have made in your letter,—such as your declared idea that your "Practical Treatise" established a "*new era*," (is this expression not a misprint?)—your erroneous apprehension of the uses that I attribute to auscultation during labour; your allegation that "a child *cannot* pass alive" by turning in a deformed pelvis; your incorrect misrepresentation, (not, I trust, a wilful one,) of the results of anæsthetic midwifery in my own practice, and in the practice of the Maternity Hospital, &c. But I have said enough, I believe, to put on their guard your readers and mine as to the weight of your opinions and ideas on these and other matters. And apologizing for the very hasty, and consequently, very imperfect way in which these remarks have been thrown together, I beg you to believe me,

Very faithfully yours,
J. Y. SIMPSON.

Edinburgh, October 25, 1848.

[As both our esteemed correspondents have now stated their opinions at very considerable length, they will, we trust, excuse us for saying, that the dispute should end here.—Ed.]

Hospital Reports.

WEST NORFOLK AND LYNN HOSPITAL.

COMPLICATED SURGICAL INJURIES TREATED BY CHARLES COTTON, ESQ., M.D., F.R.C.S., &c.

COMPOUND FRACTURE OF LEG; TRAUMATIC DELIRIUM AND GANGRENE; SECONDARY HÆMORRHAGE: AMPUTATION OF THE THIGH: SUBSEQUENT MORTIFICATION OF THE STUMP: DEATH ON THE NINETEENTH DAY.

William Spinks, aged 50, agricultural labourer, admitted June 21st, 1848. He was conveyed by railway a distance of seventeen miles, and brought to the hospital late at night with a severe injury to the right leg, caused by the wheel of a cattle van accidentally passing over it. On examination, the integuments and flesh were found to be much lacerated and bruised, the bones fractured obliquely through the middle, slighty splintered, and protruding in front, and the periosteum of the tibia extensively denuded towards the knee. There was considerable bleeding of a dark colour, the pulsations of the arteries in the foot could, however, be distinctly felt. The poor man was greatly depressed in spirits, and anxious to have his leg spared if possible. His master, who followed him to the hospital, stated that his habits were steady and temperate, and that he was much respected. After some little deliberation, arising from the probable injury to the veins, and the mischief done to the soft parts, it was determined to attempt the saving of the limb. The leg was accordingly placed upon a soft pillow, guarded with oil-silk, the wound sponged, a few small particles of bone removed, and the fractured ends adjusted and retained in pretty good apposition, by means of foot-splints loosely applied on the outside of the pillow. Some inconsiderable riding of the bones was insurmountable, owing to the obliquity of the

fracture. The hæmorrhage became lessened, and afterwards ceased under the constant application of cold water.

22nd. The first part of the night painful and restless; a draught administered, containing thirty drops of Battley's sedative. Slept some hours from five this morning; is low and out of spirits, but free from pain. Rept. haust. hora somni.

23rd. A good night; limb easy. Slop diet.

24th and 25th. Progressing most favourably; the probable saving of the limb a source of much satisfaction to patient and surgeon.

26th. Much restlessness and wandering throughout the night.

Ten, a.m. Is now quite delirious, swearing and abusing different individuals for having caused his leg to be taken off. The pulse is weak, frequent, and wavy; he sighs frequently and deeply, and is continually tossing about the injured limb. Can be occasionally, for a moment, quieted, on being persuaded to look at his toes, and assured that an operation has not been required.

R. Liq. Opii Sedativi, m. xl.; Spt. Ammon. Arom., dr. j.; Mist. Camphoræ, oz. ij. Fiat haust. statim sumendus; and the following mixture every two or three hours, according to circumstances:—R. Ammon. Carb., scr. ij.; Spt. Æther. Sulph., dr. iij.; Liq. Opii Sedativi, dr. j.; Decoct. Cinchonæ, Julep. Camphoræ, part. æqual. ad oz. viij. Habt. oz. j., pro dosi.

27th. Wild and delirious throughout yesterday, and greater part of last night; gradually became more quiet under repeated doses of the mixture, and fell into a sound sleep, from which he awoke this morning rational and composed, ate some bread and milk, and has since taken porter at his own request. The pulse is weak, mouth clammy, tongue furred, eyes heavy, features sharpened, and cheeks tinged with a dusky hue. A few vesications observed on the leg above the seat of injury; the wound foul and offensive. Mistura repetatur ter die tantum.

28th. No return of delirium; injured parts gangrenous and sloughing; foot and ankle warm and unaffected. Apply yeast poultices. Chops and porter.

29th. Gangrene extending; much subcutaneous sloughing; eats sparingly, but enjoys his porter. Give nourishment without stint, in any agreeable form.

30th. Extension of mortification becoming limited to just below the knee.

July 1st. Appetite improved; feels better; gains strength; foot still warm, and comparatively but little involved. Amputation, in consultation, fixed for the 4th, conjointly with other operations, to give time for a more complete line of demarcation, and to establish further the strength.

2nd, 7 a.m. House surgeon called, a hæmorrhage (in quantity about 3lbs.,) having been detected, which had escaped the observation of the night nurse. Stimulants administered, and cold applied. This untoward event being reported, and an oozing of blood continuing, though in a trifling degree, the medical staff were summoned. The patient was found pale, prostrate, and almost pulseless, sighing frequently, and the skin cool. On being plied judiciously with porter, and somewhat rallied from its administration, amputation was sanctioned, as a last and most doubtful resort.

Operation.—The extremity requiring removal being gently raised from the bed, the artery commanded by the fingers in the groin, and the tourniquet as an additional safeguard applied loosely, *and tightened only on the very instant of operating.* The section of the thigh was commenced at its lower third (that point being deemed sufficiently beyond the diseased and sphacelated parts,) by transfixing the limb from its inner side, and forming an under flap by cutting outwards. The upper flap was next made by carrying the knife in a semilunar direction around the front of the thigh, from the termination to the point of commencement of the first incision, cutting from without towards the bone. The femoral artery was then at once secured with a ligature, the vein temporarily grasped with spring button forceps, the tourniquet removed, and *the bone afterwards sawn through,* and the operation speedily completed, with scarcely the loss of a drop of blood, thanks to the very able assistance rendered on the occasion. The poor fellow bore the operation without a murmur, and shortly after was almost imperceptibly lifted upon a bed placed along side ready to receive him. Ordered beef-tea, and wine or brandy in small quantities, should the circulation flag.

Two, p.m. Pulse quick, but less weak; skin hot, and profuse perspiring said to have followed the taking of some warm broth. Bed-clothes lightened. R. Acidi Sulph. Dilut., m. x.; Syrup. Aurantii, dr. j.; Liq. Opii Sedativ., m. v.; Decoct. Cinchonæ., oz. j. Fiat haustus statim sumend. dosisque repetatur omni tertia vel quarta hora.

Vespere.—Pulse 100; skin warm and moist. Had gradually rallied without the aid of stimulus.

3rd. Passed a tranquil night; pulse fuller, 90; extremities warm; stump easy. Let him have a light nutritious diet, and give the draught only at bed-time.

4th. Going on well; bowels unmoved. To have an enema of gruel and salt.

5th. A good night; bowels acted after the injection; stump easy. Full diet and porter.

6th. Another excellent night; enjoys his food and porter; is confident and happy, and appears stronger; bowels regular.

7th. The absence of reparative action in the stump remarked. To be diligently watched in case of hæmorrhage. Appetite failing; skin cool and clammy.

8th. Pulse languid; no union of stump-wound; edges of the flaps pale, flabby, and gaping, discharging thin curdy pus. Ordered wine.

10th. Countenance sunk and anxious; breathing hurried; pulse feeble; voice weak and tremulous; says he is not quite so well, and cannot eat; stump sloughing and gangrenous; the thigh above, particularly on the outer side, loaded, discoloured, and emphysematous; several phlyctænæ, containing a dark sanious fluid, extending to beyond the hip. Turpentine stupes to the stump; a free incision, affording no pain, along the outer side of the limb, liberated air, and much infiltrated cellular fluid. A draught of aromatic confection,

ammonia and æther, administered; to be repeated, if judged proper. Wandered at intervals, and declined gradually until the evening, when he was seized with a convulsive paroxysm, and died instantly.

Post-mortem examination.—Anæmic appearance of the body generally. *Heart* filled with black blood, the valves and lining membrane dyed of a deeply red colour, immovable by the sponge. *Kidneys* mottled, the vascular cortical structure pale; tubular substance, calyces and pelves, of a dark red colour, corresponding with the cavities of the heart. *Limb*:—Structures immediately about the stump disorganized and destroyed; thigh discoloured and distended with serum, to above the hip. *Femoral vein* enlarged; coats thickened; its extremity for about three inches or more occluded by cheesy coagulum and pus; the lining membrane as high up as the iliac trunk, of a dark red colour. *Femoral artery* at its termination impervious, and containing for a short distance a barrier of lymph, the side contiguous with the vein stained red; sheath of the vessels thickened.

Remarks.—The principal features of this case may be given in a few words. An auspicious commencement was unexpectedly cut short on the fifth day, by the accession of nervous or traumatic delirium, followed immediately by asthenic gangrene, the former subsiding under the adminstration of comforting anodynes, and the latter proceeding favourably to a stage of limitation, the system in the mean time becoming strengthened and improved, and a fit period for the operation considered to have arrived, when the disastrous and *negligently profuse* hæmorrhage took place, necessitating amputation under very trying circumstances. In spite of such discouraging complications the patient again rallied, and a further period of apparent well-doing gave the most sanguine hopes of a successful issue; the severity of injury, however, and its varied

Name.	*Age.*	*Admission.*	*Nature of Injury.*	*Under whose care.*	*Result.*
Henry Hudson	26	1847 March 20th	Compound comminuted fracture of the right leg; laceration and contusion of the left. *Five fragments of bone removed*	Mr. Cotton	Cured.
George Birch ..	17	March 20th	Compound comminuted fracture of the ankle; part of the inner side of the foot and heel carried away. *Subsequent gangrene.*	Ditto ..	Cured. Regained a partial but tolerably useful foot.
William Barber	37	March 27th	Compound comminuted fracture of the left thigh. Ends of the bones turned out of the wound and sawed off; four fragments removed.	Ditto ..	Died* May 24th.
George Rogers	19	May 19th	Compound comminuted fracture of the ankle; part of the internal maleolus and heel carried away. Contusion and injury to opposite ankle and foot.	Ditto ..	Cured. Regained a partial but useful foot.
Samuel Simpson	20	June 8th	Compound comminuted fracture of right leg; ends of bone sawed off to reduce fracture, by the House-Surgeon. Injury to the chest, and fractured ribs.	Ditto ..	Cured.
Wm. Humbleby	30	1848 Feb. 2nd	Compound fracture of the leg, and subsequent severe phlegmonoid and gangrenous inflammation. Extensive incisions required; bed sores, &c.	Ditto ..	Cured.
William Youngs	43	1847 May 13th	Compound comminuted fracture of left upper arm; contusion and laceration of right arm, and fracture of ribs.	Ditto ..	Cured.
Robert Gant ..	20	See *Provincial Journ.* No. 5, 1847	Compound comminuted fracture of right arm; lesion of brachial artery; frequently recurring erysipelas and diffusive inflammation.	Ditto ..	Cured.

* The notes of Barber's Case, report on the fifth day phlebitis of the limb; on the ninth and tenth, passive secondary hæmorrhage, yielding to cold applications; thirteenth, typhoid febrile disturbance and foul discharge; eighteenth, "progressing favourably;" thirty-eighth, "doing well," "union between the fractured ends;" forty-fourth, commencing colliquative diarrhœa and hectic exhaustion; fifty-eighth, death from sheer weakness. *Post-mortem.*—Liver lobulated; several foul sinuses around the femur; union between the bones broken down.

consequences, nervous shock, loss of blood, &c., had exhausted all powers of resistance, and the result proved *most vexatious*. General prostration and the want of reparative action in the stump, ended in recurring mortification of the limb, and death on the eighth day after amputation, and the nineteenth from the occurrence of the accident, the appearances observed at the *post-mortem* inspection leading to the opinion that the event was owing to *phlebitis and exhaustion*, rather than to the constitution being influenced by the mortification.

The usually considered fit period for amputation in ordinary cases of mortification, proceeding from the state of the system, was only waited for to give time for the renewal of nervous energy and strength, and not from any want of confidence in the practice established by Larrey, Guthrie, and other eminent surgeons, of amputating at the commencement or during the progress, *where injury has been the cause of mortification*, and the earlier the operation the greater the probability of success.

Complicated injuries of the extremities, such as compound comminuted fractures, with or without lesion of vessels, are productive of more anxiety than most other cases, and in the treatment require the most careful exercise of the judgment, to decide how far it be possible to save the limb, and therefore whether the attempt be justifiable.

The success attending *non-amputation* in several dreadful lacerations, arising from railway and other casualties, brought to the hospital during the last two years, led to the trial in the above narrated case. An outline of eight such mutilations is given in the table, in which the violence of injury and mischief was of an even more aggravated character than that sustained by Spinks, and the question of amputation surrounded by far greater difficulties, and in more than one instance was only settled by the patient intimating his determination not to submit to operation.

The difficulty of establishing accurate averages of results, is shewn by the circumstance of one dying out of the first four amputations of the thigh, and no other death occurring up to that of Spinks, the fourteenth similar amputation. Equally, and even more difficult, is it to furnish a correct statement (however important,) of *ultimate* results, owing to the almost impossibility of tracing out-patients after they leave the hospital.

Brooks, the third case of amputation of the thigh, discharged "cured" May 1st, 1844, re-entered the hospital February 14th, 1846, upwards of two years after the operation, "with vertebral abscess," "said to have been observed but six weeks." He left May 11th, and was reported as lately dead. "November 30th, 1846."

Although success may not in every instance be a fair test of the propriety of treatment adopted in individual cases, in the aggregate it is obviously the best criterion by which to judge of operative surgery; experience, therefore, and that on a large scale, and extended over a considerable period, can alone determine a question of such extent as the results of amputations.

[The West Norfolk and Lynn Hospital, through the liberality of the Governors, has recently been enlarged sufficiently to allow of the making-up of fifty beds, or more. The *reports* of operations and surgical cases treated by myself, and deemed *valuable* enough to merit a request for their continued publication in the *Provincial Medical and Surgical Journal*, will, I trust, in future embrace the results *of the whole* number of operations and cases, possessing any practical interest, falling to the charge of the surgeons of the Institution. C. C.]

October 16th, 1848.

In the *Provincial Journal*, December 23rd, 1846, a table was published of amputations, performed by Mr. Cotton, at the Lynn Hospital, from June, 1842, to August, 1846. (No accurate record of operations during the four previous years had been kept.) The following is an abstract of results:—

Amputations.			*Cured.*	*Died.*
Thigh.....	10 primary	1=11	10	1 of phthisis.
Leg.....	2 ditto	1= 3	2	1 of secondary hæmorrhage and gangrene. †
Shoulder-joint	ditto	1= 1	1	
Arm.....	ditto	2= 2	2	
Fore-arm....	ditto	3= 3	3	
Minor amputations and disarticulations of toes and fingers		= 8	8	
Total.....		28	26	2

To these have now to be added the following, occurring from August, 1846, to September, 1848:—

Amputations.			*Cured.*	*Died.*
Thigh	2 primary	1=3	2	1 Spinks' case above detailed.
Arm	2	=2	2	
Fore-arm	primary	3=3	3‡	
Minor amputations and disarticulations, excluding resections.		=8	8	
Total		16	15	1

			Total.	*Cured.*	*Died.*	*Mortality.*
No. of *capital* amputations	Immediate ..... 11 Secondary..... 1 For chronic disease 16	12	= 28	25	3	1 in 9⅓
No. of extreme cases during the last 18 months *treated without amputation*			= 8	7	1	1 in 8

† See Taylor's case, No. 51, *Provincial Journal*, 1846.

‡ *Provincial Journal*, No. 19, 1848. *Bulman* recovered from the amputation of the fore-arm, but died ultimately from the gun-shot injuries to the skull and brain.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF PROFESSOR SANDS COX, F.R.S., SENIOR SURGEON TO THE HOSPITAL.

Reported by PETER HINCKES BIRD, Resident Medical Officer.

CASE XI.

DISLOCATION OF THE RADIUS AND ULNA BACKWARDS.

Thomas Gavin, aged 20, hawker, admitted December 25th, 1847, under the care of Professor Cox. He states that he slipped down about half an hour ago, and fell with his left arm bent under him. On getting up he found that the use of his fore-arm was gone, and that he could not bend his elbow.

On examination, it was found that there was dislocation of both the radius and ulna backwards, on the left side; the shape of the elbow-joint was much altered, and there was a considerable projection posteriorly, formed by the olecranon process, on each side of which a distinct hollow could be felt. The lower extremity of the humerus could be felt as a hard swelling, immediately behind the tendon of the biceps muscle; the hand and fore-arm were placed in the supine position; pronation could not be entirely effected, and flexion of the joint was much impaired. The head of the radius could be felt behind and above the external condyle; there was no fracture of the coronoid process. The distance between the bend of the elbow and the wrist appeared to be shortened. He was intoxicated at the time, and did not complain of much pain.

Reduction was effected by placing the knee in the bend of the elbow, and extending the fore-arm in a direct line, and whilst the pressure was kept up by the knee, the arm was slowly but forcibly bent. Cconsiderable extension was required, as the patient was a muscular man. The fore-arm was then placed in the bent position, forming rather less than a right angle with the upper arm, and warm fomentations applied.

26th. Feels comfortable; there is some slight swelling about the elbow-joint; complains of slight numbness in the little and ring fingers; can move the elbow-joint freely.

28th. Discharged cured.

This accident usually takes place in a fall when a person instinctively puts out his hand to save himself. In this case it generally happens that the superior extremity, instead of resting vertically upon the ground, is placed obliquely with the hand nearly in a state of supination. The repulsion which it receives from the ground will cause the two bones of the fore-arm to ascend behind the humerus, whilst the weight of the body pressing on the humerus, directed obliquely downwards, forces its extremity to pass down anterior to the coronoid process of the ulna.

The swelling which supervenes after the accident may obscure the diagnosis; but notwithstanding the assertion of Boyer, the olecranon and internal condyle are never so concealed that the distance between them cannot be felt to be increased. Sometimes the friction of the coronoid process against the humerus may cause a grating noise, similar to that of a fracture, and some attention is requisite to establish the diagnosis between a fracture of the head of the radius, and a dislocation of the fore-arm backwards.

A dislocation of both these bones backwards must be attended with serious injury to the surrounding soft parts. The lateral ligaments, and the orbicular ligament of the radius, are frequently found ruptured. In a case dissected by Sir Astley Cooper, the coronary ligament was found entire; the biceps muscle was slightly put upon the stretch by the radius receding; but the brachialis anticus was excessively stretched by the altered position of the coronoid process of the ulna.*

The lower insertions of the biceps and brachialis anticus are sometimes found ruptured by the violent protrusion of the lower extremity of the humerus forwards; and cases are recorded by Petit and Mr. Samuel Cooper, in which the lower end of the humerus, indeed, not only lacerated these muscles, but burst through the integuments, and presented itself externally.

CASE XII.

FRACTURE OF THE BODY OF THE SCAPULA.

William Pemberton, aged 34, smith, admitted as out-patient, April 20th, 1847, under the care of Professor Cox. He states that yesterday afternoon, he fell down and struck his left shoulder very forcibly against a stone step; when he got up he found that he could not raise his arm.

On admittance, it was found that he could not raise his arm from his side; he complained of much pain through the shoulder; crepitus was most distinctly heard and felt on applying the flat hand over the scapular region, and on raising the arm, it appeared that the fracture extended through the body and spine of the left scapula, in an oblique direction, separating the inner from the outer two-thirds. The parts about the shoulder were much bruised. A pad was placed on the scapula, and retained in its position by a figure-of-eight bandage, and the arm fixed to the side.

23rd. Feels much easier; the pain is less felt; there is considerable ecchymosis of the shoulder. The bandage, being loose, was re-applied.

May 4th. Doing well; the bones are in good apposition.

21st. Quite well; can raise his arm, but cannot yet use his shoulder-joint freely.

Fractures of the body of the scapula are rare; this portion of the bone is more deeply placed, and is protected by thick muscles; it also moves upon a large muscle, which serves as a cushion to it, and deadens a blow when applied to it from behind. Fractures of this bone can only be produced by direct violence, and in this case it seems that it was caused by a sudden fall on the shoulder, the scapula striking forcibly against a stone step.

Fractures of the body of the bone are mostly accompanied by much contusion of the soft parts, and sometimes by injury of the thoracic viscera. Sometimes, as in the above case, they are vertical, but most commonly are transverse. In vertical fractures it is merely necessary to fix the arm to the side, by means of a bandage, which includes the arm and trunk, from the shoulder to the elbow, thus preventing the motions of the shoulder, which are only concomitant with those of the arm. When the fracture is not complicated with other injuries, the union generally takes place in about four or five weeks, not requiring a longer time than the fracture of

* On Dislocations and Fractures of the Joints, p. 441.

other bones. The free use of the shoulder-joint, however, is not recovered until some time after, owing to the bruising of the muscles, and the thickening of the parts round the bone. The confined position of the limb also opposes their early use, and deprives them of their action.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, NOVEMBER 1, 1848.

In our last number we made some extracts from the directions issued from the Central, or Dublin, Board of Health, relative to the management of Cholera cases, and more especially to the precautions to be observed in all cases of diarrhœa wherever the cholera has appeared or threatens to appear. These precautionary measures in diarrhœa, which has been found so frequently to be the preliminary stage of cholera, we believe to be the most valuable part of the directions hitherto issued by various authorities, and a due attention to them on the part, both of the profession in the treatment, and of the public as a warning to have immediate recourse to professional assistance, to be the most effective means in limiting the destructive ravages of the pestilence. It had been our intention in the present number to give an analysis of the directions issued by the General, or London, Board of Health; but constituted as that body is, we cannot but feel that it neither possesses the confidence of the profession, nor did it, at the period when these directions were first issued, possess any of the qualifications necessary to deserve that confidence; we prefer, therefore, on the present occasion, rather to look to the northern metropolis. We are glad to observe that the members of the Local Board of Health established in Edinburgh, have submitted their code of instructions to the consideration of the Royal College of Physicians of Edinburgh, by whom at a meeting held on the 12th instant, they have been unanimously and cordially approved. These instructions come, therefore, with the sanction of the highest medical authority in that part of the United Kingdom, and are entitled, we think, to the confidence of the profession generally. They are as follows:—

I. To avoid excess in the use of spirits; experience having shown that it is not uncommon for a fit of intoxication to pass into an attack of cholera.

II. To observe more than ordinary care in avoiding cold from light clothing or wet; and when the body has been accidentally chilled, to restore warmth by artificial means, especially by the warm foot-bath.

III. To use as substantial a kind of food as possible; avoiding free indulgence in liquids of all kinds, and the use of uncooked vegetables, unripe, sour, or stone fruit, the poor kinds of small beer, all tart sorts of malt liquor, ginger beer, and acid drinks generally.

IV. To shun long fasts; above all when business obliges any one to be much in places where cholera prevails.

V. To attend to the proper regulation of the bowels; and therefore—

1. To check a tendency to looseness of the bowels. It has been everywhere found that many cases of cholera are preceded for a short time by a warning stage of looseness of the bowels, in which stage the disease may be arrested, although it is with difficulty cured when farther advanced. When any one, therefore, is attacked with looseness, although unattended with pain or other inconvenience, he should, if possible, apply for immediate medical advice. And if advice cannot be obtained at once, he ought in the meantime to take a pill composed of one grain of opium, or fifteen drops of morphia-solution or laudanum in a little water; and he should repeat the dose in an hour, if not relieved. He should also take a teaspoonful of compound tincture of cardamoms undiluted, or compound tincture of cinnamon, or tincture of ginger, diluted with a tablespoonful of water, or, in the want of these, a little warm brandy and water, and avoid at the same time all cold drinks, or much drink of any kind,

N.B. Half the above doses for young persons about fourteen, and one-fourth for children about five. Opium, laudanum, and morphia, not to be given to very young children without medical advice.

2. To correct a liability to costiveness. For this purpose, saline purgatives, such as Epsom salt, Glauber's salt, and effervescing powders, and strong purgatives of all kinds, or large doses of any purgatives, should not be used during the prevalence of cholera unless under medical advice,—but only such mild laxatives as castor oil, Gregory's mixture, the lenitive electuary, compound rhubarb pills, colocynth and henbane pills, or any other medicine known by experience to act mildly. And any undue effects accidentally produced by such medicines should be counteracted by opium, laudanum, or morphia, as above.

VI. To attend also promptly to attacks of sickness or vomiting, which sometimes precede the epidemic, and which, after the stomach has been once cleared out, may be treated by the same remedies as those directed for looseness of the bowels.

At the same meeting, the following resolutions were adopted unanimously:—

1. That it is not advisable to remove cholera patients from their own houses if it be possible to command advantageously the means of treating them there; but that, according to experience in the former epidemic, a large proportion of cases must occur in Edinburgh among the lowest population, inhabiting apartments in which it is impossible to treat the sick for want of proper beds, bedding, fires, and other means of heating the body, besides other necessary medical resources.

2. That, on the occasion of the former epidemic, serious injury was in many cases caused in this city by the direction of one of the Boards of Health in London, to

avoid the use of laxatives during the prevalence of the epidemic, and rather to encourage a somewhat constipated condition of the bowels, inasmuch as many accustomed to use laxatives, and requiring their occasional or regular use, gave them up, and suffered from the consequences of constipation, the College seeing no reason why mild laxatives should not be used for the removal of constipation during cholera, and believing that both cholera and other serious intestinal diseases may arise from a neglect of them in many circumstances, unanimously approve of the regulation V. 2, as stated above.

The first of these resolutions is called for in consequence of the condemnation of hospitals, contained in the directions of the London Board of Health, being inapplicable in Edinburgh, where the population chiefly liable to cholera is, in general, absolutely destitute of all the appliances necessary to render medical treatment available. The second has been called for in consequence of many persons here having fallen into the very same error which is stated to have occurred in 1832, although the directions of the London Board of Health are by no means so condemnatory of the use of all laxatives as on that occasion.

The College of Physicians also passed a unanimous resolution strongly approving of the establishment, as in 1832, of Houses of Refuge for the removal of the healthy from localities threatened with a severe visitation of the epidemic. This measure was carried through energetically by the Edinburgh Board of Health during the first epidemic; so that at one period upwards of 700 persons from infected districts were lodged under observation in Houses of Refuge, but allowed to go to their usual places of work. There is no doubt, according to the opinion of the best judges, that the ravages of the disease were in that way greatly circumscribed in various localities in Edinburgh; and that no other measure contributed so much to keep the epidemic within moderate bounds. The utility of such Houses of Refuge must be obvious to all, whether the disease be viewed as originating in infection, or, as seems now far more probable, in a peculiar miasm prevailing with intensity only in limited localities.—*Edinburgh Advertiser* in *London Medical Gazette*.

We cannot conclude without directing special attention to the opinions expressed with reference to the formation of hospitals and houses of refuge. The Edinburgh College evidently considers that the rule condemnatory of cholera hospitals, attempted to be laid down by the London Board, is not applicable to the population of the northern metropolis, while they are strenuous in recommending, what we believe was found most effective in checking the spread of the disease wherever it was properly carried out,—the removal of the healthy from infected houses and localities. We have not now space to pursue the subject further, but had the General Board of Health been constituted, as it ought to be, of medical men of eminence and experienee, or had condescended before issuing their directions to communicate with the secretaries of the several Local Boards of Health which were formed throughout the country during the former epidemic, a mass of information on this and other points might have been obtained, which would have enabled them to produce a document of a very different description to that issued under the signature of Henry Austen, by the amiable noblemen and ingenious legal gentleman of whom the present Board consists.

Proceedings of Societies.

BATH AND BRISTOL BRANCH ASSOCIATION.

The Quarterly Meeting of the Bath and Bristol Branch was held at Bristol, on September 28th, 1848, F. Flower, Esq., in the chair.

There were present Drs. W. Budd, Green, and Trotman ,Messrs. Colthurst, Estlin, Godfrey, Mayor, Mortimer, Neild, Ogilvie, and Swayne, of Bristol; Race Godfrey, of Yatton; Dr. Blackmore, Messrs. Bartrum, J. Barrett, George, King, Hunt, Lloyd, and Norman, of Bath; &c.

PHLEBITIS: GASTRO-DUODENITIS.

Mr. George read a case of sudden death, connected with pregnancy of four months, phlebitis of the crural and uterine veins, and duodenitis. (To be published in the Journal.)

Mr. Hunt mentioned a case of a similar character, where, in addition, on examination, the brain was found softened; and there was a large effusion of fluid within the arachnoid.

Dr. Blackmore observed, that in certain constitutions of a scrofulous character, inflammatory appearances and symptoms *will unexpectedly present themselves in the upper intestines*. The time of such morbid development is quite uncertain, especially in elderly people, where after sudden death the upper intestines are not unfrequently found diseased, when such a morbid condition was not suspected during life, organic changes arising in them very rapidly. In all cases the occurrence of phlebitis added much to the tendency to death by syncope. He had known cases of suppuration completed in five hours, bearing a close analogy to cases fatal by the perforation of some part of the alimentary canal. In proof of the rapidity with which inflammation of the bowels may arise, he mentioned a case of a child, scalded on the neck and chest, in whom, after living for ten hours, the upper intestines were found most markedly inflamed.

Mr. Lloyd had known cases of perforation of the bowel fatal in less than two hours.

Mr. Norman observed, that in the case just read, the pus in the uterine veins was the most important point. All observers recognized the tendency to the rapid development of local inflammation in cases where the blood was poisoned by phlebitis of even small extent. In this case inflammatory action had suddenly been set up in the gastric and duodenal regions, causing the intense pain and death, by impression on the heart.

Dr. Green observed, that in cases of phlebitis, pus may be laid down very suddenly, and the local deposits of pus are occasionally carried off, and excreted by, the mucous membranes. Van Swieten mentioned the apparent evacuation of abscesses by the urine. Dr. Green instanced, as a proof of the rapidity of death in phlebitic cases, a man who, having suffered from phlebitis, with very rapid pulse, and general excitement, died very suddenly without any premonitory symptoms. On examination, the internal iliac vein was found filled with pus to its junction with the common iliac. On the closest examination no deposit of pus could be found in any part of the body, nor were any purulent corpuscles found in the heart or the blood, death having occurred by an intense impression on the heart.

POISONING BY YEW BERRIES.

Mr. Lloyd then read a case of poisoning by yew-berries. (To be published in the Journal.)

Dr. Trotman, as a schoolboy with his comrades, had often eaten freely of the drupes of the yew, and never experienced any ill effects, if the mucous covering alone was swallowed, the poisonous principle being in the central berry.

CROUP.

Mr. Norman then read an account of a case of croup in the adult, fatal in less than twenty-four hours, (to be published in the Journal,) illustrated by two coloured wax models. He narrated several cases of similar kind that he had seen at various times.

Dr. Blackmore, five years ago, had suffered from the same complaint, and strongly urged on the meeting the importance of treating such cases by continued doses of oxymuriate of mercury.

Dr. W. Budd drew attention to cases of similar disease, closely analagous to erysipelas, presenting after death but slight plastic exudation, though the membrane was deeply injected and swollen. That these cases were erysipelatous in character was shewn by erysipelas supervening on the operation for tracheotomy, or by its spreading upwards to the outer surface of the face, as well as by erysipelas being very prevalent at the same time. Dr. G. Budd had read an account of several such cases before the Medico-Chirurgical Society, when Mr. Busk, of the *Dreadnought* recommended the free scarification of the velum palati and tonsils, thereby giving exit to an immense flow of blood and serous fluid, with immediate relief to the patient.

Dr. Green observed, that though some of these cases might be connected with erysipelas, yet the point of most practical importance was, not to defer the operation of tracheotomy too long. When once œdema came on, mercury was the only trustworthy remedy, antimony being most useful in the early stages. In the cases he referred to, the difficulty was in inspiration, which was characterized by short strenuous inspirations, accompanied by great anxiety to expire the vitiated air.

Mr. Hunt briefly related a case of the same character, where, after copious bleedings from the arm, leeches to the larynx, and five grain doses of calomel every two hours, it was intended to have performed tracheotomy. On the calomel producing its specific effects, the urgent symptoms immediately subsided, and the patient recovered.

TOLERANCE OF OPIUM.

Mr. Godfrey, (of Bristol,) narrated two cases at present under his care, illustrative of the large doses of opium that can be borne without narcotism. In one the lady swallowed frequently forty grains of opium within the day; in the other, the patient who for years had been subject to violent neurotic attacks, often took within the day sixty grains of the acetate of morphia.

Mr. Norman some years ago had a gentleman who suffered from senile gangrene, from which he recovered; he then took opium, and subsequently took a wine-glassful of laudanum regularly twice a-day. He obtained from Apothecaries' Hall twenty drachms of opium, which after cutting up he macerated for above a month in a quart of brandy; of this tincture he took two glasses a-day, without any further sensible effect than to exhilarate his spirits. While taking this, on two occasions constipation came on, with imminent risk to his life. After the second attack, he at once left off all his opium, and lived four or five years afterwards, dying eventually of disease of the brain.

Dr. Blackmore had known four hundred grains taken in one day, without narcotism being produced.

THE CHOLERA.

A conversation illustrative of several points in the history of the Asiatic Cholera ensued, in the course of which Mr. Norman mentioned the following facts:—

In 1832, the cholera broke out in two houses in Avon Street, Bath, almost all the inmates of which houses died. From there it spread to the immediate vicinity, to which it was confined with very few exceptions. These houses were then shut up and purified, a house in the same street was taken as an hospital, and the proportion of recoveries was greater, but neither the nurses nor other attendants, though in the closest and most continuous intercourse, caught the disease.

The next year an isolated case occurred in Avon Street, and within a few days another in Mill Street, (parallel with, and on the same low level as the former street.) A man was sent from the Poor-house to superintend their immediate interment, and he followed them to the grave. Within a week, the town being otherwise quite free of the disease, it broke out suddenly in the Idiot Ward of the Poor-house, situate at a considerable distance from the former cases. Of these idiots, 12 out of 15 died. There had been no communication with them from the town, nor did the disease exist in the other parts of the Poor-house. The only apparent source of the disease was by this man, who was their usual attendant, and had been sent to direct the burial of the two cases occurring in the town. In the next year, 1834, isolated cases again presented themselves at different points.

Mr. Swayne mentioned that at Coalpit Heath, two years after the cholera had left the locality, some cases occurred among the miners working in a particular shaft; they were removed to their homes above, where the disease did not spread. It was then observed that those working in the night-gangs were only attacked;

they were accordingly brought up, the night-work stopped, and the disease did not spread further.

Other cases were referred to by Mr. Ogilvie, and other members, illustrative of the little tendency it had to spread in the cottages of the rural districts, or where ventilation was moderately attended to.

DORSET COUNTY MEDICAL ASSOCIATION.

The Autumnal Meeting of the Dorset County Medical Association was held at Dorchester, on Thursday last, Mr. Nott, of Bere Regis, in the Chair. Among the Members present were—Mr. Salter, Mr. Curme, Mr. Arden, Mr. Empson, Mr. R. Shettle, Mr. Druitt, Mr. Davis, Mr. Cole, Mr. T. Nott, Mr. Spooner, the Secretary of the Association, Dr. Williams, Mr. Fookes, and Mr. Fox.

The Secretary then read the minutes of the last meeting, after which Mr. Druitt, of Wimborne, read a paper on the history, advantages, and disadvantages of chloroform, and other anæsthetic agents in operative surgery and midwifery. This paper, which is an elaborate resumé of the facts and reasonings hitherto published on the subject, and contains much original matter of considerable interest, produced an animated discussion.

Mr. Salter, of Poole, read a paper on scrofulous or strumous disease, illustrated by numerous pathological preparations and original cases.

The question of Medical Reform was then discussed at considerable length, and a resolution was unanimously adopted in favour of the draft of the bill which the United Conference at the College of Physicians in London had agreed upon, copies of which were placed on the table by the Secretary. The report of the National Institute of Medicine and Surgery was considered highly satisfactory, and deserving of the full confidence of the general practitioner.

The correspondence of the Secretary of the Dorset County Friendly Society was then read and commented on, and the satisfaction of the meeting was expressed respecting the new medical arrangements which are proposed for adoption.

The new Sanitary measures lately enacted were afterwards considered, and a resolution adopted expressive of the cordial concurrence of this Association.

The Honorary Secretary, (Mr. Spooner, of Blandford,) then read his report for the half-year, which contained amongst other subjects, a report on the Asiatic Cholera.

It was arranged that the next meeting of the Association should be held at Poole.

[The papers read at the Meeting will be published in future numbers of ihe Journal.]

General Retrospect.

DOUBLE GALACTOCELE.

Under this title, M. Vedal *(de Cassis,)* relates the case of a soldier who returned to France with a double hydrocele, for which he was tapped. Instead, however, of the fluid being of the ordinary character, it had all the appearance of milk. It was opaque, white, of the consistence of milk, without smell, of a taste slightly saltish but not disagreeable. It did not coagulate by heat. Analysis shewed that it was composed of water, with a matter very like casein, a fatty matter resembling butter, sugar, chloride of sodium, lime; but it did not contain any of the phosphates. The tunicæ vaginales were injected with solution of iodine, and a cure was effected as in ordinary cases.—*Archiv. Gen.*, Sept. 1848.

CHOLERA TREATED BY CHLOROFORM.

Mr. Brady reports the following case:—Mary Parratt, aged 60, ordinarily enjoying good health, was on Saturday, September 29th, attacked with slight diarrhœa, for which the usual homely remedies were used. On the following morning at 6 o'clock a.m. the diarrhœa became profuse; excessive vomiting supervened, accompanied by spasms in the calves of the legs, fingers, and toes. Notwithstanding the urgent nature of the symptoms, reliance was still placed on the favourite remedy, brandy, without avail, however; the dejections became incessant, the spasms increased in intensity, and at 9 o'clock a.m., on Sunday, the 30th, Mr. Brady was called in to see the patient, who, it was affirmed, was in a "dying state." Believing, from the description given, that he should have to treat genuine malignant cholera, and having predetermined, should such a case present, to try the effects of chloroform administered internally, he took with him the following mixture:—R. Chloroform., dr. j.; Ol. Terebinth., oz. j.; Aq. Dest., dr. iij. M.

On his arrival he found the patient presenting all the symptoms of malignant Asiatic cholera in an advanced stage: the features collapsed and ghastly; extremities and tongue cold; burning sensation in the stomach and œsophagus; pulse rapid and scarcely perceptible; voice diminished to a whisper; stomach exceedingly irritable, and the dejections from the bowels presenting the characteristic rice-water appearance; and all the voluntary muscles of the body were affected by spasm, so that the patient actually writhed in agony. He immediately administered a large teaspoonful of the chloroform mixture (containing about twenty minims of chloroform and forty of turpentine) in a wine-glass of dilute brandy, and applied synapisms to the calves of the legs and abdominal and thoracic surface. Thirst was relieved by drinking plentifully of water, nearly cold. Notwithstanding the irritable state of the stomach, he had the satisfaction to find that the chloroform draught was retained, as well as the fluid drunk after it, and was followed by no dejection. He now (half an hour after the draught,) gave two of the following pills:—R. Calomelanos, scr. ss.; Fellis Bov. Inspis., scr. j. M. et divide in pilulas quatuor.

In an hour after the administration of the chloroform, vomiting ensued of a portion of the fluid drunk, slightly tinged with the gall; this soon subsided, the diarrhœa had apparently ceased, and the cramp diminished in frequency and severity. He now administered a second dose of the chloroform mixture, and soon after repeated the pills. The stomach retained both; she soon felt decided relief; the pulse rose in power and became slower, the spasms less frequent, and in an hour after the second dose she was bathed from

head to foot in a warm perspiration, and expressed herself comparatively free from all uneasy sensations. The attack had been completely subdued, leaving behind a good deal of pyrexia and debility, from which she is now rapidly recovering.—*Medical Times*, August 12th.

CHLOROFORM IN CHOLERA.

Mr. Stedman relates the following case:—Mrs. Smith, aged 55, of bilious temperament, prone to diarrhœa, was on Monday evening last seized with all the symptoms of an attack of English cholera—vomiting, purging, excessive spasm of the body and extremities, small rapid pulse, and insatiable thirst. The dejections were of a frothy character, resembling yeast, and the matter ejected from the stomach of the same nature. Recourse was had to the usual remedies prescribed in this disease, with strong terebinthinate stupes to the abdomen and calves of the legs, and injunctions given as to diet, &c. Having attended her before for the like symptoms, I prognosticated a favourable and speedy result. About three o'clock on the following morning I was hastily aroused by her husband, as the patient had become much worse. All her symptoms had increased to an alarming degree; the spasm was universal and excessively violent, "as if knots were being tied in her bowels;" vomiting incessant; countenance livid and cold; articulation feeble, praying to be released from her sufferings. As all the medicines had been rejected, I thought it fruitless to continue them, but at once decided upon administering chloroform; the following mixture was prescribed:—R. Chloroform., gtt. xiv.; Aquæ Vitæ,(Cogn.,) oz. j.; Aquæ Destill., ad oz. vj. M.

A fourth part was given immediately, which had a partial but most satisfactory effect; an abatement of all her symptoms was the immediate consequence. In two hours a disposition to a recurrence manifested itself, when a second dose of the mixture was administered, which entirely controlled all spasms, vomiting, and purging. She expressed herself "very comfortable." and fell into a quiet sleep. At nine o'clock I again saw her, and found her suffering only from febrile symptoms, accompanied with much exhaustion. She was ordered cold rice and mucilaginous drinks, and had the chalk mixture with nitric æther prescribed. A dose of ox-gall (gr. x.,) was given in the course of the day, which produced three bilious evacuations and some disposition to vomiting, which soon passed away. In two days she was declared convalescent. In 1832, when the cholera visited this place, my patient was attacked, but she declares her sufferings then were nothing in comparison with her late disorder. The two remaining doses of the chloroform mixture were ordered to be carefully preserved in case she had any return of her symptoms. A daughter, grown up, who had assiduously attended upon her mother, was on Wednesday evening, seized in precisely a like manner, except that the dejections were more abundant and frequent; and the mother, without hesitation or appeal for advice, gave her the two remaining doses of the mixture. The same result followed; the first dose was only partial in its effect, but the second completely subdued the disease. When I called on Thursday, the gratifying announcement was made to me of the success of my medicine in a second case.—*Medical Times*, August 23rd.

REPORT OF THE NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,—In the last number of the Journal you directed the attention of your readers to the Report of the Council of the National Institute of Medicine, Surgery, and Midwifery, on the present state of the Medical Reform question. It has been forwarded to me, and I have read it, and as you anticipated, with much interest; and when we consider the great importance of the subject they had to deal with, and contemplate the effect which the changes and the reforms recommended will have on the various classes in our profession,—the immense interests of the numerous corporate and governing bodies they had to contend with,—and also the many attempts and abortive measures of the Legislature and the Government, I do think their Bill and Charter is a move towards perfection, and likely to reconcile the discordant views of the different parties concerned, and to meet the difficulties and remove the anomalies so long complained of by a large number of the members of the profession. So far as they have gone, the Council of the Institute and the delegates from the other medical and corporate bodies are justly entitled to the thanks of the whole of the medical and surgical profession, for the progress they have made in the cause of Medical Reform. But while I approve of what they have done, I must also tell them of what they have left undone. I observe with deep regret, that the practice of midwifery is not mentioned in either the Bill or the Charter; this is a most unpardonable omission, and to me unaccountable. If the word midwifery be added to clause 7, in the "Bill for regulating the Practice of Physic and Surgery," I will also join in heartily thanking them for all they have done. From what we almost daily read and hear of the mal-practice in this branch of the profession, it is awful to think that the lives of the women and wives of this country and their infants should be left unprotected by the Legislature, and in the most trying and difficult circumstances, to the treatment and tender mercy of the ignorant and unskilful. This is to me unaccountable; and it is strange that an united body of professional men, who were associated together for the express purpose of securing to the public legal protection from incompetent and unqualified practitioners, as well as to protect themselves from the uneducated and unlicensed, should, in the draft of their Bill, have entirely excluded the practice of midwifery. Surely it could not be wilful. This branch of the profession does more to raise a man into practice, and endear him to, and secure him patients, than any other part of the practice of medicine and surgery, and they ought to know, and not to be told the consequence of this omission. I trust Sir, you will not only publish this letter, but that you will also draw the

attention of your readers to this defect in the measures of reform recommended by the Council of the National Institute, and urge them to get it remedied by adding the practice of midwifery to the Bill, thereby securing to her Majesty's female subjects protection from dangerous and incompetent practitioners in midwifery, and you will oblige.

Your obedient servant,

Bath, Oct. 25, 1848. GEORGE KING.

Medical Intelligence.

THE CHOLERA.

RECOMMENDATIONS OF THE BOARD OF HEALTH.

At a Meeting of the medical practitioners of Worcester, held October 19th, 1848, at which twenty-one members of the profession were present, Dr. Hastings in the chair, it was moved and seconded:—

1. That it appears to this meeting, that on the late occasion of the prevalence of cholera in Worcester, it was found very beneficial to have a separate establishment in a healthy locality, for the treatment of cholera patients, and also an establishment for receiving the inmates of houses in which the disease had occurred, and who had not been affected. This meeting cannot therefore concur in the recommendation of the Board of Health, that cholera patients should be received into the General Infirmary or at the Dispensary.—The resolution was carried with two dissentients.

2. That Dr. Streeten be requested to publish the foregoing resolution in the next number of the *Provincial Journal*.—Carried unanimously.

APPOINTMENTS.

Thomas Macaulay, Esq., has been elected one of the Surgeons to the Leicester Infirmary.

John Simon, Esq., F.R.C.S., has been elected Health-officer to the City of London.

MANCHESTER MEDICAL SOCIETY.

The following gentlemen have been elected office-bearers for the ensuing session:—*President*: Dr. Radford. *Vice-Presidents*: Mr. Hunt, Mr. Noble, Dr. C. W. Bell, Mr. Wilson. *Treasurer*: Dr. Ashton. *Hon. Secretaries*: Dr. Renaud, Dr. H. Ried. *Librarian*: Mr. Stone. *Councillors*: Messrs Brownbill, L. B. Harrison, Dumville, Lomas, Southam, Catlow, Spence, Allen, Bowman, Golland, Dr. Wilkinson, Mr. Franklin.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, Oct. 19th:—Robert William Ellis, Bristol; Robert Webster Gillespie, Newcastle-on-Tyne; John Mc'Millan, Hull.

OBITUARY.

Died, September 28th, at Weston-super-Mare, aged 84, Titus Owen, Esq., M.R.C.S., of Cheltenham.

September 30th, at Cumnock, in the County of Ayr, aged 52, Douglas Wills, Esq., Surgeon, from the absorption of poisonous matter in removing a gangrenous limb.

October 10th, from prussic acid, taken it is supposed in an over-dose, Frederick Nesbitt, M.D., M.R.C.S., Yeovil, Somerset.

October 18th, Thomas Blanchard, Esq., Surgeon, Pimlico.

BOOKS RECEIVED.

On Medical Education, an Introductory Lecture, delivered at the Liverpool Infirmary School of Medicine, at the opening of the Medical Session, 1847-8. By Joseph Dickinson, M.A., M.D., F.L.S., &c., Physician to the Liverpool Infirmary, and Lecturer on the Theory and Practice of Medicine. London: Churchill. Liverpool: Deighton and Laughton. 1848.

Microscopic Anatomy of the Human Body in Health and Disease. By Arthur Hill Hassall, F.L.S., &c. Part XIV. London: Highley. 1848.

Hints towards the Formation of a more Comprehensive Theory of Life. By S. T. Coleridge. Edited by Seth B. Watson, M.D., &c. London: Churchill. 1848. pp. 94.

On the Ganglionic System of Nerves. By C. Radcliffe Hall, M.D., M.R.C.S., &c. Part III. 8vo. pp. 77.

Clinical Lectures on the Practice of Medicine. By Robert J. Graves, M.D., M.R.I.A., &c., &c. Second Edition. Edited by J. Moore Neligan, M.D., M.R.I.A., Physician to Jervis Street Hospital, and Lecturer on the Practice of Medicine in the Dublin School of Medicine, &c. Dublin: Fannin and Co. London: Longman and Co. 1848. 8vo. Vols. 2. pp. 586, 570.

On the Influenza, or Epidemic Catarrhal Fever of 1847-8. By Thomas Bevill Peacock, M.D., Licentiate of the Royal College of Physicians, Physician to the Royal Free Hospital, and to the City of London Hospital for Diseases of the Chest. London: Churchill. 1848. 8vo. pp. 184.

On Femoral Rupture; its Anatomy, Pathology, and Surgery. By John Gay, F.R.C.S,E., Surgeon to the Royal Free Hospital, &c. &c. London: Highley. 1848. 4to. pp. 97. Plates.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

EXTRACTS FROM A REPORT

ON THE SANITARY COMMISSION, THE BOARD OF HEALTH, AND THE ASIATIC CHOLERA.

By EDWARD OKE SPOONER, Esq., Blandford.

[Read before the Dorchester Medical Society, Oct 12, 1848.]

At this time of the world's history, when steam-vessels and railways have rendered the communication between all parts of the world so rapid and so multiplied, it becomes us all to take sound views respecting the communicable character of various important diseases. The cupidity of merchants aims at nothing less than the annihilation of all quarantine. We are now within ten days' sail of Malta, which suffered from plague in 1813. Malta is now within six days' sail of Alexandria, the capital of Egypt, which has ever been the faithful mother of *pestilential disease*. The plague of Athens, of which Thucydides gives us so vivid a description, was imported from Egypt in vessels which laided at the Piræus, and from thence depopulated Greece. The mortality from yellow fever on board the *Eclair*, in one of our own roadsteads, clearly proves that the scourge of Africa can propagate itself in the temperate climate of Britain, and while we keep up at an enormous expense of human life and treasure, a blockading squadron along the African coast, in the vain hope of exterminating slavery by such means, it is very possible at some future period, the fever of the Niger may locate itself for a while on the banks of the Thames. The oscillations of human opinion when blind self-interest dictates the conclusions, are remarkable. The wisdom of modern times deduced from ancient experience dictated those laws of quarantine which have long protected Europe; but the mercantile world, in its lust for rapid accumulation, has employed medical talent to disprove the logic of history and human experience. The frequent irruption of pestilence in the Roman dominions, the contagious epidemics of the middle ages, the importation of the plague in 1728, at Marseilles, with the fearful mortality which accompanied it, are lessons which, for modern writers on contagion seem to have been written in vain. The "Asiatic Cholera" at the present time seems the cloud which is lowering in the distance and ready to burst upon us. With so many sources of infection from all parts of the northern hemisphere, from Alexandria to Siberia, it appears too imminent for our feeble quarantine resources to keep from our shores. It has already reached our out-ports. Are we to act as if no danger from contagion existed? I would ask—not in how many instances has an imperfect quarantine* allowed it to slip between its fingers, but in how many instances has its spread been arrested?

But some may perhaps be ready to say have we not a "Board of Health;" and have they not begun by an order of Council putting the whole country under the "Nuisances Act?" It is a very good beginning certainly, but I must confess that I have not much confidence in this "Board of Health." My Lord Morpeth, (now Earl of Carlisle,) and my Lord Ashley, may be very good politicians, and yet very unfit from their education as statesmen, to constitute such an important and peculiar body as a "Board of Health," *without a much larger number of medical men than they have hitherto thought proper to associate with them.* They may be amiable and accomplished gentlemen, of business-like habits, and of most excellent private character, but on that very account they are more likely to be led by the nose into the commission of many medical errors. The men they have chosen to make medical members of their Board of Health, are not in sufficient number, nor are they perhaps the men whom the professsion would have chosen and have put confidence in. They appear to be all non-contagionists. It was the morbid idea of the late Duke of Bridgewater, I believe, that our rivers were only adapted to feed navigable canals; our "Sanitary Commissioners" seems to be of opinion that they ought all to be converted into main-sewer drains. No wonder the Serpentine is poisoned so that men are afraid to bathe in it. In a short time, if all the foul matters from two millions of people are poured into the Thames, that too will become a pestilential ditch; besides involving the annual loss to the community of many millions of pounds of human guano. The two volumes on the table are called the "Report of the Sanitary Commissioners," and this report is signed by Lord Grosvenor, a very respectable nobleman, not unknown to our county; and by Mr. Owen, a fellow

* Since this was written, quarantine regulations have been suspended. The cholera had been raging at Hamburgh nearly five weeks before any vessels from that port were put under quarantine. After several cases had occurred at Hull quarantine restrictions were begun. They have, since the cases have become more numerous, been entirely removed. The door was locked when the steed had been stolen; and I suppose the wisdom of our Board suggests they may as well be hung for a sheep as a lamb.

student when I was at Bartholomews', who has since occupied his days and nights in the dissection of dead animals of all kinds, and the reconstruction of fossil skeletons, in which he has shewn a remarkable genius for accurate description, careful generalization, and original discovery, only surpassed by his predecessor in palæontology, the illustrious Cuvier.

Epidemic diseases and city-draining are subjects, however, in which Mr. Owen cannot pretend to stand as any authority; and it was certainly cruel to deprive the College of Surgeons of so valuable a professor during the period in which this Sanitary Commission was concocting its two volumes. Odontography and comparative anatomy must have suffered for it amazingly; but what between the time he lost in tracing out the potato disease in Ireland, from which Commission I imagine the public had the felicity of learning nothing, and the time this year sacrificed in architectural studies respecting the best shape of drain pipes and effluvia traps, as well as the laws of epidemics, I fear pure surgery, for which the College professes itself to be instituted, will reap but little advantage from the lucubrations of their peripatetic philosopher. We think the adage, "ne sutor ultra crepidam," would have been a good maxim; yet it seems, notwithstanding the pure surgery of the College, Mr. Owen appears to have been a very "general practitioner" in the "general Commission" line. But it may be said, in addition to my Lord Grosvenor and Professor Owen, there were Dr. Southwood Smith and Mr. Commissioner Chadwick. The latter is a barrister, very active and talented, no doubt, but knowing practically about as much of fever and cholera, as Mr. Owen does of engineering. Whatever respect we may have for the authority of Dr. Southwood Smith, we must confess that he has always had a favourite hobby, and has been somewhat too speculative and crotchetty* to be implicitly followed.

The venerated names of Dr. Copland, Dr. Paris, Dr. Latham, Dr. Watson, and many others easy to name, would have given such a document considerable weight,—why were not at least such men examined? The winesses of whom inquiries appear to have been made, were all selected with a *one-sided object*, which gives the whole document not *the aspect of a search after the truth*, but the evident appearance of *making out a case*.

When we consider the efficient organization which a county society like our own is capable of evolving.—that by means of its members distributed in every part of our county, how easily we may communicate through the secretary a monthly report of the rise and progress of epidemic diseases within a given space, (which the secretary may, without much difficulty, tabulate and arrange,) I think it must be allowed that we have an opportunity afforded us of throwing light on the course and character of epidemics, which the crowded population of our large towns does not afford. If, for example, we could track a given epidemic from family to family, and from village to village, carefully noting its progress, and reporting the results at definite short periods, not by the mortality, which is the only criterion of the Registar-General, but by the *numerical lists of cases*, with *the treatment annexed*, I am sure we should do much to throw light on important points now involved in much obscurity.

It was a valuable suggestion thrown out by Dr. Conolly, in the first year of the existence of the Provincial Association, which the broad basis and extensive character of that body has hitherto prevented from being carried out, but which your county Society gives a fair opportunity of realizing. The Asiatic cholera will afford us an instance in point. Suppose it be found that on a certain day a case of suspicious choleric diarrhœa and fever appears on board a vessel in Poole, lately arrived from Hull or Sunderland, followed a few days after by several fatal cases, but that ventilation, cleanliness, and quarantine, arrest its further progress. Suppose in another town a man arrives just sent out of a cholera hospital from London, that he has a relapse of diarrhœa, attended with the choleric fever, and that he, as well as two inmates of the same house, are carried off without extending the disease further, may we not learn something from such a narration, as well as from the fact of its having appeared in Aleppo, and carried off 20,000 victims, or at Bilston, and swept away 900? Yet such facts as these did occur, and were unrecorded in the last invasion of cholera, in 1832. Should we not be able to deduce some important practical conclusions, first as to the length of time necessary to form a sufficient quarantine, and, secondly, should we not be able to lay our fingers on certain localities, and be able to say, here cholera appeared and was arrested by certain *preventive measures*, arising from the suggestions of a cautious belief in its *communicable character*. I must confess that the doctrine of the non-contagionists appears to be equally rash and mischievous, as regards the arrest of the cholera, as the doctrine of fatalism among the Mahomedans is with regard to its cure.

But I am not now arguing the question of the contagious or non-contagious nature of cholera, which I will reserve for your consideration by and bye; I am alluding to the importance of employing the organization of county Associations of medical men, for the purpose of throwing further light on questions upon which differences of opinion are entertained, and in which a dangerous kind of uncertainty is often the result. I may mention the course and progress of typhus fever, as another instance in which there are many delusions which might be cleared up by local observations over a carefully-watched area like Dorsetshire. With regard to typhus fever, I may just mention a few facts which may, perhaps, be of some interest now Sanitary Commissioners appear to have lost sight altogether of the spread of diseases by contagion, and attribute all

* Among the crotchets of Dr. Southwood Smith we may notice the following extract from the fifth Annual Report of the Poor-Law Commissioners Appendix.—(c. No. ii.) Dr. Smith says, "Although scarlatina is usually arranged by medical authors under another class of diseases, namely, that termed exanthemata, or the febrile rashes, yet I have included it under continued fever, because from a long study of the phenomena of the disease during life, and an extended examination after death, of the morbid changes produced by it in the internal organs, I am satisfied that it *differs in no essential character from continued fever.*

epidemics to cess-pools and defective drainage. About two years ago a man died of fever; his wife and family soon after his funeral were removed to their parish. They then fell ill of "low typhus;" those who nursed them took the disease, and communicated it to their families. Upwards of fifty cases fell to my share of attendance between February and November, when the disease appeared to burn itself out for want of more subjects susceptible of taking it. Men, women, and children of all ages, took it, some severely, some mildly. A few had symptoms of "typhus gravior," proving them both to be the same disease, modified by the subject. To my certain knowledge typhus fever had never visited this parish epidemically for twenty years, the drainage had been equally bad for twenty years previous, and yet no wet season had produced fever during the whole of that period. The disease was *then evidently imported*; it extended to all who had constant communication with the sick, except those who were protected by natural insusceptibilty, or by having had the disease before.

If we could accumulate a body of such facts as these, which may be fairly hunted out in our own county, we might throw some light upon the laws of contagion, which from the virus being more or less diffusible in the atmosphere, may *vary in different epidemics*. I think we should find that fever in the country takes up its residence in new quarters, and travels, like the fungi in the fairy rings, always over new ground, or else dies out for want of victims within its reach; that though it may be more rife than usual in some unwholesome seasons, yet that it lurks in almost every month of the year, through spring, summer, autumn, and winter; that like small pox and scarlet fever, though now and then more violent than usual, it still follows the same laws of contagion, and requires the same system of separation and quarantine; and that we can generally expose with impunity those who have gone through the disease fairly before. Our scattered members may track their fever trails with the greatest ease, and while our brethren in crowded cities, like the huntsman in a rabbit warren, are only puzzled by a variety of cross scents, we may, by comparing notes with different parts of the county, have the same knowlege of the track of epidemics as the detective police obtain of those who transgress the laws.

The Sanitary Commissioners pretend to say, that in certain localities of a low and filthy character, fever is always prevalent. They should have added the fact, that in those localities the population must be dense and ever-changing, *an important element in the question*, for I am quite sure your village experience must teach you that fever enters a locality, rages for a while, and perhaps decimates the population, and does not return for twenty or thirty years as an epidemic, until another population has grown up who have not been protected in some degree by having previously suffered from the disease. The pestilential cholera, which has been with a few variations pursuing the same course through the north of Europe that it took in the year 1831, has for some weeks raged at the same seats of commerce, Riga and Hamburgh, from which it was imported into this country, *viâ* Sunderland, in November, 1831. It now appears to have reached England; Hull, Sunderland, and Edinburgh, have reported a few cases to the Board of Health. How far it may extend it is of course impossible for us to foresee, but the same laws which regulated its march in 1831 and 1832, are still in action. The disease is identically the same in its features and its fatality, and the experience of the last inroad gives a pretty clear view of the probabilities of its future course. It then, as now, broke through the *imperfect* and *too late* quarantine regulations. It appears this year that no quarantine was established till after the occurrence of several cases. Introduced into this country among so dense a population in constant intercourse, it seems impossible for human efforts to prevent its dissemination. In preparation for its approach, certain Acts of Parliament have passed the Legislature, which may become valuable. Although men's minds have been directed to the study of the public health with increased zeal for the last few years, public hygiène must, I fear, be considered quite in its infancy; men are suffered to congregate in our large towns in filthy, narrow, and ill-ventilated streets; the proper drainage of few towns has been completed, and the poor are crowded together, not only in the cellars of large towns, but even in many of our villages, in a state of beastly proximity, to which the well-informed agriculturist would not subject his prize cattle or his well-fattened pigs.

I must confess, gentlemen, I have read with some surprise, the hasty assertions of the Board of Health, published on Friday last in the *Gazette*, and since copied into all the journals. It states:—"The extent, uniform tenor, and undoubted authority of the evidence obtained from observers of all classes, in different countries and climates, and amidst all varieties of the physical, political, and social conditions of the people, appear to discredit the once prevalent opinion that the cholera is in *itself* contagious,—an opinion which if fallacious must be mischievous, since it diverts attention from the true source of danger and the real means of protection, and fixes it on those which are imaginary, creates panic, leads to the neglect and abandonment of the sick, occasions great expense for what is worse than useless, and withdraws attention from that brief but important interval between the commencement and the development of the disease, during which remedial measures are most effective in its cure." The question of the contagion of cholera, "in itself" or "out of itself," we cannot deem quite settled by a statement made in this *ex cathedrâ* fashion; neither can we bow to the infallibility of this newly-constituted secular authority, which disposes so summarily of the conclusions of the Board of Health of 1832.

Is it not, gentlemen, a very strange anomaly, that this "Board of Health" of 1848, should thus boldly proclaim that the Asiatic cholera is not a *contagious disease*, and should have thought proper at the same time to put the whole country under, what has been called, the "contagious diseases" Act! It may be said, perhaps, that to prevent alarm, and to secure to the sick the

ready assistance of zealous nurses, they have thought proper to declare the cholera to be non-contagious. In this country such a declaration is not necessary to procure ample attention to the suffering patient; neither do we think it will lessen the terror in the popular mind. In Russia, where similar declarations have been made by the public authorities, it has not prevented a panic among the inhabitants of St. Petersburgh, from which place thousands have fled into the surrounding country, and many have perished from famine, who ran away from the pestilence. In India, notwithstanding the general opinion which existed of its non-contagious character, it has been, and is, the common practice, for the poor people to fly in all directions into the adjacent jungles, and oftentimes to leave their sick, uncared for, to perish by the way. We contend, then, that such a declaration, even if it be true, does not lessen panic, and does not facilitate the care of the sick, but is likely to prevent due measures of quarantine and separation from being taken; and by throwing people off their guard on its first importation, may disseminate the disease more widely than even on the last occasion in which it visited this country. We cannot, on the bare assertion of a Board of Health, unlearn the experience of the past, and falsify the conclusions at which the highest authorities in the profession had arrived, after a careful examination of the rise and progress of this disease since it first entered Europe in 1830.

Mr. Orton, an Indian practitioner, of the most extensive knowledge of this disease, after first holding the opinion of its non-contagion, has published in his valuable work on the cholera, the indisputable facts on which he bases his decision of its infectious character; Dr. Watson, in his able lectures on medicine, taught the same doctrine; and Dr. Copland, in his gigantic work, the "Dictionary of Practical Medicine," has gone through this enquiry with the most patient research, and has produced the most ample and irrefragable evidence of the contagion of pestilential cholera. The careful perusal of his article "On Cholera-Pestilence," will amply repay the most patient attention. This article has hitherto been unanswered, and is, in fact, unanswerable.

It would have been much wiser, we think, had the Board of Health, (notwithstanding the authorities upon which it has based a contrary conclusion,) abstained altogether from expressing an opinion on the subject, and had imitated the cautious advice of Sir Thomas Munro, who, when dying of this disease in India, found his bed surrounded by a crowd of anxious friends who were of no service to him. They said they had no fear, as the disease was not contagious. "Ah!" said he, "that is an unsettled question; you had better be on the safe side, and leave me."

While some persons, who have thought proper to deny the infectious character of the "Asiatic Cholera," disseminate all sorts of absurd though ingenious theories to account for its spread over the globe, and whether it be electrical action or defective drainage, amuse the community with all sorts of wild speculations, we confess ourselves to be simple-minded enough, to be satisfied with the philosophical logic which contents itself with one efficient cause, *modified of course by local circumstances, and atmospheric conditions.* We observe the analogy of other pestilential epidemics, and witness in the small-pox an animal poison, capable of a certain definite diffusion in the atmosphere, and a certain absorption and retention in the garments and bed-clothing of the infected. This we consider quite enough to account for its dissemination in all the four quarters of the globe, without troubling ourselves about electro-magnetic phenomena, or any other of those atmospheric vagaries, with which *post hoc, ergo, propter hoc* reasoners, may choose to inundate the press.

If it be said that in small-pox you can take up the infectious particle on the point of your lancet from the skin of the sick man, I would point to another animal poison of an analagous, though in some respects dissimilar, character, which does not less exist, though you cannot seize it between your fingers,—I allude to the poison of scarlatina. Although we are well aware that crowded and ill-ventilated dwellings, and the absence of cleanliness among the poor, aggravate the intensity, and increase the fatality, of these animal poisons, would it not be absurd in us to put down these as the efficient causes of the diseases in question, when they have existed for ages without producing any such effects? It is quite within the memory of man, when the measles first appeared at the Cape of Good Hope. In 1517 the small-pox was first imported into St. Domingo; yet Rhages, the great Arabian physician, who gives the earliest account of small-pox now extant, imagines it to be a disease which arises from the spontaneous fermentation of young blood, and that it was a necessary disease for all mankind to pass through, produced spontaneously in the system during certain unhealthy seasons. He must have observed its course and progress for many years, and yet he says not a word of its being communicated from one person to another. Even Sydenham himself says nothing of the contagious nature of small-pox; and it seems rather questionable whether the partisans of non-contagion would not have denied infection in small-pox, had not the practice of inoculation originated, which Dr. Mead appears to have first practised in England upon some criminals condemned to death in one of our gaols.

It is thus very apparent that medical men may be blind to the contagious property of a disease, when they are unable to produce it by inoculation; no wonder, then, the earlier practitioners in India, in the thickest of the storm, could not see their way, and generally denied the contagion of the cholera. Their slow and reluctant assent to such an opinion was forced upon them by the calm observation of facts. The individual experience of each was insufficient, but when generalized and investigated, such men as Kennedy, and Orton, and Copland, were led to re examine the question, and reverse their earlier decision. Who could have been more patient investigators of the disease than Sir David Barry and Dr. Russell, who watched its progress in St. Petersburgh, and were the principal medical members of the Board of Health of 1831? Is the *ipse dixit* of Dr. Sutherland and Dr.

Southwood Smith, or Mr. Grainger, to upset the close investigations of such men?

We are not able to discover that any new facts have arisen respecting cholera, either with regard to its course, progress, character, or treatment. The duration of the disease when it has attacked any place has been similar, and its advance in the same lines of commerce and human intercourse, taking about the same period to travel, in spite of opposing winds, and every variety of atmospheric conditions. The only difference has been in a somewhat more rapid march from place to place, corresponding with the increased facilities of locomotion, and in some degree, perhaps, to be accounted for, from the abolition of all attempt at forming a "*cordon sanitaire.*"

We do not think that the avowal of the truth, either with regard to this disease, or the plague itself, is likely to be productive of mischief, but on the contrary, may induce wholesome measures of precaution, which in thousands of instances have been employed with success in preventing the spread of these maladies. We know, gentlemen, (for we saw some of the cases,) that in the little village of Bere, in this county, there were, in 1832, twelve cases of genuine Asiatic cholera, of which six proved fatal; that the first case was that of a person who came from London. It did not extend into any adjacent village. What general cause could have acted on the little village of Bere, which was not at the same time acting on the district by which it was surrounded? When the cholera was at its height in the city of Exeter, I took the opportunity of visiting it for the purpose of observing the disease, and with some of the medical men there, for several days, I saw patients in every stage, in the worst parts of the city. I saw no want of attention to the sick on the part of medical men or nurses, and the cases were attended to most promptly and efficiently, notwithstanding the general impression of the infectious character of the disease. I must, however, state that the worst cases I saw in the fatal collapse, were those who neglected sending for medical assistance till some hours or days after diarrhœa had commenced. It was a curious circumstance related by Dr. Shapter, in the "Transactions of the Provincial Medical and Surgical Association," that the two first cases which occurred in Exeter, came from two infected places, London and Plymouth, after which it spread to such an extent that 400 of the population died, and yet he says that none of the adjacent villages were visited by the epidemic, Topsham, Dawlish, and Crediton, having only a case or two, which did not extend further. We would ask how often have small-pox and scarlatina raged in Exeter without extending to Topsham and Dawlish? Do you doubt their contagious property on that account?

A few cases occurred at Poole and at Bridport in this county, but strict attention to cleanliness, ventilation, and those cautions suggested by a general belief in its contagious properties, contributed very much to arrest the further progress of the disease.

And now, gentlemen, in conclusion, I would briefly allude to the practical advice we would give our towns and villages on this important question. We say, then, let Boards of Health or Committees be constituted in every town and village, and let them at once commence a careful investigation of all nuisances, with a view to their removal, by the means afforded by Vict. 11 and 12, cap. 123. To the owners and occupiers of cottages we would advise an examination into their internal state of cleanliness, whitewashing and cleansing where necessary, removing dung-heaps, and attending carefully to the proper ventilation of the sleeping apartments. To the poor themselves, the various medical officers will no doubt make known the necessity of warm flannel clothing during the winter, and the earliest possible application for medicine in case of any loose state of the bowels. It will suggest itself to each one of you, that cordial opiate mixtures, or some pills of calomel and opium, might be left with some confidential party in every village, to which resort may be at once had in cases of diarrhœa. We do not think any further tampering or quackery is desirable. The constant employment of the resident poor, at a rate of wages sufficient to afford their families ample clothing and substantial nourishment, in which animal food shall form a fair proportion, is one of the best prophylactics for an agricultural county like Dorsetshire. The careful superintendence of tramp lodging-houses, and the strict enforcement of the laws against vagrancy form an important feature in the duties of Boards of Guardians and Justices of Peace.

We would add, also, the propriety of establishing in connection with every union workhouse, some separate ward or building, which should be appropriated for the reception of all tramps and others who may be affected with cholera, typhus, or any other contagious disease. Our general immunity from cholera at the period of its last invasion arose probably from the *fear of contagion inducing strict measures of separation and cleanliness*, as well as from the comparatively small population of our towns and the scattered character of our villages, and the "*cordon sanitaire*" of our cultivated fields and belts of downs. We are disposed to add, that the water of our chalk districts, impregnated as it is with the carbonate of lime, in all probability rendered our population less susceptible of diarrhœa—the great premonitary symptom. The localities of chalybeate springs appear both in this country and in Germany, to have had in some degree a similar prophylactic influence.

We do not anticipate that any very formidable irruption of the disease in this county will attend the present epidemic, for the same sources of protection still exist. Should, however, a more general invasion of cholera await us than in 1832, the activity and zeal, and medical knowledge of the practitioners of the county may, I am sure, be relied on, to obtain all those ameliorations of its severity which human skill and attention are capable of affording.

Although medical aid appears to be so fruitless in the last stage of the Asiatic cholera, nothing is better ascertained than its value in the earlier symptoms. In India the Medical Board of Bombay report,—"There is reason to believe, that of 1294 cases which received no medical assistance, every individual perished."

The sooner the premonitory diarrhœa is stopped, and the earlier our resources can be brought to bear, the less everywhere becomes the mortality. We believe the fact to be indubitable, not only from Indian, but from European statistics; and the more men's minds are enlightened as to the necessity of sanitary measures, and the removal of nuisances, the better chance we have in arresting the progress of the formidable epidemic. It is not only thus with cholera, but with all other epidemic diseases. Filth of all kinds appear to be the appropriate soil or nidus of contagion. Fresh air, ventilation, and cleanliness, moderate the virulence of every febrile disease; so that we could almost pardon the exclusive attention which even our sanitary commissioners appear to have given to this element of the question, if truth did not demand a more candid avowal. The facts proving the cholera to be contagious or communicable from infected sources we deem to be irrefragable, but the rapid dissemination of that contagion which appears sometimes to have extended a very considerable distance from the primary source, and carried on the wings of the wind and along the banks of rivers, often baffles quarantine regulations, and has often leaped the barriers of the "*cordon sanitaire.*" We do not imagine the infection exists in a great degree in the stage of collapse, but the consecutive fever, and the fæcal evacuations, seem to be sources of the poison. The mouths of sewers, the low swamps bordering rivers, and the long occupied ground of camps, are always dangerous positions to inhabit, but when the disease has already made its appearance, are tenfold more hazardous. In the belief of its contagion, care should be taken to destroy or otherwise purify, by chlorine and afterwards boiling water, the bed-clothes and under garments of those who have been affected with the disease. The history of cholera shews us, for our comfort, that it cannot permanently take up its abode with us as it has done in India. It will die out after a short time; it is not like the small-pox and typhus fever, one of the indigenous or naturalized diseases of our climate. It is a foreign exotic, and the great majority of our northern constitutions are not susceptible of the disease in its most malignant form. It is, then, a *transient* epidemy; it now re-appears after an absence of nearly sixteen years. By a careful study of its laws of propagation, as well as the best means of alleviating its sufferings, we shall be fulfilling our high duty. The mercantile world may hug its delusions, which "Boards of Health" and leading articles in the *Times* may please to foster, but the medical profession will not sacrifice the truth of any well-established conclusion on the mere *ipse dixit* of a few zealous partisans. We know the infection of small-pox was not noticed by *ancient observers*, and the contagion of the plague has *been denied* by *modern writers*; we are prepared, therefore, for the most *broad assertions* with regard to cholera. Facts, however, are stubborn things, and there is a force in truth which at length overcomes all fallacies.

ON THE

TREATMENT OF RHEUMATIC PARALYSIS BY ELECTRO-MAGNETISM.

By William Davies, M.D., Physician to the Bath United Hospital.

(Read at the Bath and Bristol Branch of the Provincial Medical and Surgical Association.)

Mr. President,—

I purpose, on the present occasion, to bring under your notice the case of an individual who had suffered for many months under rheumatic paralysis of the hands and lower extremities, and in whom power over her limbs became restored under the use of electro-galvanism.

I will, in the first place, detail the case, and, secondly, offer a few fragmentary remarks on the agent employed in the cure,—namely, electricity, in its relation to living beings.

Case.

Jane Farley, aged 25, had always enjoyed good health; had been accustomed to work in a laundry, in which occupation she was much exposed to cold and damp. Previously to the illness of which I am about to speak, she had never suffered from rheumatism. In December, 1845, her hands began to swell, and she gradually lost the power of using them, but suffered very little pain. The swelling and weakness continued to increase until February, at which time she was admitted into the United Hospital, under the care of Dr. Bealy. She remained under treatment eight weeks, when she was discharged greatly relieved, the swelling of the hands being much diminished, and the power almost restored. She returned to her occupation of laundress. The improvement was only of three weeks' duration, when the affection of the hands returned, accompanied at this time with swelling, pain, and weakness of the feet and knees.

In August, 1846, she first came under my care as an out-patient of the United Hospital. At this time she was in the following condition:—The joints of the hands, feet, and knees, much swollen, and exquisitely painful to pressure. She was unable to walk across a room without assistance, and she had so little use of her hands, as to be unable to dress and undress herself without aid. Her skin was covered with a cold clammy moisture, of a sour odour, and a strongly acid reaction on litmus paper. She suffered much from irritability of the stomach and bowels, in the form of acid eructations and diarrhœa; there was considerable epigastric pain and tenderness, especially after taking food; the ongue was red and pointed, the papillæ at the point being large and prominent; the organ was also covered here and there with thin patches of creamy exudation, through which the red raw-looking mucous surface could be distinctly seen. The pulse was quick, and of small volume; menstruation was rather profuse.

The treatment at this time consisted chiefly of sedatives and antacids. She seemed to derive more benefit from a mixture of hydrocyanic acid and bi-carbonate of potass in water, than from any other remedy tried; she took four minims of the one, and

ten grains of the other, every four or six hours, according to circumstances. Under this treatment her general health improved exceedingly, and she got rid of the troublesome gastric symptoms under which she had laboured at the commencement, but the power over her limbs remained very much *in statu quo*.

On the 9th of October, I admitted her as an in-patient, and she remained in the hospital nine weeks. She was only, however, under my observation the first two weeks of that period, in consequence of my being confined to the house through indisposition, during the remainder of the time; I therefore pass over that period, merely observing that she left the hospital with even less power over her limbs than she possessed on her admission. On quitting the hospital, in the second week in December, she took to her bed, from which she did not move otherwise than as she was lifted, until the 5th of March, 1847, when I again admitted her as an in-patient of the hospital. Her condition at this time was much the same as I have already described, except that she had totally lost all power over her limbs. She was unable to stand without assistance, and could not hold anything in her hands. She remained in the hospital fourteen weeks, during which time she was subjected to various treatment, the details of which would occupy too much of the time of the meeting; this, I may say, however, that each step of the treatment was adopted after as careful consideration as I was able to bestow upon the case. The common warm bath, and subsequently the vapour bath, were fairly tried; from the use of the latter she derived some benefit, was able, at the time she left the hospital, to stand without assistance, and even, on first rising from bed, to walk a few yards with the aid of some object on which to rest her hands. Her general health at this time was much improved.

From the middle of June, the time of her quitting the hospital, until the first week in August, she remained with her friends in a most helpless condition, quite unable to do anything for herself; she was then removed to an apartment near the hospital, with the view of trying the effect of galvanism in the warm bath. She was galvanized in the bath daily, with few exceptions, for a fortnight, at the end of which time she was able to walk from the place where she lodged to the hospital, and back again, a distance of 300 or 400 yards, an exploit she had not previously performed for more than eighteen months. At this time the application of the galvanism was arrested for a month, in consequence of the great inconvenience attending its use in the common slipper bath,—the only one at my disposal. During that month she retrograded to nearly her former condition, being unable to do more than walk across a room, and that not without difficulty and with support. On the 23rd of September, I was enabled again to have recourse to galvanism, in a bath admirably adapted for the purpose, through the kindness of Messrs. Green and Simm, the lessees of the baths. From this date she was galvanized daily, with the exception of the Sundays, for two months, during which time she improved gradually but rapidly, until it was considered no longer necessary to continue the treatment, from her recovery being complete. I am indebted to Mr. Tyler, chemist, of this city, for having taken off my hands the troublesome and laborious office of applying the galvanism. The apparatus used was the ordinary electro-galvanic. The application was continued at first for a quarter of an hour, but subsequently, during half an hour. She took no medicine of any kind while under treatment by galvanism.

I fear, sir, you will consider that I have been tediously minute in the relation of this case, but it seems to me an interesting and important one, and I think it advisable, whenever a case is adduced in support of the efficacy of any particular therapeutic agent, or line of practice, that the observer should state the case minutely, so as to place those who may hear or read it, as far as may be, in the same position as he is himself, in respect of forming a judgment as to the truth or error of the conclusion which the author has been led to form.

It is proper to call the attention of the Society to one point in the relation of the case, which seems to me to remove any doubt which might exist, as to whether galvanism really was the efficacious cause of cure, or only a mere co-incident. 1st. It could not have been the warm bath alone which brought about the cure, as full trial had been given it under similar circumstances previously, without any appreciable benefit. 2nd. That it was the galvanism, is proved by this; that under the first fortnight's application, great improvement took place; that all this improvement was lost during a month's suspension of the treatment, and that on its resumption improvement was again manifested, which went on under its continuance to a perfect cure.

The patient has returned to her occupation of ironer for more than three months, and now stands at her work during twelve hours a day, six days in the week. By the evening her feet become somewhat painful and swollen, as also her hands, but she told me within the last week that she was quite well, and that if she had it in her power to follow any occupation that did not involve so much standing, she should be as well as ever she was.

The above case illustrates sufficiently well the therapeutic influence of electricity in one form of disease,—namely, rheumatic paralysis of the muscles of the extremities, the great nervous centres remaining intact, and that this is the particular form under which we ought to expect benefit to arise from the use of electricity, perhaps, more than under any other, will, I think, appear from a short review of what we know concerning this agent, in its relations to living beings.

Professor Matteucci, of Pisa, to whom we are indebted for nearly all the precise knowledge we possess on this subject, has shewn that there is a constant current of free electricity traversing the muscles of all animals, even of man himself;—that the course of the current is from within outwards;—that the higher the animal is in the scale of being, the greater is the amount of electricity developed;—that any cause which has the effect of reducing the vital power of an animal, and impairing its due nourishment, diminishes proportionately to the extent of change, the intensity of the muscular current;—that immersion of an animal in

sulphureted hydrogen gas destroys the current altogether, and, on the other hand, that anything which tends to increase the development of muscular power, increases also the electric current in those muscles.

It has been observed by Pfaff and Ahrens, and also by Humboldt, as will appear from the following quotation from "Müller's Physiology," that in rheumatic affections the electricity of the body is at zero. They say:—"During the continuance of rheumatic affections the electricity of the body seems to be reduced to zero, and to become manifest again as the disease subsides. It appears to Humboldt also, that rheumatic patients had an insulating action on the feeble current produced by a simple galvanic circle."

It has been shewn that muscles lose their power of contraction when the current of blood towards them is obstructed; this has been observed in the human subject after ligature of a large arterial trunk in the muscles supplied by that vessel, and also in the hinder extremities of animals after ligature of the abdominal aorta. Müller, speaking of the influence of the blood on the contraction of muscles says,—"It is therefore certain that the arterial blood undergoes in the motor organs, a change, which, while it gives the blood the venous character, renders it unfit to maintain in the muscles their contractile property,—in other words, that the property of contractility requires for its perfect preservation the constant action of arterial blood on the muscular fibre."

Now, Davy and Faraday, among their numerous additions to physical science, have proved this—that wherever chemical action takes place, there free electricity is produced; in fact, that chemical affinity and electricity are identical powers. Liebig has shown that if fresh muscular tissue be cut small, and macerated in distilled water, it gives an acid reaction on litmus paper, and this, notwithstanding the large quantity of alkaline blood contained in its vessels, thus proving a secretion from the capillaries of an acid nature; so that in muscles there exists an alkaline fluid within the vessels, and an acid fluid without, a moist animal membrane intervening,—a condition of matters which has been abundantly proved capable of producing chemical action, and, consequently, of setting free electricity.

Now, from what has been said it has been shown:—

1st. That there is in all muscles a constant current of free electricity.

2nd. That the intensity of the muscular current bears a direct ratio to the vigour of the animal, and the degree of development of the muscular structure.

3rd. That immersion of an animal in sulphuretted hydrogen gas destroys the current altogether.

4th. That in rheumatic affections, the electricity of the body is at zero, but becomes manifest again as the disease subsides.

5th. That a constant supply of arterial blood is essential to the contractile power of muscles.

6th. That wherever there is chemical action, free electricity is developed.

7th. That the conditions of chemical action exist in muscles, by means of the alkaline fluid within, and the acid fluid without the vessels.

Analogous to this last head, and confirmatory of its truth, is an experiment performed by Aldini, at Guy's Hospital, in 1803, in which he took the prepared leg of a frog, and held the extremity in his hand, previously well moistened with salt and water, while he allowed the free end of the sciatic nerve to touch his tongue; contractions of the muscles of the frog's leg were immediately produced, thus proving the existence of an electric current passing between the internal and external surface of his body. See, for further details, Dr. Bird's "Natural Philosophy," or his lectures before the College of Physicians, in 1847, published in the *Medical Gazette*. Donné, in the "Ann. des Sciences Nat." for February, 1834, gave the explanation of this experiment, by referring it to the different chemical conditions of the integument of the body, and the mucous covering of the alimentary canal,—the one being acid, and the other, for the most part, alkaline, meeting at the mouth, nostrils, and anus. It will be seen that this condition is similar to what has been already mentioned as existing in muscles.

Now, if we keep before us the various facts I have adduced, and venture on an attempt at their estimation, the following may, perhaps, appear not altogether unreasonable:—

1st. We have the fact of a constant electric current in the muscles of all animals. What are the conditions which diminish this current? 1. A low position in the scale of living beings. 2. Imperfect development of the muscular structure, with depressed vital powers. 3. Immersion of an animal in sulphuretted hydrogen gas. 4. A rheumatic condition of the system. All, (it will be observed,) circumstances in which the free action between the arterial blood, and the muscular fibre, is either interfered with or destroyed, and all circumstances which impair the contractile power of muscles.

2ndly. What are the conditions which increase this current? Everything that is the opposite of the above; high vital powers, full development of the muscular structure, in fact everything that promotes the free action between the arterial blood and the muscular fibre,—everything that is essential to powerful muscular contractions.

These facts seem to point to a very close relation between muscular contractility and electricity, if they do not go far enough to shew that the one stands to the other in the relation of cause and effect; and they certainly furnish a very strong theoretical reason, anterior to all experiential evidence, in favour of electricity as a remedial agent in certain forms of impaired muscular contractility.

It would be irrelevant to the matter in hand to enter into other relations which probably exist between electricity and vital actions, besides which we should be in danger of losing ourselves in the mists of speculation; this, however, I may be allowed to say, that I believe no department of science offers to the medical philosopher a more worthy subject of study than that which I have attempted to bring under your notice this morning.

CASES OF OXALURIA.*

By P. Martin Duncan, M.B., Physician to the Essex and Colchester Hospital.

The three cases about to be described were nearly as difficult to relieve as those reported in a former number were easy of cure.

Case IV.

Anne Stradling, aged 36, married, and the mother of several children, was admitted as an out-patient in the Colchester Hospital, on July 23rd. She attributes her ailments to having caught cold, and subsequent acute rheumatism, by exposure to the night air, about a year ago. Before that time had always robust health. She is a middle-sized woman, with the appearance of having been much stouter than she is at present. Complains of constant frontal headache, a sensation of weight and uneasiness in the loins, and pain in the right side, not extending to the shoulder. She has very low spirits, and trembles violently after the slightest exertion; complains of profuse acid perspirations, and of frequent heart-burn. Her face has an anxious and discontented appearance, and her lips and fauces are pale; tongue large, tremulous, furred, and transversely fissured; she sleeps badly; has generally little or no appetite, although at certain times she eats voraciously. No cough nor palpitation; the heart's impulse and sounds are normal; liver slightly enlarged; uterine functions regular. Never had syphilis nor ague; bowels regular.

Ordered her a mixed diet, and to eat but little at a time. R. Pil. Hydrarg., gr. iij.; Extr. Coloc. Co., gr. viij. Fiat pil. ij., alt. noctibus. R. Infus. Gent. Co., oz. j.; Ferri. Sulph., gr. ij. M. Capt. ter die.

July 30th. Obtained some of her urine, which was passed before breakfast; it was pale, of specific gravity 1012, slightly acid, and contained urate of ammonia and mucus; no oxalate. Ordered her to bring some urine passed in the middle of the day and to continue her medicine.

31st. Urine acid, pale, of specific gravity 1018, contained a considerable quantity of oxalate of lime, in octohedral crystals, much epithelium, and amorphous urate of ammonia.

Pil. Hydrarg., gr. v., alt, q. nocte. R. Acidi Nitrici, Acidi Hydrochlor., utrq, m. iij.; Infusi Quassiæ, oz. j. Sum ter die.

Aug. 7th. Says she has not been so well for months.

14th. Much the same. Cont. mist. Omitt. pil.

21st. Her general health is better, the pain in the loins, however, persists. She complains also of weariness after slight exertion. Tongue clean; bowels rather irregular; urine increased in quantity, specific gravity of a portion passed at noon, 1012, pale, acid, and containing the largest crystals of the oxalate of lime I ever saw. Her lowness of spirits is not so bad as it was, nor does she complain of her former severe headache. The appetite is more regular, but she complains of a sensation of weight and distension of the right side soon after taking her meals.

R. Acid. Nitric., m. iv.; Acid. Hydrochlor., m. v.; Inf. Quassiæ, oz. j. Misce. Sum ter die. R. Pil. Hydrarg., gr. iij.; Extr. Colch. Acet., gr. ij. Misce. Fiat pil. j., alt. q. nocte sumend.

28th. Is better.

September 4th. Complains of pain in the loins and weakness only. She has improved very much during the last fortnight; mid-day urine, of specific gravity 1024, acid, contained large crystals, in masses, of uric acid, little mucus, and no oxalate of lime. Pergat.

18th. No oxalate, but the quantity of uric acid excreted in the form of palpable masses of sand is very considerable. The pain in the loins persists; tongue rather foul; bowels confined.

Omitt. med. omnia. R. Pulv. Rhei, gr. x.; Sodæ Carb., gr. v. Mist. Camph., oz. j. Sumat ter die.

24th. Is better; the quantity of the uric acid has diminished, and no oxalate present in the urine. Pergat.

Until the present time she has continued much the same, complaining occasionally of pain in the loins, and nervous feelings. She has never passed any more oxalate, but nevertheless her health has not much improved. Her diet is of very doubtful description; occasionally she has meat, and feels much the better for it, but her general food is bread and butter, or dripping. She lives in a malarious district, and has a good deal of mental anxiety. Taking these circumstances into consideration, I much doubt if she will ever be anything else but a confirmed invalid. Her case is interesting in a practical sense, for it shows the necessity of examining urine, in which we suspect oxalate of lime to exist, after a meal, and not before any food has been taken into the stomach. Her urina sanguinis never contained oxalate of lime, although it was frequently loaded with urates. She was always better after taking highly nitrogenized food, whilst fat and spirits, in but small quantities, increased her lumbar pain, and as far as I could judge, the quantity of oxalate. Another point in her case is, that when she ceased passing the oxalate, the quantity of uric acid in the urine was sensibly increased, and the exhibition of as large a dose of alkali as I dared to give her, had not much influence on its amount. The specific gravity of her urine rose as the oxalate left her, and now averages 1020. She passes less urine than she did.

Case V.

Mrs. Stevenson, aged 48, has been a patient for many months at this Hospital. When I first saw her, July 23rd, she was complaining of great debility, pain in the loins, oppression of spirits, and a great disinclination to take food. Her symptoms are occasionally exacerbated, and when this is the case, she suffers severely from constant nausea and sickness; her urine is then scanty, high-coloured, and offensive. I was fortunate enough to see her in one of these paroxysms. Urine passed after her breakfast was slightly acid, of specific gravity 1024, high-coloured, with an iridescent pellicle on its surface, and contained fibrinous coats of the tubes of the kidney, altered blood-corpuscles, epithelium scales, which contained but little fat, and crystals of triple phosphate, and amorphous and rather

* Continued from page 565.

pinkish urates. There was little doubt of her having a calculus in her kidney. I ordered her a hydragogue cathartic and an opiate for each night.

August 7th. I did not see her in the interval, but found her much better. She tells me that she has suffered from occasional attacks of sickness for years, more especially since her menses stopped. She has now pain on pressing over the left kidney; and on examining her urine, I found crystals of triple phosphate, and, rather to my surprise, oxalate of lime in octohedra; pulse 110; tongue clean; bowels regular; no appetite; she sleeps badly, and the pain in the loins is increased during the night.

R. Pil. Hydr., gr. v.; Pulv. Opii, gr. ½. Fiat pil. j., omni nocte sumend. R. Mist. Camph., oz. j.; Tinct. Hyoscy., dr. ss., ter die sumend.

28th. The report says she is better; appetite has returned; passes a good quantity of water, but her legs swell a little at night.

She continued under my care until very lately. She is not much better in spite of the absence of oxalate of lime in her urine; this was brought about by small doses of nitric acid, between the 24th of September and the 9th of October.

Case VI.

Charlotte Goodfellow, married, aged 47, has been an invalid for upwards of five years, and a patient at this Hospital since March 23rd, 1848. She came under my care in the last week of June; in the interval she had been treated for general debility, chronic cough, and amenorrhœa. She was evidently at the critical period, and her ailments were attributed to that cause. She took alkalies, iodine, and slight purgatives, and when I first saw her, what with defective diet, mental anxiety, and medicines of a rather depressing nature, she was considerably debilitated. She complained of constant pain in the head and back, of most distressing despondency, and inability to use the slightest exertion, without subsequent exhaustion. Her appetite was bad, tongue pale, and the general surface anæmic. She has a dry hacking cough, depending upon a relaxed state of the mucous membrane of the bronchi; sleeps badly, and has dreams of a frightful nature. Bowels tolerably regular; pulse quick and small.

Ordered to take porter, and as nutritious a diet as possible. R. Pil. Scillæ Co., Extr. Conii, utrq., gr. iv. Fiant pil. ij., omni nocte sum. R. Mist. Camph., oz. j.; Tinct. Scillæ, m. x.; Ammon. Carb., gr. v.; Tinct. Hyosc., m. xv. Fiat haust. ter die bibend.

July 3rd. Is a little stronger, but otherwise much the same. Pergat.

11th. Better. Her cough is very troublesome, and the bowels are rather confined. R. Pulv. Myrrhæ, gr. v.; Ammon. Carb., gr. ij.; Tinct. Opii, m. v.; Mist. Camph., oz. j. Fiat haust. ter die sum. Pil. Hydrarg., gr. v., omni nocte.

23rd. Is just the same; with the exception of her cough being relieved, she is just in the same state. I had attributed her headache and despondency to the anæmic state of her system, and that to the cessation of her menstrual flux. I now examined her carefully and found no organic disease of any kind. She brought me some urine, which she passes in considerable quantities, pale, acid, of specific gravity 1016, and containing an immense quantity of oxalate of lime. I changed her medicine and ordered,—Acid. Nitrici, m. iij.; Acid. Hydrochl., m. ij.; Infus. Quassiæ, oz. j., ter die. Linctus pro tussi.

August 14th. She has gradually improved.

On the 28th, I increased the quantity of acid, with considerable benefit to her, and on the 18th of September discharged her in a decent state of health.

The two last cases shew how this disease may be masked by symptoms which pertain to other lesions. In Case V., symptoms of renal disease, and in Case VI., those of disordered uterine function, accounted for the mental and physical depression. Oxalate of lime was found in both cases, and when removed the patients experienced considerable relief. It is sufficiently obvious, that the presence of the oxalate is but a symptom of hidden disease, not of the kidney, but of the digestive organs; for the urine does not at all times contain oxalate of lime; the patient may pass large quantities of it during the afternoon, but none before breakfast; none before new matter is assimilated and received into the system, but much a little while after. It would seem, then, that the oxalate is derived from the products of primary and not of secondary assimilation; from food taken in, and not from the destructive process that is constantly going on in the tissues. Oxalate of lime is not excreted from the kidney in a direct manner; it is passed as oxalate of ammonia, crystals of which are occasionally met with, but the oxalic acid of the compound, has a great affinity for lime, and readily precipitates it from all its combinations with acids. Now, oxalate of ammonia has to be eliminated by the kidney, and has to come in contact with an urinary salt, of which lime is the base. It is more than probable, that it is, under certain circumstances, excreted instead of urea; that although this last usual urinary element may exist in the urine in considerable quantities, still oxalate of ammonia may replace a portion of it, and in some cases nearly all of it. Dr. Bird has drawn up a formula, which shews that, one atom of urea and two of water, after losing an atom of oxygen, become converted into oxalic acid and ammonia,—that is to say, if urea is existing in the blood, and is about to be eliminated by the kidneys, and any circumstances should arise which might have a de-oxidating effect upon it, oxalate of ammonia would be produced in its stead. Now, Liebig is in favor of the derivation of oxalic acid from uric acid. I do not see why it should not be produced from either urea or uric acid, as their chemical relations are very close.

The rationale of the presence of oxalate of lime, is probably the following:—A person habitually dyspeptic, of low vital energies, catches cold, or is subjected to some depressing influence, in the form of extreme mental and physical exertion, his food is not properly digested, the nitrogenous products are eliminated more copiously than is consistent with health, not in the form of urea or uric acid, but as oxalate of ammonia or oxalic acid. The vital chemistry of the kidney, on account of the general perversion of nutrition, and

some idiosyncracy which facilitates the occurrence of diseases of this organ, is not able,—has not sufficient power, to produce more than a certain amount of urea or uric acid; the remainder passes as oxalate of ammonia or oxalic acid, and either by double decomposition or simple affinity, becomes oxalate of lime.

Starting with this theory, in our treatment it is necessary to attend to the diet, clothing and general hygiène of the patient; to employ medicines calculated to elevate the standard of health, and which may at the same time act in a direct manner upon the disease. Tonics, stimulants, and mild purgatives will alone frequently relieve the distressing lowness of spirits and dyspepsia; but change of air and moderate exercise, and the exhibition of medicines which are supposed to produce a supply of oxygen in the system, will be found to eradicate the disease in the quickest manner. Nitric acid, with or without the hydrochloric, acts like a charm in removing the diathesis. It may be combined with a mild tonic and exhibited twice or three times daily.

ON THE

INTERNAL EXHIBITION OF CHLOROFORM IN CHOLERA INFANTUM, AND DYSENTERY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

A short time since you were so good as to insert a letter I addressed to you, on the internal exhibition of chloroform in spasmodic cholera, and believing that its beneficial influence in this disease arose from its remarkable power of soothing the irritation of the ganglionic and spinal system of nerves, I was led to hope it would exert an equally useful influence in dysentery and infantile cholera. The subjoined cases will, I think, prove that the opinion was not ill-founded. I have selected these from several others, not only because they were well marked, but as shewing that chloroform is a perfectly safe and manageable remedy, even when given to infants at the tender age of twelve or eighteen months.

About the middle of September last, the weather being generally sultry and humid during the day, the temperature becoming much lower towards the evening, cholera infantum and dysentery prevailed in an epidemic form in this locality, both affections assuming a very severe type, and evincing a remarkable obstinacy to treatment. In some cases of the former disease, spasmodic convulsions were frequent, and although opium was pushed in these cases, as far as it could be administered with safety to children of such a tender age, it neither controlled the diarrhœa, nor seemed to induce more than a temporary remission of pain. Under these circumstances, as recent experience led me to regard chloroform as an agent of great power in the cholera of adults, both in the malignant and simple form of the affection, it was resolved to put its influence to the test in two cases of cholera infantum, of a very severe character. In three cases occurring at the same period, the remedies employed prior to the use of chloroform, extending over a space of from four to seven days, completely failed to produce any alleviation of the symptoms; they must, therefore, be regarded as having been fair cases for testing the efficacy of any new remedy.

CASE I.

Mrs. Biggs' child, aged 2 years, visited September 21st, and found labouring under diarrhœa, with tenesmus, vomiting, quick and feeble pulse, furred tongue, thirst, hot skin, and great irritability, dejections slimy and very offensive. These symptoms continued unabated for the four following days, resisting entirely the usual treatment, which consisted of mild mercurials, with Dover's powder, together with absorbent and alkaline medicines, with occasional doses of Ol. Ricini and Tinct. Opii.

On the 26th, the tenesmus being very depressing, and the motions frequent and very fœtid, the following embrocation was rubbed freely over the abdomen and dorsal region:—R. Chloroform., m. viij.; Ol. Terebinth., dr. ij.; Lin. Saponis., dr. vj. Misce.

27th. Tenesmus relieved, but the diarrhœa unchecked; extreme emaciation, and the case apparently hopeless.

27th. Continue the embrocation, and give the following mixture:—R. Chloroform., m. vi.; Mucil. Acac., dr. iv.; Tinct. Opii, m. vi.; Aquæ destillatæ, ad oz. j. Fiat mistura. A teaspoonful to be given every two hours.

28th. A marked improvement in all the symptoms; the infant has had but one dejection during the night; slept soundly; motion this morning improved in colour and consistence; pain and irritability much relieved. Ordered a little wine and arrowroot, and to continue the chloroform mixture at intervals of four hours.

The child has suffered no relapse, and is now, the 30th, free from other ailment than that arising from the debility consequent upon the attack.

CASE II.

Mrs. Stanton's infant, aged fifteen months, was similarly attacked on the 23rd of September, and prior to the administration of the chloroform on the 28th, a similar mode of treatment was adopted as in the former case, with the exception that the opium in this case was pushed, in the form of Dover's powder, to a further extent. The symptoms, though not accompanied by so much tenesmus, were equally obstinate, and the emaciation excessive; the stools being pink and watery. On the 28th the same chloroform mixture was administered, and the embrocation used, and with the same happy effect. The gradual recovery of the infant may be dated from the exhibition of the first dose of the chloroform, and during recovery she required no other treatment, save an occasional dose of calomel.

A case of dysentery occurred at about the same period, though prior to those above related, which resisted every mode of treatment, the child sinking about the tenth day.

On the 20th of September, another case of dysentery occurred, in a boy aged about 8 years, which promised to run an equally severe course with the former one. The

child suffered severely from pain and tenesmus, accompanied by frequent bloody stools, the dejections resembling currant jelly, with water, accompanied with much fever; and having resisted leeching, blistering, castor-oil aperients, with opiates and astringents, until the 26th of September, the following mixture was ordered:—R. Fel. Bovis Inspiss., gr. xij.; Tinct. Opii, m. x.; Mucil. Acaciæ, oz. j.; Chloroform., m. vi.; Misturæ Amygdal., ad oz. iij. Fiat mistura; capt. sextam partem quartis horis. Under this treatment, with occasional doses of Dover's powder, this child speedily recovered, and is now, October 7th, convalescent.

I am, Sir,
Your obliged servant,
THOMAS HEWLETT.

TRAUMATIC FISTULA OF STENO'S DUCT: CURE COMPLETED DURING A CONTINUED FEVER.

By Tuthill Massy, M.D., Exeter.

The patient was by occupation a mason, 43 years of age. When he presented himself to me, in September, 1847, he stated that he had fallen off a scaffold, six feet raised from the ground. He had a lacerated wound, extending from below the centre of the right malar bone to more than an inch. The eye and nose on that side were greatly swollen. The wound was brought together with strips of adhesive plaster. Ordered an aperient, with directions to live low.

On the third day, when eating bread, he felt water pouring down his cheek; his neck and skirt were quite wet.

I removed the dressing on the fifth day, and got him to chew a bit of bread, when the fluid *poured out*; it then formed a little stream trickling down the cheek.

On the seventh day the wound was united almost throughout the entire extent, leaving two small openings at each extremity, sufficient to admit the point of Anel's probe, and through which flowed, (as the man stated,) "a wine-glass of water during each meal." Touched the openings with a pencil of Nitras Argenti. Applied a lint compress.

Tenth day. He was attacked with the fever which was then endemic in the adjacent lodging-houses. Complained of a heavy pain in the head, with loss of sleep and appetite; tongue dry, and coated with a white fur; respiration hurried; pulse quickened.

Eleventh day. Great thirst; the saliva has ceased to flow.

Thirteenth day. Fever continues; urine diminished in quantity.

Fifteenth day. Fistulous openings closed; a hard oval tumour occupies the entire extent of the cicatrix, not in the least diminished by pressure.

Twentieth day. The tumour continues tense, and unyielding to continued pressure; fever almost gone; appetite returning.

5th of October, being thirty days. My patient is convalescent. The tumour has disappeared; the cheek is natural; and the saliva escapes through its own opening into the mouth.

How has this duct become a continuous tube? Has lymph united the parts by forming a sac between the divided extremities?—or have the walls of the tumour formed the connecting link?

CASES OF POISONING BY BELADONNA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

I forward you two cases of poisoning by belladonna, occurring lately in my own practice, which are interesting as bearing upon the late inquest at Sheffield, where the verdict of the jury appears to me to have been the opposite of that to which a careful review of the evidence would legitimately lead.

Your obedient servant.
SAMUEL COWAN.

Bath, Oct. 5, 1848.

Case I.

June 25, 1848. General W., aged 73, a man of hale robust constitution, swallowed in mistake for a henbane draught, part of a lotion, containing, as I afterwards calculated about twenty five grains of the extract of belladonna dissolved in Linamentum Saponis.

I was sent for, and saw him at 11 p.m., about twenty minutes after the accident, mustard and water having been previously administered to excite vomiting, without effect. I found him perfectly collected, complaining of slight vertigo, with staggering gait; the surface and extremities cold; the face pale; indistinct articulation; pulse feeble, 74; pupils *not* dilated. The stomach-pump was used, and the stomach freely washed out, the fluid returned containing a greenish mucus, convincing me by its smell that the poison was belladonna. Small quantities of brandy and water were now given. Vertigo and insensibility gradually increased; the temperature of the skin and extremities sank; the pulse became weaker, and fell to 55. The pupils were now fixed, scarcely at all dilated, and he sank at twelve p.m. into a state of profound coma, from which it was impossible to rouse him. The dysphagia which had more or less shown itself since the commencement, increased to such an extent that it was impossible even to give him a teaspoonful of fluid without threatening suffocation. Mustard cataplasms were applied to the trunk and extremities.

12 p.m. The pulse gradually rose to 130, and became hard and bounding in character; the vessels of the head were congested; face flushed; sclerotics injected; pupils fixed, very little dilated; breathing stertorous and laboured; extremities cold, in fact all the symptoms of a well-marked case of apoplexy. I now opened the temporal artery and bled him to fourteen ounces; the pulse very shortly fell to 60, became softer, more compressible; face became paler; and the temperature of the trunk and extremities returned. The stupor was still profound, with stertorous breathing, pupils fixed, dysphagia extreme. A large turpentine enema was thrown up the bowel.

At 2 a.m., the left side of the face was much convulsed; the left arm and leg cold and apparently paralysed; convulsive movements of the right side; the coma and stertorous breathing remaining; pulse

fuller, 70. Between this time and five a.m., the power of deglutition gradually returned, when he could be roused by a sudden noise, though not sensible.

6 a.m. A low muttering delirium now came on, with violent spasmodic movements of the right side. The temperature of the left side gradually returning.

7 a.m. Insensibility continues; stertor is gone; pupils a little contractile to the light of a candle; could be roused by a loud sudden noise, but could not articulate.

From this time till 12 at noon, when the catheter was passed, and a large quantity of water drawn off, consciousness had partially returned, the delirium alternating with it; complains of double vision; pupils contractile; deglutition perfect; pulse soft, 84. The turpentine enema which had been retained all night, now passed. Nourishment was given him, and a calomel pill and draught.

27th. Has passed a good night; consciousness quite returned; no double vision; complains of debility, and there is partial paralysis of the right arm and leg. Has no remembrance whatever of any circumstance since the use of the stomach-pump.

Under the use of ammonia and camphor he gradually regained his strength.

CASE II.

Mrs. H., aged 34, of a spare nervous habit, was ordered a four-ounce lotion, containing one drachm of the extract of belladonna, for painful condition of the breasts twelve days after confinement. A fourth of this was by mistake given her, instead of a henbane mixture. Owing to distance she was not seen for nearly an hour, nothing having been done in the meantime.

April 3rd. At ten p.m., I found her in the following state:—Surface cold, clammy; face pale, distorted; mouth drawn to one side; pupils fixed, and immensely distended; complete insensibility; breathing stertorous, hard, regular, slow; pulse 50, very compressible, irregular; extremities cold; hands clenched. Ordered a turpentine injection, (two ounces,) and small doses of ammonia, with mustard cataplasms to the stomach and extremities. The dysphagia so great, and suffocation so imminent, that neither the stomach-pump could be used, nor stimulants swallowed.

11 p.m. Cold affusion to spine.

12 p.m. Reaction beginning; the same symptoms continue, with the face flushed; sclerotics injected; vessels round the head turgid; breathing quicker; pulse steadily rising, harder, 130; surface and extremities cold; dysphagia extreme. Twenty-four leeches to the temples. Ice to the head.

2 a.m. Face paler; pulse softer, 100, regular; surface and extremities warmer; insensibility continues; stertorous breathing; pupils fixed, not so dilated; dysphagia less; spasmodic movements of the limbs; twitchings of face.

3 a.m. Low muttering delirium came on, and increased till five o'clock, when there was the wildest delirium, accompanied with violent muscular efforts; pupils less dilated; face flushed; dysphagia less. Twelve more leeches. Ice.

5 a.m. Delirium not so violent; wanting to get out of bed; living in dreams of the past.

8 a.m. Can swallow a little; pulse softer; face less flushed; delirium less violent, low muttering; can be roused by a sudden noise; urine drawn off by a catheter.

12, noon. Delirium passing away; corrects her false impressions; pulse softer, 80; pupils contracted; diplopia; wants food; complains of weakness; left arm and leg paralysed. She continued through the day partially delirious.

April 5th. Appears quite recovered, though excessively prostrated. Complains of great loss of memory, having no recollection of the last two days. In about a week all unfavourable symptoms disappeared, and she gradually regained her memory and bodily strength under the use of ammonia, with tonics.

REMARKS.—Both these cases presented the well-marked general symptoms of poisoning by belladonna, though we find in each a variation in special symptoms worthy of notice, when considered in reference to the verdict given at Sheffield, at the inquest of Thomas Greaves, and the evidence of Mr. Law, as reported in the Journal of September 20th. Upon a careful review of the evidence adduced in that case, I doubt the correctness of the verdict given, and fully believe with Mr. Jackson, that death arose from the poisonous influence of belladonna on a system previously debilitated by age and disease.

In a healthy man, though aged, the quantity said to be taken would probably be ultimately harmless; but when we find, as in this instance, a man 76 years of age, labouring under gastric symptoms, (as I judge from the plaster ordered to be applied to the stomach,) and a chronic inflammatory condition of the bronchial membrane, the swallowing of five grains at least, *and probably more*, of the extract of belladonna at six o'clock in the evening, and soon after the complaining of tremor, debility, coldness, loss of speech, dilatation of pupils, dyspnœa, followed in a little time by general reaction, swelling and congestion of the face and head, with dryness of the throat and fauces,—in short, all the symptoms of congestive apoplexy, and the patient left in this condition without medical aid until nine o'clock the next morning, we can come, I think, to no other rational conclusion, than that death resulted proximately from the action of belladonna on an enfeebled and diseased body, and directly from the consequent effusion into the ventricles of the brain and spinal canal.

I believe, in the two cases reported above, that death would probably have occurred from cerebral effusion, had the brain been left as long (fifteen hours,) unrelieved by local bleeding; and cannot but think that, had Greaves received medical aid at the proper time, he would have recovered. The absence of a single symptom, such as insensibility of the pupil, as noticed by Mr. Law, cannot be looked upon as important, as pathognomonic of poisoning by belladonna, for we find in Case 1, above, the very symptom (dilatation of pupils,) of all others considered characteristic of the influence of belladonna, *absent*.

It is difficult to arrive at the dose of the drug that will destroy life, but I believe that the patient's well-being hangs upon timely relief to the cerebral vessels in the period of reaction, and that, if this relief be withheld, the patient will sink under the cerebral effusion induced.

I have not the least doubt that the case of Thomas Greaves was one of cerebral congestion, arising from the influence of belladonna, and that, from want of medical aid, serous effusion took place into the ventricles and spinal canal, and thus destroyed life.

SPASM OF THE GLOTTIS.

An Answer to Dr. Ogier Ward's last Letter.

"——— In all such cases a man may fill a couple of pages with suppositions—which of these was the cause, let the curious physiologist or curious anybody-else determine—'tis certain at least Trim went on———"

Tristram Shandy.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

It is not without some degree of reluctance that I again trespass on your columns, as I am sure your numerous readers will by this time be tired of a question respecting which, from what has already been said, the majority must have decided with themselves as to the truth and correctness of the point calling forth this discussion; yet, as Dr. Ward fancies I have misrepresented him, and as it is quite evident that this gentlemen has wittingly passed over certain facts and considerations that are hostile to his views, and which go to prove the fallacy of his notions regarding the real nature of this affection, I at once determined to reply, and should have done so sooner, had not circumstances protracted this delay. I repeat the observation made before, that it is of importance that a right view be taken of the pathology of this disease—that its real causation be enquired into, because upon such we base our treatment, and the *kind* of treatment in some instances would most assuredly involve the results of life or death. It is a formidable affection, in one of the most important organs of the body, and notwithstanding its being not of every-day occurrence, it certainly merits the attention of the practical physician. I am pretty well satisfied in my own mind, that occasionally, when people die in fits, and the cause is attributed to other conditions, a spasmodic closure of the glottis is the real cause, and one that should call forth our attention in remedial measures. It is a fact, though, perhaps, not very generally admitted, that the engorgement of the vital organs is not unfrequently as much, or probably more, a result than a cause of symptoms that either lead to, or threaten, a fatal issue, in the kind of affections now particularly spoken of,—viz., fits. Irritation in one or other of the nervous systems, may give rise to vascular turgescence at the base of the brain, as from irritation in the lining membrane of the alimentary canal,—in the uterus, or in children, during dentition; and this turgescence, producing *pressure*, is followed by spasmodic action in the larynx, the closure of which organ is necessarily followed by pulmonary obstruction, an over-loaded condition of the heart, and lastly, encephalic congestion—phenomena, whose effects add to the first cause. Hence under such physiological and pathogogical reasoning, in these cases, the kind of treatment, and the part to which the remedies are addressed, must from such review of the disease be importantly varied. Philosophical experimenters and practical men, have recently confirmed the correctness of such way of thinking; and those improvements which are to render more certain the employment of our art, must spring not only from the watchful observance of external phenomena, but by digging deep into causation,—by referring to sympathies and distant connections between organs,—by tracing cause down from effect, and attacking the former instead of the latter. Had my opponent in opinion, been more impressed with these considerations, his attention would not have been chained to one particular part, and *its* appearances and conditions, but his attention and ratiocination would have extended to the cerebro-spinal system, instead of merely to the nervous branches given off from that system; he would, I repeat, have reasoned more respecting causes than effects.

Last evening, at a late hour, I was summoned to see a young lady, who had suddenly, to all appearance, become alarmingly ill. There was hysterical sobbing and irregular convulsive breathing, also powerful chirismus. Antispasmodics and rubefacients to the spine were soon followed by relief. Now, instead of this powerful chirismus, there might have been laryngismus—why not the one as likely as the other, although the importance of effects and probable results would have been immensly different? Who would for a moment have thought of addressing his remedies to the cramped hands, and have omitted the far more weighty considerations of the spinal marrow, yet laryngismus and chirismus, or podismus are produced by the operation of similar far off causes.

In thus returning to the question of this letter, it should be remembered, that I never denied that in cases of spasma glottidis there might be redness preceding, or indeed a degree of sub-acute laryngitis, and on reference to my first article, the following passage will be found:—"There are good reasons for believing that inflammation by its irritative properties, produces spasmodic closure of the fissure, and thus the sudden termination in death may at once be accounted for;" after which an illustration is given of a man who thus died in the wards of the Edinburgh Royal Infirmary. I have also affirmed that, in the adult, its spasmodic closure without any preceding redness, or inflammatory affection, does at times occur, and this I maintain. It is very likely that redness or increased vascularity would be a result in most instances; and surely Dr. Ward knows that a spasmodic, will often terminate in an inflammatory affection. Spasmodic twitchings in the bowels occasionally give rise to, or at least are, the first symptoms of some description of abdominal inflammation. Persistent spasm of the urethra is followed by tumefaction, and all the veritable characteristics of the inflammatory state.* Dr. Ward, in the commencement of his letter, merely makes a denial, relative to the female there alluded to being hysterical, yet gives neither negative nor positive reasons in substantiation of this assertion. Why, every man of experience knows how great the natural proclivity is, in young females, to the development of anormal and irregular actions of the nervous system, and when a young person like the patient is suddenly

* Art. "Symptomatology," Cyclop. Pract. Med. by Dr. Marshall Hall.

taken with choking, as Dr. Ward describes, it would be difficult to say with positiveness that she was not an hysterical subject. The great mobility which there is in the nervous system of women, constantly renders our diagnosis wavering and uncertain; and when you see sudden, instantaneous, spasmodic affections, to stoutly assert that these are unassociated with that morbid condition of the nervous centres, known by the generic term hysteria, would often be assuming a position on doubtful grounds.

Dr. Ward informs us the patient had influenza, a disease acknowledged by pathologists, as first exerting a depressing effect on the nervous system generally, and succeeded by pulmonic disorder, but not as Dr. Ward infers, associated with acute laryngitis. Dr. Smith's cases were instances of idiopathic laryngitis, not connected with influenza, nor is any mention made by Dr. Smith in his statement to me, relative to his cases, and which I inserted in my last letter to Dr. Ward, touching this question. Dr. Ward may, it is true, have *inferred*, they were associated with influenza, but such inference was certainly erroneous. When Dr. Ward examined the throat of his patient why did he not detect the redness,—a symptom upon which his views are entirely based. I reiterate, then, I *do object*, because as I have said, the spasmodic closure was in a young female, it declined with as great celerity as it supervened, where influenza could not account for it, and much more, when no inflammatory traces were observable in the throat.

As Dr. Ward goes on, he would appear to infer there was inflammation of the trachea, because Dr. Browning Smith happened to have two or three cases of acute laryngitis about the same time. Now, there is not a more formidable disease than acute laryngitis, and it is exceedingly improbable that Dr. Ward's case was one of acute laryngitis, because there was a very sudden remisssion of the symptoms,—because if it had been so there would have been discernible undoubted vascularity, and because no one before Dr. Ward and M. Bretonneau ever heard of powdered alum, instanter dispersing acute inflammation.

In Mr. Alford's case, the redness was observed *after* the attack, and when there has been violent spasmodic twitching amongst the vascular and soft parts, as about the larynx, it would be succeeded by vascular obstruction—by a condition of redness. Surely redness—mere vascular turgesence, might result so soon, if we were to credit Dr. Ward's notion of momentary tumefaction and its momentary declension.

Dr. Ward makes an essay to get out of this on the score of philanthropy, by desiring not to give the patient unnecessary pain, by properly examining. If the redness had been there, it might easily have been detected. As regards my own practice, I always hold it a rule to fully satisfy myself as to the real nature of a disease, even at the expense of giving the patient a little pain; however, I do not say anything otherwise than admire Dr. Ward's finer feelings.

The writer then goes on about the alum story again, and endeavours to give weight to that novel treatment by "pinning to his faith" the name of M. Bretonneau, who is mentioned as deserving the credit of the discovery, and that *he* (Dr. Ward,) borrowed the idea from M. Bretonneau. I am afraid Dr. Ward would here remind me of my "want of reverence for great names." I will, however, by and by, show that I no longer stand under this imputation, and shall cite one or two eminent authorities.

Next comes Dr. Ward's astonishment that I should ever dream (in an instance that I conceived one of imminent danger,) of putting my finger down a patient's throat! Was it on account of its inelegance, or of the too great heroism in this expedient that the digital rotation was complained of? If called at the moment of writing this, to a patient suffering in the manner described, I should certainly not for an instant hesitate to have recourse to the same, (not regarding the rank, sex, or caprice of my patient)—yes! to putting my finger down a delicate lady's throat. What! in emergencies like these, are we to render our treatment imbecile by erroneously conceived punctilious observances?—would any prefer elegance to agony?—are we to stand, and study, and contrive, how neatly and nicely we can perform such a trifling operation?—allow danger, and pain, and distress, to continue as if intense human suffering were of less consideration than the seemly means by which relief could be ministered? In such eventful emergencies, not a moment is to be lost. Who would delay or vacillate?—and, strange it would appear, to procrastinate in the performance of our duty in order to notice trite rules of ceremony, and the niceties of etiquette. Perhaps Dr. Ward would have preferred the more graceful titillation of a feather! If there had been considerable inflammation in the throat, I should certainly, if possible, avoid this method. I recommend its adoption in cases of laryngismus, not laryngitis. I did rotate my finger in the cases I have given, which is mentioned in the report of the girl Cooper, though omitted in the young man John P.

Dr. Ward next begs to remind me that the treatment is not original, and even thinks that I copied such from Mr. Alford, or some other, as Dr. Ward now admits his borrowing from M. Bretonneau, the alum theory. I recollected that I saw some account in my readings of putting the finger down the throat years ago. I was summoned in emergency, and on the instant put the recommendations into practice. Dr. Ward may perhaps think there is too much of the *fortiter in re* in such a measure on the part of the medical attendant; but a patient writhing under the impending pangs of threatened suffocation, would prefer being relieved *fortiter in re* to the inefficient *suaviter in modo*.

"*I do not know why Dr. Wardell should suppose that I needed his instructions respecting the effects of vomiting in removing obstructions in the larynx.*" I would here ask Dr. Ward, did he definitely wish it to be understood that he gave antimony to produce muscular relaxation, or with a view to its antiphlogistic properties? The writer then points out the very important fact, that I mis-quotod him by saying *nineteen*, instead of nine, grains of alum. Proceeding in the letter, an effort is made to support the theory of instantaneous

inflammatory swelling, by citing the phenomena of erysipelas, black-eye, &c., none of which sufficiently bear upon the question.

"*I would beg to refer Dr. Wardell to Dr. Smith's third and fatal case of laryngitis, in which this (tumefaction of the glottideal coverings,) morbid state occurred when it did not appear to have been suspected.*" I cannot conceive why Dr. Ward thus states it was not suspected, when there was effusion of pus, and a distinct false membrane formed;—in fact, when the intensity of inflammation in the larynx was so considerable as to cause death, how could it be conceived otherwise, than that the rima should be swelled and inflamed, and that particular proneness of the soft parts here to tumefy, and which Dr. Ward has so repeatedly told us of. Surely such could not be matter of surprise. Though apparently mentioned in an incidental manner by Dr. Smith, in his account of the morbid appearances, it was thus referred to as a matter of course. This is, indeed, begging the question. The merest tyro in pathological anatomy would have looked for œdema of the rima, when the surrounding inflammation was such as to induce a fatal result.

"*Dr. Wardell refers to the Cyclopædia of Practical Medicine*, "*Laycock, on the Diseases of Women*," *&c.* The writer of the article in the former, says,—"It occurs chiefly in children, though in some rare instances *it has been observed in adults*, chiefly in nervous old women and young persons." Dr. Joy's opinion then cannot certainly be cited *against* the doctrine which I have endeavoured to uphold. Dr. Ward again quotes from the article in question as follows:—"Fatal spasm of the glottis in adults takes place occasionally from irritating causes in the neighbourhood of the larynx, &c." Exactly: and if Dr. Ward will refer to my first paper, published a year ago, he will find the same statements there expressed, with the mention of Dr. John Reid's experiments. That gentleman has abundantly proved that irritation in the recurrent laryngeals will close the glottideal fissure; but Dr. Ward must not content himself with the inference that irritation is alone produced by inflammation; tumours or pressure, from any cause, upon those branches, will give rise to spasm, and in every case of spasma glottidis, it is irritation from pressure or otherwise, that produces the phenomena.

Dr. Ward has certainly omitted notice of the radical causes—says nothing of the brain possibly being the seat of the disease, but with pertinacity clings to the glottis, where the *effects* are located. In such instances as are noticed in adults, where no inflammation exists, we must, if a scientific view be taken of such cases, refer the causation to the operation of morbid influences on some part or parts of the nervous system; not because anomalous affections, and ill-understood or guessed-at diseases are conveniently referred to that ambiguous system, but because philosophical experimenters and practical physicians have incontestably shown that irritation at a distant part *will* close the glottis. Laryngismus is a secondary, not a primary, affection, produced precisely by like morbid causes as those influencing the muscles of the eye, and which he terms strabismus. The German pathologists are unanimous in their opinion that the disease is of cerebro-spinal origin. Andral and Velpeau recommend it to be treated by antispasmodics, and Dr. Clark thus delivers himself:—"I have no doubt the brain is the seat of the disease." Dr. Marshall Hall states that, "in a girl, 13 years of age, croup-like convulsions occurred repeatedly, until one day, when the bones of the cranium separated, which put a final period to them." In another case cited by that eminent authority, "croup-like convulsions occurred whenever the child affected with spina-bifida was turned, so as to press upon the tumour."* Dr. Hope says,—"All, whether chronic, as in convulsions, or tonic, as in rigid contraction, is assumed to depend upon the excito-motory system." In a paper, by Dr. Marshall Hall, in the *Lancet*, June 12th, 1847, when speaking of the convulsive affections of infants, the author thus expresses himself:—"It would be unphilosophical and unreasonable to think, and speak and treat, of the condition of the larynx separately, and to view the case (laryngismus,) as one of partial paralysis or of *inflammatory action*, as so to view the affection of the muscles of the eye-ball, the fingers, or the toes, which differs in no respect from that spasmodic affection of the larynx, except in their less formidable import." To again cite from Dr. Hall:—"Laryngismus, so far from being peculiar as an affection in infants, is, as I have already stated, common to a whole class of affections of the true spinal system, emotion, hysteria, epilepsy, tetanus, hydrophobia, one and all affect the larynx especially,—one and all produce a state of varied laryngismus. This affection of the larynx, therefore, instead of being a disease, or a symptom of a disease, is a symptom denoting an affection of a certain nervous system." In puerperal convulsions, the livid congestion of the features, and all those frightful symptoms associated with that disease, are dependent upon glottideal spasm, being produced by pressure at the base of the brain;† hence the necessary remedy of blood-letting, to relieve the cephalic congestion. So long as the source of irritation remains, will the affection be liable to return in its paroxysmal attacks, which are so characteristic of nervous diseases.

Very recently I was requested to see an elderly gentlemen, who was reported to be suffering under violent convulsive twitchings, which were so painful as to make him cry out in the intense pain which he suffered. This gentleman, whose name ranks high in the military services of his country, had, during his professional career, been much exposed to the fatigue and hardships of active service, and especially to variations of climate. Some years ago paraplegia supervened, on a constitution already impaired, and since the accession of that disease, whenever the digestive apparatus became disordered, convulsive twitchings of the limbs or severe asthma came on. When I saw him, every five minutes the convulsive twitchings of the voluntary muscles returned. He was treated according to general principles, but it was not until the alimentary canal

* "Libr. Pract. Med.," vol. viii, p. 51.

† See my paper "On Puerperal Convulsions," being Case No. 3 of the series.

was efficiently unloaded that the affection ceased. The stools were at first most vitiated. Here, then, was an example where the great nervous centres were diseased, and where irritation applied to one part gave rise to convulsive actions in another. Why might he not have had laryngismus instead,—and was not one set of muscles as liable to be thus reflectedly acted upon as another?

It is indisputably evident, both from what we observe in the phenomena of disease, from a rational theory deducible from physiological experiment, as also from pathological appearances, that the glottideal fissure may be, and at times is, closed from other conditions than inflammatory irritation. M. Vunthier says, "in spasm of the glottis the voice is natural; there are no laryngo-tracheal hissing, no fever, and no false membranes; the fit consists in convulsive respirations, and lasts at most for a few minutes."

Dr. Ward cites from Dr. Laycock's book, and writes as follows:—"*Dr. Laycock mentions a case in the York Hospital of a patient whom he found in a comatose state, from a sudden attack of hysteria, combined with epilepsy, which had induced asphyxia, and which he succeeded in relieving by introducing his finger into the throat, and his observation is 'in this patient hysteria had passed into epileptic paroxysms, and it is in such cases that we have laryngismus stridulus.'*" Dr. Ward then winds up this paragraph as if, exultingly, under the impression that such citation is a poser, and says,—"*Are these, then, the authors on whom Dr. Wardell relies for accounts of pure uncomplicated spasm of the glottis in the adult?*" For Dr. Ward's argument, no quotation could have been more out of place and infelicitous, as he is thus, in some measure, substantiating the doctrine I have maintained. From first to last I have particularly insisted upon its frequent occurrence in hysterical females, and yet, forsooth, Dr. Ward gives an hysterical case, where pure spasma glottidis did occur, as if in controversion of my doctrines. Where Dr. Ward errs, is by dwelling upon effects instead of causes. What is hysteria? A name given to a morbid excitability in the nervous system of some females, and intimately associated with the generative and uterine organs. This may be given as a definition. But to more specifically or more accurately define one of the most protean of maladies, would indeed be difficult. Epilepsy, so called, is a kindred affection, and every practical man must be aware that cases are at times presented where hysteria and epilepsy, so called, are inextricably blended. To draw the line of demarcation is often impossible, and the conclusion arrived at would be at best but an arbitrary distinction.

Where I have used the word *pure* and *uncomplicated* spasma glottidis, those expressions were, of course, synonymous with the term non-inflammatory. The question between Dr. Ward and myself is, I reiterate, whether inflammation in the throat always is the cause of laryngismus. I might here repeat what has already been said above, as to the ultimate causes of the affection. Those grave symptoms in epilepsy, such as congestion of the features, congested lungs, &c., are results of the spasm of the organ in question, the spasm is not caused by these. I would particularly refer Dr. Ward to the works of Dr. Marshall Hall and to Dr. John Reid's experiments on the 8th pair,—authors whom Dr. Ward in his researches must have forgotten.

The "Library of Practical Medicine," vol. 3, is now laid open before me, and I read the head "Nervous Affections of the Larynx in the Adult," a title rendering it pretty evident that the writer, (Dr. C. J. B. Williams,) is about to describe the affection now under discussion. In the first section the author says, that "*spasmodic affections of the larynx in the adult occasionally occur as the result of more distant spinal or nervous irritation.*" Again he says, "*like the crowing inspiration of infants, this may arise from temporary irritation, or from more permanent disease of the nervous centres. Dr. Stokes mentions cases in which spasmodic affections of the larynx terminated in inflammation of, and effusion under, the membranes of the brain.*" To cite this gentleman once more, as Dr. Ward has particularly directed my attention to the "Library of Practical Medicine. "*The treatment of spasmodic affections of the larynx is to be generally conducted on the usual principle, of giving antispasmodics to remove or prevent the attacks, and improving the tone of the muscular system, and diminishing nervous irritability, by tonics, regular exercise in the open air, and other suitable means.*" This is certainly not the happiest reference made by Dr. Ward to eminent authorities. Dr. Ward makes an effort to get out of the testimony supplied by the article referred to, by not receiving the statements as implicit, because the author did not encumber his article by the production of cases, whereby he (Dr. Ward,) might have more correctly judged. If any of your readers will take the trouble of opening the 3rd Volume of the "Library of Practical Medicine," Dr. Williams' description and meaning cannot for a moment be misunderstood. Not long ago Dr. Williams and I had some conversation respecting the question now agitated; and I put this question to that gentleman. "Have you, Dr. Williams, in your practice, ever seen cases of pure, non-inflammatory, spasm of the glottis in the adult?" "I have, without any doubt, in four or five instances," was the reply. Dr. Walshe thought it highly probable such cases might occur, but he could not then call to recollection an apt illustration. I mentioned to these gentlemen the alum story, as given by Dr. Ward, also when writing to Dr. Henderson, of Edinburgh, but none of them could be convinced of its instantaneous and novel properties.

"*I confess Dr. Smith's case of the "lad" made me think I might have been too hasty in my denial of the existence of the disease in the adult.*" Dr. Ward's conviction is shaken. He goes down to Brompton, ferrets out the lad at Earl's Court, subjects him to cross-examination, and after divers interrogations, the patient says "yes" to "dryness and pricking," and then Dr. Ward comes home quite satisfied that it *must* have been inflammatory. Now, after the elapse of many months, would it not be quite probable that the patient would speak of "pricking and dryness," or almost any symptom, desired to be elicited; or if Dr. Ward mentions another attack, as he speaks of, the "11th ult.," still some weeks had elapsed from the occurrence

of the affection and the date of Dr. Wards letter, and it is scarcely to be supposed that such after-recollected symptoms could be admissible in evidence here. But I refer to the time Dr. Smith attended the patient, when the choking came on in an instant, and when the paroxysm as suddenly vanished, and when the case was treated with, and cured by, antispasmodics, by stimulants, by brandy-and-water; and here again I emphatically deny, on the *ipse dixit* of Dr. Smith, that there was any *inflammatory* affection whatever.

In conclusion, then, it must be admitted by the impartial reader, that Dr. Ward has unquestionably failed to maintain his point, or set aside the doctrine which I gave in the first articles touching this question. The girl Cooper, and the young man John P., as also Dr. Smith's illustration, are abundantly sufficient in confirming my own argument, and I trust when Dr. Ward takes a more philosophic and comprehensive view of the question, he will not dwell so much upon *effects* as causes, and that he will see that irritation, transmitted or originating in the laryngeal nerves, is not always the result of positive inflammation in that organ, and consequently, instead of an antiphlogistic, (as his theory would ever presuppose,) an antispasmodic and tonic mode of treatment is indicated. "We agree with Dr. Wardell," says the Editor of Ranking's "Abstract of the Medical Sciences," in the last volume, "that his cases were instances of spasm of the glottis in the adult, which are far from being as uncommon as represented. *We have seen three or four instances* at least of this affection, as a symptom of reflected uterine irritation. We have treated the paroxysm in the adult as in the child, by dashing cold water on the face, emetics, &c. Had they been cases of acute laryngitis, as supposed by Dr. Ogier Ward, the pulse would not have remained under 100, nor would the remissions have been so distinct."*

I am, Sir,
Your obedient servant,
JOHN RICHARD WARDELL.

CAUSE OF MORTALITY IN DIFFICULT LABOURS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I agree with you that, as Professor Simpson's calculations and mine are now before the profession, we may leave them to form their own conclusions. I wish, however, to correct some *important errors* of statement as to *facts*, in his letter to me in the last number of your Journal. He asserts that *I maintain* that the mere protraction of labour is not a material cause of danger to the mother. I never made any such statement: my statements have invariably been made to prove that the mortality from protracted labour was strikingly small, and that the great mortality is from other causes.

Professor Simpson also asks, why I did not state, that during the first three years of my Mastership, out of 5,629 women delivered, 106 died, or one in 53? I answer, I could not state so and state a fact, as there were 7,547 deliveries in the period stated, and 110 deaths, including 59 from puerperal fever, or one in 68. Professor Simpson states I was Assistant Physician in the Hospital in 1826. This is also contrary to the fact. I was appointed Master in November that year, and my calculations are all given from that period.

Professor Simpson asks why I did not report the mortality during five years I had nothing whatever to do with the hospital?

Professor Simpson states, in reply to my remark upon the excessive mortality of one in 21 in the Edinburgh Hospital, under the late Professor Hamilton. "You know that this high mortality arose from the prevalence of puerperal fever." I beg to say that Dr. Hamilton peremptorily declares that *not one case* of puerperal fever occurred in the above period. (See the late Dr. Mackintosh's Essay, published in 1823, where he asserts the mortality was one in 18.)

Professor Simpson states that he thinks he sent a report of the Edinburgh Hospital, which I never even heard of. He also states that I choose to criticize him for losing in his private practice, two mothers from puerperal fever, when using anæsthetics. I made no observation of the kind: I stated that he lost *four* patients out of 170, or in the large proportion of one in 42.

In conclusion, I beg leave to state, that I have no observation to make upon Professor Simpson's *novel* calculations of the *comparative average mortality* between patients where there is no difficulty whatever in the labour, and those that are accompanied by the most extreme difficulty and danger.

I am, Sir, Your obedient servant,
ROBERT COLLINS, M.D.,
President of the King and Queen's
College of Physicians in Ireland.

Merrion Square, Dublin,
Nov. 6, 1848.

* Vol. vii., p. 38.

PROVINCIAL
Medical & Surgical Journal.

WEDNESDAY, NOVEMBER 15, 1848.

It is gratifying to have to state, that at this period, when the cholera has actually made its so long anticipated invasion, the state of the public health is in a more satisfactory condition than it had been for some time previously. From the Quarterly Return of the Registrar-General recently issued, we learn that the mortality of the last quarter is considerably below the average, and that a marked improvement has very generally taken place in the public health throughout the country.

"The mortality of the country," says the

report, "it should be recollected, was low in the three years 1843, 1844, 1845, and in the first quarter of 1846; a slight increase took place in the spring quarter of 1846; in the summer a great mortality broke out, and continued through the autumn, as well as the whole of the year 1847, until influenza raged epidemically at the close of the year 1847, and was then, and in the winter of 1848, fatal to thousands. A remarkable improvement was apparent in the spring of the year 1848, and was still more obvious in the summer quarter. While the deaths in the summers of 1846, 1847, were 8660 and 5986 above, the deaths in the summer of 1848 were 809 below, the corrected average." The mortality of the quarter just ended is less by 6034 than in the corresponding quarter of 1847, and 7960 less than that of the preceding year.

On referring to the reports of some of the local Registrars, we find that the improvement in the health is attributed to an improvement in the circumstances of the population; thus the Registrar of St. Ann, Nottingham, attributes the improvement, among other causes, "to the comparative cheapness of provisions; the Registrar of Middleton, Oldham, ascribes it "to the exceedingly low price of provisions, &c."

We were curious to ascertain how far the mortality from bowel complaints, during this period, might indicate a tendency to the approach of the prevailing epidemic.

On referring to the observations of the report on this subject, we find frequent mention of diarrhœa, cholera, and dysentery. Thus diarrhœa prevailed at Brighton, and was fatal to young children. The mortality in Ipswich and Yarmouth had fallen nearly to the average; diarrhœa was, however, fatal to children in those towns. Dysentery caused sixty-five deaths in Penzance, and was also fatally prevalent in Marazion, ascribed by the Registrar of that district to the poverty of the population, the dampness of the season, and impoverished diet. A few cases of common cholera proved fatal in the Lancasbire districts. Of the deaths in Hull, amounting to 213, thirty-nine were from diarrhœa, and four from cholera. It may be observed here, that in Sunderland, Gateshead, Tynemouth, and Newcastle-on-Tyne, the mortality was very nearly the average of the year preceding 1846.

Two instructive tables are given of the deaths from diarrhœa and the deaths from cholera, in each of the four quarters of the years, from 1840 to 1848. It is, perhaps, unnecessary to state, that the cases are greatly more frequent in the quarter July—September. In the case of diarrhœa, a marked increase is shown in the mortality from this affection in the last three years, although that of the quarter just finished is one-third less than that of the corresponding quarter of the year 1846.

The following table is drawn up from the tables given in the Report:—

Table of Deaths from Diarrhœa and Cholera during the Quarter ending September 30th.

	Diarrhœa.	Cholera.	Total.
1840.....	279	53	332
1841.....	228	23	251
1842	489	106	595
1843.....	455	60	515
1844.....	414	47	461
1845.....	449	26	475
1846.....	1549	197	1746
1847.....	1196	98	1294
1848.....	1048	153	1201

It should, however, be observed that the great majority of the diarrhœa cases occurred in children.

The author of the Report states:—"So far as the returns down to the end of September go, I may repeat what I stated three months since, 'that there is no trace of the epidemic cholera in England.' The subsequent weekly returns for London justify the suspicion then expressed, that the epidemic might, as in 1831, reach England in October,"—a suspicion which has unhappily been verified.

There is one remark we have to make, which, as bearing reference to the opinions of Dr. C. W. Bell, of Manchester, published some months back, in the *Medical Gazette*, may be worthy of consideration. In the London tables there is a small, though obvious, increase in the amount of mortality from remittent fever; the deaths from that disease in the September quarter of the years, 1841, 1842, and 1843, amounted to only five each. In the same quarter of the year 1844 they were thirteen; in 1845, eight; in 1846, twelve; in 1847, twenty-three; and 1848, eighteen. Bearing in mind that remittent fever in this country is rarely a fatal disease, we think that the increase of this affection, as far as London is concerned, must have been considerable within the last two or three years, —that is, during the period in which the epidemic cholera has been threatening Europe.

The present report affords us no materials for ascertaining the prevalence of intermittent and remittent fevers in the country districts during this period.

Reviews.

On the Ganglionic System of Nerves. By CHARLES RADCLYFFE HALL, M.D., M.R.C.S.E., &c. Part III. 8vo, pp. 77.

Some time back we had occasion to direct attention to the interesting experimental researches of Dr. Radclyffe Hall, on the ganglionic system of nerves. We have here the continuation of these researches. The part before us relates to the spinal and sympathetic ganglia of the fifth nerve, including the Gasserian, ophthalmic, spheno-palatine, and salivary ganglia; and the ganglia of the ear. The general scope and nature of the inquiry will have been sufficiently apparent from our former notice, as well as the manner in which the author has treated his subject. On the present occasion, we shall content ourselves with quoting the conclusions arrived at by Dr. Hall from a survey of the ganglionic relations of the fifth nerve.

1. "The organic actions of the parts supplied by the trigeminus are invariably associated with the impressibility of the same parts. Whether or not the subsidiary ganglia co-exist, the Gasserian ganglion is invariably present.

2. "The Gasserian ganglion is quite competent to, and sufficient for, the superintendence of the organic actions going on in the organs of the special senses, as well as in all other parts supplied by the fifth nerve, so long as these several parts are not directly connected and associated with the action of special muscles. *e.g.* The fish possessing an eye, ear, and nostrils, perfect of their kind, has none of the sympathetic ganglia belonging to the fifth. The eye is without its muscular iris, the ear without its tympanic muscle, the nostril without its moveable palate.

3. "Wherever we do find a distinct and essential connection and association between the organic actions of a part and the contraction of some special muscle or muscles, there we also find a distinct sympathetic ganglion superadded to that of the fifth. *e. g.* The ophthalmic ganglion exists only when the organic actions of the eye need be associated with the contraction of a *sphincter iridis;* the otic ganglion, when the organic actions of the middle ear with contraction of the *tensor tympani* and of other muscles; the acoustic ganglion, when the organic actions of the internal ear with contraction of the *stapedius:* the spheno-palatine ganglion, when the organic actions of the *nares* and *velum*, with movement of the soft palate; the salivary ganglia, when the organic activity of the glands requires association with those muscles of the oral cavity which are supplied by the facial nerve.

4. "But the converse does not hold good. The ganglion is not essential to the muscle. A muscle, for which a particular sympathetic ganglion is usually present, may yet exist without the ganglion. *e.g.* In birds and reptiles, an internal tympanic muscle exists without any otic ganglion. In them, the organic actions of the tympanum are not associated with the contraction of the muscle. In all those animals which possess an otic ganglion, they are. Hence the sympathetic ganglion is needed, not for the muscular contraction alone, nor for the organic action alone, but for combining the two.

5. "As the muscle which is animated by a motor nerve from the sympathetic ganglion, when this does exist, is equally animated by a motor nerve non-ganglionated, when the ganglion does not exist, we may infer that the ganglion does not constitute the centre of nerve-force for the motor nerve when the two happen to exist together.

6. "The impressional portion of the fifth nerve sends a contribution to each of the sensorial sympathetic ganglia. There can be no doubt that this arrangement ministers to sympathy between the internal parts supplied by the sympathetic ganglion and the related external parts supplied by the fifth nerve; at the same time that, by concentrating the impressional nerve-tubes distributed to the senses at their encephalic terminations into one large nerve-trunk, it admits of readier reaction either of these nerve-tubes at their origin upon each other, (impressional reaction,) or of these nerve-tubes upon motor ones, (motor reaction.) Seeing that the motor reaction of several of the senses is particularly upon one nerve—the facial—the convenience of the arrangement is evident.

7. "The glosso-pharyngeal and the vagus, which are the only other common impressional nerves of the encephalic, likewise send a contribution to each of the sensorial sympathetic ganglia, with the exception of the ophthalmic. In like manner to the above, will these contributions confer on the ganglia sympathetic relations with certain parts supplied by the two nerves of the eighth pair. The ganglia of the mouth, nostrils, and ear, are the especial servants of the mucous membrane, and can scarcely be too closely associated with it; accordingly they receive the contributions referred to. The eye alone, from its delicacy of structure, refinement of action, and peculiarity of function, requires to be removed from what would be to it the deranging influence of direct nervous connection with the mucous membrane. Hence the glosso-pharyngeal and vagus send no contribution to the ophthalmic ganglion. '*Exceptio probat regulam.*'

8. "The impressional contribution of the fifth to the sensorial sympathetic ganglia is special and peculiar to each, having no relation to any other sympathetic ganglion. The reverse is the case with the impressional contribution of the two nerves of the eighth. This is in every instance related to more than one of the sympathetic ganglia. It will result from this that impressions may excite ganglionic reaction on the part impressed without interfering with the ganglia of any other parts, through the filaments of the fifth; but cannot excite it in one ganglion without calling forth the co-operation of others, when acting through the filaments of the eighth. On this distinction I found the view that the sensorial sympathetic ganglia belong to the fifth nerve, rather than to the glosso-pharyngeal or the vagus.

9. "The motor element of each of these ganglia in every instance, is special and peculiar to its own ganglion, and has no relation to any other."

The Periodoscope: with its Application to Obstetric Calculations, and the Periodicities of the Sex. By W. TYLER SMITH, M.B, Lond., Obstetric Lecturer in the Hunterian School of Medicine. London. 8vo. pp. 45.

This simple and ingenious contrivance for facilitating obstetric calculations must be seen, and the accompanying observations read, to be properly appreciated. Its main use is to give at a glance the probable duration of gestation in any individual case to which it may be applied,

but, it also indicates, as the author justly states, the probable dates of occurrence,—1, of absorption, miscarriage, and premature labour; 2, of quickening, or the first uterine movements; 3, of the viability of the fœtus; 4, of the periods when premature expulsion may be induced artificially, most easily and most safely; 5, of the periods of special danger from hæmorrhage in placenta prævia; 6, of the coming on of labour; and 7, it affords, also, a complete calendar of the catamenia.

The instrument consists of a moveable disc, on which are marked the fifty-two weeks of the year, the calendar months, and days of the months, (we do not observe the thirteen lunar months, or ovarian periods, to be noted, as stated by the author, on this portion of the instrument;) of a fixed circle beyond this, containing a scale of the catamenial periods; and an outer segment of a larger circle, with a scale of 280 days divided into the ten catamenial cycles of gestation, with indications of the principle physiological and pathological changes likely to occur at each period. For a more detailed description, and for the mode of employing the "periodoscope," we must refer to the accompanying observations. It is sufficient to state, that no member of the profession engaged in obstetrical practice, should be without the "periodoscope;" and that those engaged in general practice will often derive useful information from its indications,—for instance, as a guide to the use of remedies in various forms of catamenial irregularity.

Foreign Department.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS.

WOUNDS OF JUNE.

The events of last June have, during the last months, afforded ample material for surgical discussion, and accordingly everything has given place to this subject of immediate interest. M. Roux, whose experience in gun-shot wounds has been extensive, commenced the debate by a discourse, which he divided into two portions, the one consisting of a general enumeration of the casualties, the second comprising his views on certain of the more debateable surgical questions. From its central situation, the Hotel Dieu received a large number of wounded, amounting in all to 451, of which 179, (168 men and 11 women,) fell to the share of M. Roux. The subjects were mostly young, and there deportment exhibited the utmost calm, in spite of the excitement to which they had been exposed; the mortality, nevertheless, was very great. M. Roux lost 25 within a few hours of their admission, and subsequently 35 have perished, making a total loss of 60, or thereabouts. The majority of the wounds were caused by bullets or other projectiles, and these were observed in most cases to have made a complete transit of the wounded part. The seat of the wounds were, as might be expected, various. The greatest variety was also noticed in the dimensions and form of the opening of entry and exit of the balls. As regards amputations, M. Roux performed 11 primary operations, of which six died,—viz., three at the shoulder-joint, one death; one disarticulation of the elbow, dead; one partial amputation of the foot, dead; two amputations of the leg, one death; three amputations of the arm, one death; one of the thigh, dead. Of five consecutive amputations there were—three of the thigh, two deaths; one of the arm, dead; one of the leg, recovery. The difference in the results (says M. Roux,) is so great, that it is difficult to avoid sentiments opposed to the precepts of ordinary practice. M. Roux insists upon the fortunate issue of amputation at the shoulder-joint, but he rejects disarticulation at the elbow as an operation opposed to all correct surgical rules.

Among the special accidents observed among the wounded, was an instance of hemiplegia of the left side, resulting from a musket shot through the scalp, without fracture of the cranial bones. There was no instance of tetanus, and but one of hospital gangrene. One case of consecutive hæmorrhage was noticed, consequent upon fracture of the upper-third of the humerus, which required ligature of the brachial artery.

In the second part of his memoir, M. Roux touches upon some of the manœuvres required by gun-shot wounds, and first of *debridement*. In his opinion this practice is advantageous under certain conditions, but as a general rule he abstains from it, unless there be risk of strangulation of the tissues, or acute pain. With respect to *foreign bodies*, he advises their extraction, if they can be readily got at, not otherwise. *Secondary hæmorrhage* he meets by ligature of the main trunk above the wound. M. Roux is no advocate for the continued application of cold, advised by some of his colleagues. He removes all splinters, and all fragments of comminuted bone, whenever practicable. Although in other cases an advocate for re-section of joints, in the case of gun-shot wounds he prefers amputation.

M. Baudens next laid before the Academy the results of his practice in wounds by fire arms. Of 164 cases received at the military hospital of Val de Grace, 28 died, 70 were cured, and 66, were at the time under treatment. Of 20 amputations 14 were primary, with three deaths; six were secondary, and all died. The speaker in continuation, examined several surgical questions in succession: 1. As to the "*debridement.*" He abjures this, and thinks the idea of relieving strangulated tissues by it as absurd. 2. *As to the propriety of removing splinters, &c., or leaving them to be eliminated by suppuration.* The author thinks they should be removed except in the case of the bones of the face. 3. Should refrigerants constitute the main treatment of gun-shot wounds? This he answers in the affirmative, believing the application of ice to be the most powerful means of moderating local reaction. 4. *When fracture of the bones of the extremities does not exceed certain limits, should amputation or resection be adopted?* The author makes a distinction between the upper and lower limbs; in the former resection is more difficult. We may resect the fractured portion of the tibia and fibula separately; fracture of both bones

generally requires amputation. Fracture of the thigh always requires amputation, whether comminuted or not. If the head of the bone is wounded, he regards resection as preferable to disarticulation at the hip. Every fracture implicating the knee-joint, however small in extent, demands immediate amputation. If the upper part of the tibia only is broken, we may try to save the limb. Fracture of the lower articulating end of the head of the humerus should be treated by excision rather than amputation. The same may be said of the shaft of the humerus when the splinters are few. At the elbow, excision is to be preferred, if one bone only is implicated; the same may be said of the carpus. 5. *Which offers most chance of success, primary or secondary amputations?* M. Baudens does not hesitate to pronounce in favour of the former.

To M. Baudens succeeded M. Malgaigne, who thus narrates his experience. In the hospital of St. Louis there were 490 wounded, of whom 120 died. In one case of fracture only was primary amputation necessary. Of 27 fractures in which he abstained from operating, fifteen were cured, eleven died, and one was subjected to secondary amputation, and also did badly. This speaker opposed himself strongly to M. Bandens, who makes amputation the rule in fractures from gun-shot wounds rather than the exception.

It is true, he admits, that to endeavour to preserve a thigh, fractured by a bullet, is to lose the greater part of the patients. But before we, on this account, have recourse to amputation, it is advisable to ascertain, what are the chances offered by the operation. On this point surgeons are greatly at variance. Boucher declares that two-thirds of the amputations die, especially those of the leg. Guthrie, at New Orleans, lost 1 in 7; at Toulouse 1 in 5. The English army in the Peninsula lost 1 in 8; Larrey 1 in 6. In the hospitals of Paris, of 165 amputations for wounds, 107 died, so that primary amputations are, upon the average, fatal to two out of three. In looking at this question in another light, that of non-amputation, M. Malgaigne refers to a document, in which Dupuytren states that of thirteen cases of fracture of the thigh in which he did not operate, he saved five and lost seven; and that of seventeen fractures of the leg, seven recovered and ten died; while of five primary amputations of the thigh, he lost three, and of four secondary operations he lost every individual. Whence it follows, that (*cæteris paribus*) the chances are more in favour of the patient by the endeavours to save the limb, than by removing it. The opinion thus expressed by M. Malgaigne, he has seen confirmed by the events of June. Thus of seventeen fractures of the thigh and leg treated without amputation, he obtained eight complete cures; and of twenty-five similarly treated by M. Gosselin, fourteen at least are in a fair way of recovery. This fortunate result he attributes a good deal to his mode of managing the cases. He abstains as much as possible from all *debridemens*, counter-openings, incisions, &c. His apparatus is also of the simplest character. He feeds his patients well, and is chary of bloodletting in every form. This practice he derived from a comparison of the results in 1814, when he found that in those who were subjected to a rigid diet, 1 in 7 died; while among the Russians who were fed well, the deaths were only 1 in 27.

COLLODION.

M. Malgaigne introduced some remarks on this article, and of course claimed it as a *French* invention.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

DIRECTIONS RELATIVE TO THE PREVENTION AND TREATMENT OF CHOLERA.

The Royal College of Physicians of London, feeling that, on the re-appearance of epidemic cholera in England, the public may naturally look to them for advice and guidance, have deemed it proper to appoint a cholera committee, composed of physicians who hold important offices in the metropolitan hospitals, or who had extensive experience of the disease at its last visitation, to consider what measures it is expedient to adopt, with a view of preventing the spread of the disease, and of otherwise mitigating its evils.

The committee thus formed have, in compliance with the wish of the College, drawn up the following remarks and instructions, for the information of the public:—

1st. Cholera appears to have been very rarely communicated by personal intercourse; and all attempts to stay its progress by cordons or quarantine have failed. From these circumstances, the Committee, without expressing any positive opinion with respect to its contagious or non-contagious nature, agree in drawing this practical conclusion: that in a district where cholera prevails, no appreciable increase of danger is incurred by ministering to persons affected with it; and no safety afforded to the community by the isolation of the sick.

2nd. The disease has almost invariably been most destructive in the dampest and filthiest parts of the towns it has visited. The Committee would therefore urge on the public authorities the propriety of taking immediate steps to improve the state of sewers and drains;—to cover those which are open;—and to remove all collections of decaying vegetable and animal matter from the vicinity of dwellings. They would also impress on individuals, especially of the poorer classes, the great importance of well-airing their rooms, and of cleanliness in both their dwellings and persons.

3rd. A state of debility or exhaustion, however produced, increases the liability to cholera. The Committee, therefore, recommend all persons, during its prevalence, to live in the manner they have hitherto found most conducive to their health; avoiding intemperance of all kinds, and especially the intemperate use of ardent spirits and other intoxicating liquors. A sufficiency of nourishing food; warm clothing, and speedy change of damp garments; regular and sufficient sleep; and avoidance of excessive fatigue, of long fasting, and of exposure to wet and cold, more particularly at night, are important means of promoting or maintaining good health, and thereby afford protection against the cholera.

The Committee do not recommend that the public should abstain from the moderate use of well-cooked green vegetables, and of ripe or preserved fruits. A certain proportion of these articles of diet is, with most persons, necessary for the maintenance of health; and there is reason to fear, that if they be generally abstained from, now that the potato-crop has in a great measure failed, many persons, especially amongst the poor in large towns, will fall into that ill condition, which in its highest degree is known as scurvy, and that they will in

consequence be the readier victims of cholera. The Committee likewise think it not advisable to prohibit the use of pork or bacon; or of salted, dried, or smoked meat or fish; which have not been proved to exert any direct influence in causing this disease. Nothing promotes the spread of epidemic diseases so much as want of nourishment; and the poor will necessarily suffer this want, if they are led to abstain from those articles of food on which, from their comparative cheapness, they mainly depend for subsistence.

On the whole, the Committee advise persons living in districts in which cholera prevails, to adhere to that plan of diet which they have generally found to agree with them; avoiding merely such articles of food as experience may have taught them to be likely to disorder the stomach and bowels.

4th. The Committee are unable to recommend an uniform plan of treatment to be adopted by the public in all cases of looseness of the bowels, supposed to be premonitory of cholera. It is, doubtless, very important that such ailments should be promptly attended to; but since they may arise from various causes, of which a medical man can alone judge, the Committee deem it safer that persons affected with them should apply at once for medical assistance, than that they should indiscriminately use, of their own accord, or on the suggestion of unprofessional persons, powerful medicines, in large and frequently repeated doses. Should the looseness of the bowels be attended with feelings of great exhaustiou and chilliness, the person should, of course, be placed in a warm bed, and the usual means of restoring warmth to the body be assiduously employed, until professional advice can be obtained.

5th. In order that the poor may have the means of obtaining such assistance promptly, the Committee recommend that the proper authorities should at once establish dispensaries in those parts of the town which are remote from the existing medical institutions; and that they should also take steps to provide distinct cholera hospitals, which it will require some time to organize, and which they believe will be found to be absolutely necessary, should the epidemic prevail in this metropolis with a severity at all approaching that which it manifested on its first appearance in England. The Committee wish it to be clearly understood, that they do not recommend the establishment of such cholera hospitals, on the ground of effecting the separation of the sick from the healthy, and of thus preventing the spread of the disease; but solely in order that, should the epidemic prove severe, proper attendance and prompt treatment may be ensured for the sufferers from cholera among the poorest and most destitute class. The existing hospitals, even if the authorities should consent to the admission of persons ill of cholera, could not furnish the requisite accommodation, unless they were shut against persons labouring under other severe diseases—a measure which, at the approach of winter especially, would add much to the distress of the poor.

6th. In conclusion, the Committee would urge on the rich, who have comparatively little to fear for themselves, the great duty of generously and actively ministering to the relief of the poor, while the epidemic prevails; bearing in mind that fuel, and warm clothing, and sufficient nourishment, are powerful safeguards against the disease.

They deem it most desirable that the parish authorities should at once improve the diet, and increase the comforts, of the poor under their charge; and that the wealthy should form societies for the supply of food, clothing, and fuel, to those who, though not paupers, still need charitable assistance in the present emergency.

Such measures, which it is the duty of those possessed of power and wealth to adopt, would, the Committee believe, if liberally carried out, deprive the cholera of half its victims.

JOHN AYRTON PARIS, President.
FRANCIS HAWKINS, Registrar.
College of Physicians, Oct. 28, 1848

POOR-LAW MEDICAL COMMITTEE.

UPTON UNION.

The following is a copy of a memorial which has been forwarded to the Poor-Law Board, by the Committee, on the subject of the recent resignation of Medical Officers of the Upton-on-Severn Union:—

To the Right Honourable Charles Buller, M.P., President of the Poor-Law Board.

The Memorial of the Committee of the Convention of Medical Officers of Poor-Law Unions in England and Wales

Sheweth—

That your memorialists being deputed and authorised at a Convention of Delegates representing nearly three thousand medical officers of unions, assembled at the Hanover Square Rooms on Oct. 27, 1847, to act in their behalf, with a view to obtain an amelioration of the present system of poor-law medical relief, feel it their duty respectfully to draw the attention of the Poor-law Board to the following statement:—

Your memorialists have watched with deep interest the circumstances connected with the recent resignation of the medical officers of the Upton-on-Severn Union, and the subsequent appointment of others by the guardians of that union to fill the vacancies thus created; and the feelings entertained by your memorialists on this subject are so strong that they do not hesitate to address your honourable board, to the effect that the case may be thoroughly investigated prior to those appointments receiving its sanction and confirmation.

Your memorialists, in thus calling attention to the subject, desire, in the first instance, particularly to state that they have taken no part whatever with the medical officers of the Upton Union, as respects any special grievance which they may have laboured under, and that their resignation has emanated from themselves without any bias or influence being exercised by your memorialists, who make this appeal upon public grounds, considering the followieg reasons amply sufficient to justify their doing so:—

1st. That, although the total amount of the salaries paid to the medical officers of the Upton Union may not be below the average paid to medical officers of agricultural districts, the scale of remuneration which is made the standard is so miserably degrading and inadequate as to give general offence to the medical profession, and both jeopardize the interests of the sick poor and prove a short-sighted economy to the ratepayers.

2nd. That the order limiting the extent of the districts of medical officers as ordered by your board has been violated by the guardians of the Upton Union, in assigning to their officers two districts exceeding the proscribed acreage.

3rd. That, as your memorialists are credibly informed, one, at least, of the medical officers appointed by the said union is not qualified in accordance with the judicious order of your honourable board for securing efficient medical aid for the sick poor; and that another of the medical men submitted for your approval was once suspended when holding office on a former occasion, and was even set aside by the very board of guardians which now considers him eligible to fulfil the onerous duties which his appointment necessarily imposes upon him.

4th. That the circumstances of the whole case are such as to foster dissensions amongst the members of the medical profession, and seriously to obstruct their co-operation for the benefit of the sick poor.

For these reasons your memorialists pray that you will be pleased to withhold your confirmation of the said appointments.

(Signed)

Thomas Hodgkin, M.D., Chairman of the Committee.

Charles F. J. Lord, Hon. Sec.

Sept., 1848.

NOTES FROM A PRACTITIONER'S DAY BOOK.*

AN EFFECT OF OPIUM, UPON WHICH SUFFICIENT STRESS HAS NOT HITHERTO BEEN LAID.

Opium increases the circulation of the skin, and diminishes that of the mucous membranes. A person who has taken a full dose of opium at night, will, amongst its other effects, feel himself the warmer for at least twenty-four hours afterwards. I am acquainted with a gentleman who has met with considerable success in his practice on indolent old ulcers, and one part of his treatment consists in his giving his patient a grain of opium thrice daily; this is done upon the principle of stimulating the capillary circulation of the part. In that form of deafness which is attended with tinnitus, and appears to consist in a congested state of the mucous membrane of the Eustachian tube and tympanum, I have often successfully prescribed opium with a view of increasing the cutaneous circulation, and diminishing that of the mucous membranes.

An old lady suffered from a severe attack of influenza, the poison of which seemed principally to operate upon the Schneiderian and bronchial mucous membranes. For four years afterwards she constantly suffered from an obstruction in both nostrils, attended with so profuse a secretion of thin mucous fluid, as to oblige her to use four or five handkerchiefs in the course of the day, and the least exposure of the lungs or surface to a cold atmosphere brought on an asthmatic attack, which was accompanied with a copious frothy expectoration. Though she could smell nothing which was presented to her nostrils, she was troubled with an offensive putrid odour, which she imagined was always present, whilst the sense of taste had become so obtuse, that she could neither distinguish tea from water, nor salt from soda. I had been acquainted with her for a long time, and had frequently prescribed various remedies without success, as a great many other practitioners also had done. The mucous membrane of both nostrils was swelled, redder than natural, and so acutely sensitive, that she could not bear the slightest touch with my probe. These symptoms and appearances might have induced me to the opinion of the case being one of malignant polypus; but though the disease had existed so long without any amendment, it had, on the other hand, made no advance; and besides this circumstance, the history of the case, and the co-existence of the thoracic affection, were not in favour of this supposition. One morning, whilst sitting near her, and witnessing the constant annoyance from which she was suffering, I remembered that, whilst I was attending her for an acute disease, by which she was confined to her bed, she mentioned that her head and chest symptoms had suddenly become much better, for she had barely wet a single handkerchief, and fancied she had perceived the savoury odour of a stew, which was being prepared in the kitchen. I paid no attention to this circumstance at the time, especially as, a few days later, I noticed that she again seemed as bad as ever. But now, and it was at least a twelvemonth afterwards, a bright thought struck me; I remembered that, at the time she spoke of this amendment, she was taking opium in considerable quantities, for a spasmodic pain in the bowels. My opinions on the effects of opium, which I have above detailed, were already formed, and I determined upon having recourse to it in this instance. I laughingly told her that a brilliant idea had come into my head, and that I now knew what would give her relief. The good old soul shook her head doubtingly, and said that she would give me fifty pounds if it did. (She never paid me, if she meant it.) Desirous of concealing the nature of the remedy, I prescribed the Pilula Styracis Composita, in five grain doses, every night at bed-time. Some improvement was apparent in the course of a very few days, and it became continually progressive. In two months she ceased to wet more than a single handkerchief daily, and had even some return of the sense of smell and taste, whilst she had now become comparatively indifferent to a low atmospheric temperature; for although during the whole of the previous winters she had been obliged to confine herself to one room, or to move through the passages with a shawl, or a respirator, before her mouth, during the next cold season she wandered about the house, without finding any precaution necessary. She always had expressed herself with extreme confidence of the benefit she had received, and as a proof of her faith, I may mention the great glee with which, during her last illness, she received the intelligence that I allowed her to have one of her old pills; those pills she believed would cure every malady. She died of another complaint, seven months after the commencement of this treatment, but I believe that the improvement in her head and chest symptoms had been progressive to the last.

Opium eaters generally complain of feeling cold and shrunk up, when they are deprived of their habitual stimulus. These effects of opium on the mucous membrane are well illustrated in the following passage,

* Continued from page 584.

which is taken from the "Confessions of an English Opium-Eater":—

"I must mention one symptom which never failed to accompany any attempt to renounce opium,—viz., violent sternutation. This now became exceedingly troublesome, sometimes lasting for two hours at a time, and recurring at least two or three times a day. It is remarkable also, that during the whole period of years through which I had taken opium, I had never once caught cold, nor even the slightest cough, but now a violent cold attacked me, and a cough soon after."

TRAUMATIC TETANUS.

A man died from traumatic tetanus, following an injury of the foot, produced by his treading upon an upright nail. On a *post-mortem* inspection, the plantar nerve was found torn through one half its diameter, and there was lodged between the extremities of its lacerated fibres, a portion of boot leather, which had been pushed inwards by the nail.

THE INTENTION OF HICCUP.

In the convulsive movement of hiccup, the diaphragm is depressed; the larynx is raised; and the glotttis is closed. What would be the effects of these conditions? The depression of the diaphragm would tend to expand the cavity of the chest; but the glottis being closed, no air can enter the lungs. The two extremities of the œsophagus are, however, still open, and if the hiccup be strong enough, air will enter the œsophagus at both ends. If a person will make a prolonged voluntary effort of the conditions which occur in hiccup, he will find a portion of air sucked, as it were, into the œsophagus, from the pharynx. Now, spasmodic hiccup is a reflex movement, excited, in general, by gaseous irritation of the stomach; under these conditions the hiccup will suck the air of the stomach into the lower extremity of the œsophagus. This, then, is the intention of hiccup,—to pump off the air of the stomach. The movement of the hiccup sucks the gaseous contents of the stomach into the lower extremity of the œsophagus, and an inverted action of the œsophagus propels them upwards, and discharges them at the pharynx.

General Retrospect.

PATHOLOGY.

ON THE ARTIFICIAL INFLATION OF THE LUNGS, IN NEW-BORN CHILDREN, AND ON ATALECTASIS PULMONUM.

Dr. Eulenberg adverts to the discrepancy of opinion as to whether the lungs of a still-born child can be so inflated as to swim in water. The affirmative has been maintained by Bohn, Lieberkühn, and Hunter; the negative by a greater number, and is the prevailing opinion. The present author has repeated experiments, and as the result, has found that the effect of inflation much depends upon the period at which it has been commenced. He states,—1. That the inflation is always easy if undertaken shortly after birth, before rigidity has taken place; the effect being complete in proportion to the force used. 2. Inflation is difficult after rigidity has commenced. Dr. Eulenberg then reviews the points of difference which are usually said to distinguish inflated lungs from those in which respiration has taken place.

1. *Inflation produces a complete distension of the organ.* This in fact depends entirely upon the degree and duration of the inflation, and from its not being delayed until collections of mucus or other causes offer mechanical obstacles to the admission of air. 2. *Abscence of crepitating sound on section.*—3. *Expulsion of air by pressure.* Air is expelled with as much difficulty after artificial inflation as after respiration. In neither case is the buoyancy of the lungs destroyed, but by such an amount of pressure as destroys their texture.—4. *Bloodless colour of the lungs.* This is too variable to form a ground of distinction.—5. *Colour of the distended lung.* This is a greyish dirty red, very different from the bright red of a lung which has respired.—6. *Substance of the lung.* Upon the surface of the inflated lung, just under the pleura, are to be seen small flat roundish vesicles, the size of a millet seed, disposed in groups, forming a vesicular emphysema. The stronger the inflation, the more numerous are the isolated vesicles which are caused by the rupture of the texture of the lungs. When inflation induces this emphysema over a great portion of the lungs it cannot fail to be recognized; but when a small portion only is so affected, it has the greatest resemblance to a pathological condition of the lungs of new-born children. In children born with atalectasis pulmonum, and who have lived for some time, are often found under the fœtal portions of lung, certain emphysematous spots like those produced by inflation. The following are the chief points of difference:—In atalectasis, the emphysematous portions project more from the surface, the lung is of a brighter red, richer in blood, closer in texture, its dark colour being but little influenced by pressure; the mucous membrane of the bronchi is red and swollen. However, in emphysema from inflation, air is found in other parts as in the cellular tissue, near the thymus, œsophagus, &c. In a child with atalectasis, that has lived some time, the lungs, though in a fœtal condition, shew little tendency to sink, while in the inflated lung, all parts not distended sink immediately.

In three cases of atalectasis the author found the bronchial tubes obstructed by viscid reddish mucus, which he is inclined to regard as the main cause of their non-inflation by ordinary respiratory efforts, and for this reason considers tartar emetic as a remedy He objects to artificial inflation in the new-born infant, as if air is blown forcibly, an emphysema will always result.

The author's conclusions in reference to the lung-test are:—1. That we possess sufficient characteristic signs of a lung having been inflated. 2. That decomposition nullifies all tests.—*Medicinische Zeitung*, No. 6, 7, 8, 1848, and *Brit. and For. Med. Chir. Rev.*, Oct.

SURGERY.

INFLUENCE OF ÆTHERIZATION ON THE MORTALITY OF SURGICAL OPERATIONS.

In the April number of the *Monthly Journal*, Dr. Simpson has published tables showing the influence of ætherization on operations. From these it appears that of 230 primary amputations of the thigh, leg, and arm, performed in the British Hospitals *wihout the use of æther* there were 88 deaths, or 38 per cent.; of 388 secondary operations, 95 deaths, or 24 per cent.

Of 302 amputations of the thigh, leg, and arm, *under ætherization*, 73 were primary, and 25 deaths followed, or 34 per cent; 229 were secondary, 46 deaths, or 20 per cent. only.

In amputations of the thigh alone the difference is more marked, the per centage being as follows:—*Without æther*, in the Parisian Hospitals, 62 in 100; in the British Hospitals, 38 in 100. *Under ætherization*, 25 in 100.—*Monthly Journal.*

SUCCESSFUL AMPUTATION OF THE THIGH AT THE HIP-JOINT.

M. Guersant operated, on the 28th December, 1847, for a cancerous affection of the femur by disarticulation at the hip-joint. The child, aged 5, was very much reduced. He was put under the influence of chloroform —insensibility was complete in two minutes. The operation lasted only two minutes. When the ligature was being placed on the vessels the child became pale, a little foam came from the mouth, the eyes were turned up, and the pulse at the wrist disappeared. This state of syncope was dissipated by means of active ventilation, and the introduction of a few spoonfuls of wine into the stomach—and the child began to cry, much to the relief of the surgeon. Twenty-two days after the operation the child was as well as possible.—*Journ. de Méd. et de Chir.*, Fevr., 1848.

DESCRIPTION OF A SIMPLE TRUSS IN CONGENITAL HERNIA.

Mr. Coates, after noticing the difficulty in maintaining a truss or bandage in position, in the case of infants, mentions a simple contrivance, from which he has experienced uniformly good results.

It consists of a skein of Berlin wool, which is made to encircle the pelvis, one end passing through the other at a point corresponding with the inguinal ring; the end thus passed through is then carried between the thighs, and fastened to the cincture behind. This can be worn at all times, and replaced and cleaned with little trouble, and, moreover, is not likely to gall the tender skin of the little patient.—*Medical Gazette*, Sept. 29th.

NEW MODE OF DILATING STRICTURES OF THE URETHRA.

M. Amussat, in a case of stricture which resisted all treatment, and beyond which ordinary instruments could not be passed, finally succeeded in introducing a very fine bougie of half a millimeter, (the millimeter is equal to 1-26 of an inch English,) and, using this as a conductor, on the following days introduced alongside of this successively several others, to the number of six. Between these the urine passed. They were left in for several days, being occasionally withdrawn and re-introduced in a bunch, passing as easily as a single bougie of the same size would. The stricture was now readily dilated with ordinary instruments and the cure rapidly effected. The advantage of this method is, that when once we can introduce an instrument, however small, there is no liability to failure in introducing the bougie a second time if once withdrawn, or in attempting to pass a larger one. Whatever is gained is maintained, and the first introduced serves as a guide to other instruments of the same size. The dilatation can thus be readily accomplished, and the urine passing between the small bougies they can be retained several days without inconvenience.—*Journ. de Méd. et de Chir.*, Fevr., 1848.

QUEEN'S COLLEGE, BIRMINGHAM.

PROFESSORSHIP OF PASTORAL DIVINITY.

We have to record another instance of the munificence of the Rev. Dr. Warneford to this establishment, which, though not immediately connected with the Medical Department, cannot but tend materially to contribute to the efficiency of the College at large. The Rev. Vaughan Thomas, in a communication to a special meeting of the Council, summoned for the occasion, made the announcement of Dr. Warneford's intention of endowing a Professorship of Pastoral Divinity. After noticing the general objects contemplated in the establishment of the College, and the means which had been taken to further these objects, the Rev. Gentleman proceeded to unfold Dr. Warneford's views in relation to the special purpose for which the meeting had been called, concluding his able address as follows:—"In the offer about to be submitted to the Council, our ever watchful benefactor was not unmindful of the Royal example. Her Majesty the Queen, (to whose grace and favour we are indebted for our collegiate existence—and not for that alone, but for that new and increased power of usefulness with which her Majesty has entrusted us by a Charter of greater amplitude,) by Royal Grant to the University of Oxford, bearing date May 3, 1842, assigned out of the Church revenues a large annual income to a Professor of Pastoral Divinity. The very course of his Lectures is set forth in the grant—they are to *comprehend instruction in the Ministerial duties, in the composition and delivery of sermons, in reading the Services of the Church, in the history of Liturgies, in the reason and use of Rubrics, and the like.* He is, moreover, *to give professional instruction, and to make examinations of the pupils according to such scheme or schemes as may from time to time be revised and altered by the authorities of the University.* In these words and acts of the Royal care and concern for the due discharge of the pastoral duties, Dr. Warneford beheld not only the brightness of the Queen's example, but the power of her authority. Having long entertained the pious wish of making the senior department of Queen's College available for the purpose of training good and sober-minded young men,

with scanty pecuniary resources, for Holy Orders, could Dr. Warneford have done better than tread, at whatever distance, in the footsteps of his Sovereign? Could he, in making provision for pastoral instruction in Queen's College, do better than follow the light of the Queen's example, and show respect to the wisdom of her Royal ordinance? There can be but one answer to these questions in a College and in a Council, created by the Queen's grace and favour, to carry out and onwards suitable courses of Collegiate education for the adults, as well as juveniles of the Midland Counties who are intended by their parents respectively for the various businesses of life, spiritual as well as secular. Nothing more remains than now to lay before this meeting Dr. Warneford's proposition:—He proposes, then, to give the sum of £2000 to trustees for the endowment of a Professorship of Pastoral Divinity in the Queen's College, Birmingham, to the intent that students who intend to be candidates for Holy Orders in our Church, may be taught the *Ministerial duties in their various branches, as also the composition and delivery of sermons, the reading of the Church Services, the History of Liturgies, the reason and use of Rubrics, and all other matters connected with, and subservient to, a faithful and efficient performance of what the Church requires of her Pastors and Ministers for the edification of their flocks.* This sum, invested by the Trustees after the manner of former investments of our great benefactor's many former grants, will yield in the shape of rent-charge £80 per annum for the Pastoral Teacher's stipend. In conclusion, a hope may be now expressed, that Dr. Warneford's example in this endowment may be followed, and the appeal made June 5, 1848, may produce endowments of other Professorships in Law, in Civil Engineering, in the different branches of science connected with the making and manufacturing of the articles useful or necessary to the well-being of social life, or which, as works of taste and elegance, add beauty to usefulness, and excite our admiration whilst they supply our wants."

Every effort is making to increase the efficiency of the several departments of this valuable Institution for the midland counties, and the members of the medical profession are especially appealed to for donations of pathological specimens to the medical department of the museum.

MEDICAL ASSISTANT.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Permit me, through the medium of your Journal, to expose the following case to the profession:—

About a month ago, I engaged as an assistant, a person calling himself Mr. S. Saunders: he referred me to Mr. H. Hewson, Reigate, and in reply to a letter thus addressed, I received a letter signed H. Hewson, strongly recommending him. In a few days my suspicions were excited as to the veracity of this letter, and his subsequent conduct having confirmed them, I made inquiries at Reigate, and have ascertained (through the kind assistance of an esteemed member of the Association,) that no one named Hewson is known there. The postmaster had, however, received a note purporting to be written by H. Hewson, and requesting that letters addressed to him might be forwarded to a certain place in London. This note is in Saunders' hand-writing, and the police have ascertained for me that he was resident at the place to which the letters were to be sent!

I have made this statement as concise as possible; but shall be happy to afford further information to any gentleman who may require it.

As a person who has already adopted two names, may, very probably, assume a third, I subjoin a description of him:—He appears about 35 years of age, about five feet eleven inches high; rather thin, and very upright. His complexion is very dark, eyes black, large black bushy whiskers, and, while resident with me, he wore a wig. His voice is very sharp and sonorous.

By publishing the above particulars, you will greatly oblige

Your obedient servant,
R. W. WATKINS, M.R.C.S., L.S.A.

Towcester, Oct. 14, 1848.

THE MEDICAL DIRECTORY.

The great improvement which was evinced in this useful publication last year, induces us to hope that the members of the Provincial Medical and Surgical Association, and others of the medical profession, resident in the provinces, have not neglected to avail themselves of the opportunity of the circular lately issued by the Editors. If any gentlemen should have hitherto omitted to reply, we trust that they will at once afford to the spirited proprietors all the information in their power. The work is one in which all are interested, and as it seems likely to be the only record of qualified practitioners which we are likely, for some time at least, to possess, it is well worthy of some slight effort to make it as correct as practicable.

TRACHEOTOMY IN LARYNGITIS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

My attention was attracted by the case, reported in the last number of your Journal, of Laryngitis, furnished by Mr. May, of Reading. It appears that a fatal termination took place in two days. Mr. May says, "Tracheotomy was considered but not performed, in accordance with the prevailing medical opinion in this country." It was ascertained after death, that the inflammation did not extend below the larynx; and Mr. May, in my opinion, very properly remarks, that, "in future cases, unless there existed positive evidence that the trachea and bronchi were involved, he would take the chance of laryngotomy."

In order to encourage him and others to give the patient the benefit of the chance of this operation

in this terrible disease, I beg to relate a case which a few years ago occurred in my practice.

Case.—John Springer, a carpenter, about 50 years of age, of intemperate habits, was attacked with symptoms of laryngitis, but not at first of a severe character. He was not a subject for general bleeding. Leeches and blisters were applied, and calomel and antimony administered. On the evening of the second day a great aggravation of symptoms occurred, threatening speedy suffocation. I sent hastily for my neighbour, Mr. Smith, the surgeon, and in a few minutes I placed a tube in an opening made through the crico-thyroid membrane, apprehending every moment the patient would breath his last, before he could be got out of bed within our reach and the operation performed.

The result was most favourable. Immediate relief followed the operation and the disease rapidly subsided under the constitutional effects of mercury. I saw this man in the street a few days ago; he has been perfectly well ever since.

I am, Sir, your obedient servant,

N. ADAMS.

Lymington, Nov. 3, 1848.

Medical Intelligence.

THE UPTON UNION.

We understand that the three vacant districts of the Upton-on-Severn Union,—namely, Powick, Kempsey, and Eldersfield, have been accepted by Messrs. Wadams, Crosse, and Shuard, without any increase of the original salaries. Mr. West of Great Malvern, who attended the Powick district *pro tempore*, has forwarded the amount of his stipend to the clergyman of Barnard's Green, Great Malvern, for the benefit of the poor of that district.

APPOINTMENT.

Mitchell Henry, Esq., has been elected Assistant Surgeon to the Middlesex Hospital.

ROYAL COLLEGE OF SURGEONS.

Gentlemem admitted Members on Friday, November 3rd:—W. B. Wall; J. Elkington; T. Newham; M. W. B. Coulcher; J. Falconer; J. F. Pellegrin; B. Marsack.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, October 26th, 1848:—James Henry Lakin; Halsted, Atherstone, Warwickshire; Edward Gylles Crooke, Edinburgh; William James Williams, India; Henry Potter.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

BATH AND BRISTOL BRANCH.

John Colthurst, Esq., F.R.C.S., of Clifton, has been appointed Secretary for Bristol, in the room of G. H. Hetling, Esq., resigned.

BOOKS RECEIVED.

An Introduction to Practical Chemistry, including Analysis. By John E. Bowman, Demonstrator of Chemistry in King's College, London. London: Churchill: 1848. pp. 280. Wood-cuts.

MEDICAL & SURGICAL JOURNAL.

LECTURE ON THE NATURE & TREATMENT OF CHOLERA,

CONSIDERED WITH REFERENCE TO ITS

ANALOGY WITH CONGESTIVE AGUES OF QUOTIDIAN TYPE.

By Charles W. Bell, M.D., K.L.S.,

Physician to the Manchester Royal Infirmary, &c., Consulting Physician to the Ancoat's Dispensary, One of the Vice-Presidents of the Manchester Medical Society, late Physician to His Majesty's Embassy, in Persia, to the Royal Household and Army of Persia, &c., &c., formerly House-Surgeon to the Middlesex Hospital.

(Read before the Medical Staff of the Manchester Royal Infirmary, and the Members of the Medical Profession in Manchester, October 27th, 1848.)

Gentlemen,—

Both as students of the science of medicine, and as professors of the healing art, we are all at present peculiarly interested in investigating the nature of cholera. Thirty-two years have now elapsed since that fatal disease first became known to our countrymen in India, and through them to the inhabitants of other countries; but it was long regarded by the nations of Europe and America, as belonging rather to another world, than as ever likely to become personally interesting to themselves.

It was only on its actual appearance among us in 1832 that we became convinced of our mistake, and were thrown into all the consternation that attends a mysterious and unexpected object of terror. At that time every human attempt made to arrest its progress proved in vain; and, setting almost every variety of climate at defiance, cholera completed the wide circuit of the world.

No sooner, however, was the danger past, than we relapsed into our false notion of security, until this was again dispelled by appalling accounts of its renewed progress through Asia, and of its having again passed the boundary of the Caucasus, invading Europe by the identical route which it had followed seventeen years before, with no other difference than that its front was now more extended.

It might reasonably have been expected that, after the disease had extended itself over nearly the whole globe, and the press of every country had absolutely teemed with essays upon the subject, some definite agreement would have been arrived at by the profession with regard to its essential nature, and to the principles upon which its treatment should be conducted. It is, then, little flattering to our professional pride, to be obliged to acknowledge that this expectation has been disappointed.

The medical press gives almost daily evidence, that little information of importance has been added to that which had been collected by the earliest observers of the disease; our practice is still almost entirely empirical, the principles on which it should be conducted are as little determined, and the opinions of the profession as little settled as they were on its first visitation.

Even the great question of the capability of cholera being communicated by contagion, is still a moot point, and all the evidence collected on the subject is insufficient to convince our legislature that quarantine regulations in regard to it, are only a useless and cruel grievance. Under such circumstances, and after many of the first medical authorities of the past and present generation have failed to elucidate its nature, it is only natural that every new attempt to throw light upon the subject should be received with distrust, and that any one who now ventures on the discussion, will do so at considerable risk to his professional reputation; I cannot, therefore, but feel much diffidence in doing so, and that much apology is due to you for requesting your attendance here for that purpose.

My reason for making the attempt is, simply that I believe the circumstances under which I have had an opportunity of studying the disease have been peculiar, and such as to lead to conclusions of great importance, and that I should be acting little in unison with the spirit of our profession, and be neglecting a great duty, if I failed in laying that information which chance has accorded me, before its members. I may, it is true, have overrated the value of my opportunities (this is for you to judge,) but believing, as I do, that what I have witnessed, if fairly set forth, will lead to the determination of a *principle*, rather than a rule of practice, I have felt it imperative on me to submit the subject to your consideration, in the same light in which it had appeared to myself.

After becoming acquainted with cholera, under very favourable circumstances, in Edinburgh, in 1832-3, and in London, in 1833-4, it was my lot to be stationed for several years in Persia, a country, situated both geographically, and in point of climate, midway between India and Europe, and there I had the opportunity of observing closely the first approaches of the identical cholera, which is now sweeping irresistibly towards us.

The disease was there ushered in by a regular succession of epidemics, commencing in a fever apparently continued, but by and by assuming more the character of a remittent, and this very gradually changed to an intermittent of quotidian type; of this the cold stage gradually became prolonged, and assumed all the appearances of an attack of cholera, and then came the cholera, as it has everywhere been known, without any *obvious* stages or intermission. This again in its turn disappeared, and the epidemic resumed the character of remittent and continued fever for a time. These various changes occupied a period of eighteen months.

Having thus witnessed the disease analysed and dissected as it were, into its component parts, and seen continued fever gradually resolve itself into cholera, and cholera into continued fever, by slow gradations, in a manner which does not appear to have ever been presented with the same perspicuity to any author, having, too, been obliged to follow each varying type of that epidemic with appropriate treatment, I have been led insensibly to those views of the nature and treatment of cholera, which I shall endeavour to submit to you, as shortly as may consist with my intention of leading you into the same train of reasoning which I myself pursued.

By considering this fatal disease rather as an exaggerated example of others better known, and whose treatment is more familiar to us, than as something anomalous and unlike every other disease, we shall, I trust, escape the necessity for vainly searching for some principle capable of reconciling modes of treatment so much at variance as hot air-baths and warm stimulant potations on the one hand, and snow-baths and iced-drinks on the other. Æther, alcohol, tartar emetic, calomel, lead, lunar caustic, croton oil, naphtha, assafœtida, quinine, opium, peppermint, bleeding, blistering, and the actual cautery, are only a few of the remedies that have been proposed for the same stage of the same disease, all equally failing—all equally recommended as infallible.

Still, there is one valuable conclusion to be drawn from the very contrariety of the means employed, viz., that almost all have felt that the more obvious indications (which the well-marked symptoms of cholera would lead us to follow,) are not to be trusted as guides in the treatment of the disease; that some broader principle is necessary to direct our practice than the fallacious one of opposing the cold of the body by external heat, the collapse and sinking of the vital powers by stimulants, or the purging and muscular spasms by opium. Indeed, the abandonment of this method of treating symptoms, and the loss of faith in heat and stimulants are what chiefly distinguish the more recent works of experienced authors from those of more ancient date, and of less practical acquaintance with the disease.

In concluding these prefatory observations, I beg to remark, that I have endeavoured to avoid discussing the opinions of others, because this is unnecessary to the audience I am addressing, who are not only well acquainted with the works of the best authors on the subject, but also possess a large amount of unpublished knowledge of the disease from their own practical experience.

The similarity of cholera to the cold stage of ague is too obvious not to have occurred to many, but there were, unfortunately, two circumstances which contributed much to prevent this analogy from being pursued to its full extent—the first being the want of any *obvious* stage of reaction, relaxation, or intermission; the other, that quinine and arsenic were not found effectual in the treatment.

It was observed that recovery from the cold stage of cholera in this country, was not unfrequently followed by a low form of continued—I should rather say remittent-fever, and this, instead of being regarded as one of the modifications of the disease, induced by climate, or, as a secondary effect of primary disorder, was considered by too many as the hot fit which belonged to the protracted cold stage that had preceded it.

I shall endeavour to point out that this form of fever not unfrequently precedes and follows cholera as an epidemic, even at long periods, before and after the appearance of the major malady, and sometimes occurs as its substitute; and that while it prevails in a country, the "epidemic constitution" to which it belongs, more or less influences the course of almost every other form of disease, by producing a greater than usual tendency to venous congestion, and diminished or irregular action in the capillary circulation; and that the type of sporadic fever in this country has for several years approached very nearly to this, especially in the last few weeks;—as also in Edinburgh in 1843, in Liverpool in 1844-5, and has been more particularly displayed in those cases of fever that have arisen spontaneously from putrid vegetable matter.

Finally, I hope to convince you that the alliance of cholera with other diseases, of which quotidian periodicity is a marked characteristic, gives us reason to believe that even when apparently most destitute of regularly recurring periods, it is not utterly so in reality. That it is, in fact, by considering cholera as an aggravated congestive ague of quotidian type, that we shall most nearly arrive at just principles on which to conduct its treatment, and that the means by which cure is effected in the one, are both theoretically and practically those which are most appropriate to the other.

DISTINCTION BETWEEN MALARIOUS AND CONTAGIOUS FEVERS.

Before we enter on the consideration of those diseases with which cholera is allied, and of which class it may be considered one of the extremes, it will be well to devote a few minutes to consider the broader points of distinction between this class and those diseases which are communicable by contagion.

By active disease, we mean either the direct effects of toxical or mechanical injury to some portion of the system, or the indirect effects produced by the resistance opposed by the vital powers to the operation of such causes—or, lastly, the effects of the struggle between the noxious influence and the vis medicatrix.

Fever is the most obvious and most frequent evidence of the activity of the vital powers to resist a noxious

influence, and of the attempts of the powers of life to repair the effects or remove the cause of injury; but in considering fever in general, it is usual to limit the term from its wider sense to that condition which follows the absorption of certain poisons into the blood. When, therefore, we find fever to be the consequence of absorbed poison, it is of the utmost importance to endeavour at the outset to ascertain, as nearly as we can, upon what part of the system, and in what manner the effect is produced, and what are the actions by which its influence is resisted.

That the cause of both contagious and sporadic fever is introduced into the system by the blood, few indeed doubt; but the important question is, does the cause produce its effects directly on the blood itself by essentially changing its constitution, or is it only conveyed by the blood, like digitalis, aconite, opium, &c., and without causing any essential change upon the blood, operate by affecting the nervous system?

In an admirable essay on "Spotted Typhus," read before the Provincial Medical Association in August, 1848, Dr. Davies, of Bath, drew a broad distinction between the two classes of poisons which are known to produce fever, viz., animal poison, and malaria. There is one kind of poison, he said, which, arising in the blood, and finding the elements of its reproduction in the blood of another, produces a fever capable of being propagated from man to man; and there is another class of poisons, which, arising in elements extraneous to the blood, does not find its elements there, and though it produces fever, cannot reproduce itself, and is not capable of being propagated from one to another.

The second class is that which is now to occupy our attention, at least, that portion of it which embraces fevers produced by malaria, whose characteristic is periodicity,* and I shall venture to enunciate the proposition with regard to these even more broadly:—That although the first class of poisons—that, namely, which produces the exanthemata,—operates on the blood and changes its constitution, the second operates not on, but through, the blood, and produces its effects by its agency on the sympathetic system.

Both classes no doubt produce effects on the sympathetic, but the first, (the animal poison,) acting by a continuous irritation, produces a persistent effort of the emunctuaries to remove the poison from the blood, or continued fever; the second, (malaria,) acting solely by nervous impression on the sympathetic, produces merely a struggle between the impression which is opposed to vitality, and those sensations and actions that are provided for the maintenance of animal life. This struggle is what we observe to take place in the intermitting and congestive fever, &c.

If malarious poison actually changed the constitution of the blood, it would be as impossible to cut short a fit of ague as an attack of small-pox or scarlatina; but it is possible to cut short an ague, by means which (as we shall see when we consider the treatment of intermittent,) are not one of them calculated to produce an essential change on the blood itself. There would, too, in all probability, be some evidence of an elimination of the poison by the fit, as by the skin in the exanthemata, which there is not; or some difference in the blood drawn several hours before and after the fit; but in both cases it is equally incapable of propagating the disease by inoculation. Besides, it appears scarcely possible to account for the leading characteristic of the whole class of these fevers—their periodicity—on any principle but by the law of nervous impressions,—viz., that long-continued impression of an object upon a nerve of sensation impairs its sensibility, but that a change of impression restores it; as the eye long fixed upon a point becomes insensible to the impression of light, but recovers its sensibility on being turned to other objects.

So the continued impression of the poison on the sympathetic subdues its sensibility to its appropriate stimuli,—namely, that excitability which resides in the vital organs, whose action the sympathetic governs and regulates, but its irritability becomes re-excited, and its energies are restored by the new impression caused by change from a natural to a disturbed condition of the organs, which is the consequence of the withdrawal of the influence that combines and regulates their functions. Like the eye, restored to a sensibility to light by change of object, where the energy of the sympathetic is thus restored by the new impression, the recovery of its natural sensibilities would be permanent, were it not again submitted to the same influence by which it had been paralysed at first; but as the optic nerve will again become insensible when the gaze is again fixed as before, and this sooner or later, as the object is more or less illuminated, so does the sympathetic require to be again undisturbedly submitted to the noxious impression after recovery of its sensibilities before the effect is again produced, and that for a longer or shorter time, according to the power of that impression.

If we shall see reason to believe that the effects of the malaria under consideration are not caused by actual change operated on the blood, it will be evident that they can only be produced through the agency of the sympathetic, for we shall have frequent examples of malaria, affecting at one time the circulation merely, as in ordinary ague; at another only the bowels, as by diarrhœa or nervous constipation; at another the cerebro-spinal system, with convulsion, paralysis, or neuralgia; or, again, we have either two combined, or all three, as in cholera; and we know that with the exception of the blood, there is no other element in the system but the sympathetic, which is in such intimate contact or connection with the organs of circulation, of digestion, and with the cerebro-spinal nerves, as to be capable of producing these effects.

We find, too, that what we should expect from our acquaintance with anatomy, really is the case,—viz., that the capillary circulation is the part of the system which most frequently, most easily, and most completely, submits to the influence of malaria acting

* Some malarious poisons do undoubtedly contaminate the blood itself, and require special action for their elimination, as the Egyptian plague by boils; but these form a distinct genus of contagion, and do not fall under our immediate consideration. Those now to be discussed are all characterized by intermitting action till they reach their climax in cholera.

through the sympathetic, because almost every other part of the system,—the heart, stomach, lungs, viscera, &c., are all supplied by other nerves, the capillaries alone depending entirely on the agency of the sympathetic, whose branches are distributed to every, (even the minutest,) vessel in which our instruments enable us to trace it. This view is further borne out by considering the change from the healthy functions of this part of the system that are manifested when influenced by the morbid impression. In a state of health we know that certain chemical reactions take place between the blood and the terminal structures of the capillaries, by which perpetual slow absorption and deposition of the tissues, is effected, certain secretions are produced, and animal heat is evolved, and that while those actions go on undisturbed, the blood flows freely and unimpeded through the gently distended, but still very minute, veins, without exhibiting the least tendency to adhere to them, as would be the case in inanimate capillary tubes of equal diameter; neither does the contained blood exhibit any tendency to coagulate. We know that this property of preventing capillary adhesion of the blood to the coats of the vessels, and of preserving the fluidity of the blood, is peculiar to the living inner coat, and not to living structures generally, for extravasated blood, in whatever part of the body, immediately coagulates. We are also aware that the capillary circulation possesses local excitability, (independent of the heart,) and the power to resist injury or repair its effects, and that excitability is a reflex action, commencing in sensibility, therefore that this latter quality depends upon the nerves of the vessels.

To prove that all these qualities are bestowed by the sympathetic nerve would lead us too far from our present object; suffice it to remark, that the first stage of ague and cholera is marked by diminution, or cessation of all these qualities and actions. Of the effect of this on the change of the tissues we have little evidence, but we see secretion stopped and converted into exudation, which physiology teaches is directly the opposite of vital action; the evolution of animal heat ceases; the veins contract like those of the dead body; the blood returns from the terminal structures in a condition very different from that of health—not coursing freely through the vessels, but slowly, and as if adhering to their coats, and in a half coagulated state; and, lastly, by the application of stimuli, which would produce immediate reaction in the healthy skin, we find it almost impossible to excite these vessels in cholera. The direct conclusion from all this is, that impaired excitability, nervous energy, and vitality of the capillary circulation, is the first and most essential effect which we perceive of the impression of ague or cholera, and that the change produced upon the blood is more probably the secondary effect of the cessation or diminution of those changes which are produced upon it in the capillaries of the lungs, and of the system in health, than in any way attributable to direct influence of the poison on the blood. In the whole class of diseases now under consideration, we shall find evidence of disorder of the sympathetic system in one or more of its vital functions, displayed either in the capillary circulation, the digestive, or in the cerebro-spinal system; but in not one of them is any conclusive evidence to be found of a poison eliminated from the system by the fit, in any way resembling that which is thrown off from the blood in fevers produced by animal poisons of the class exanthemata, nor can we conceive any source of constant and universal irritation to the constitution, such as would result from essentially diseased condition of the blood, to be characterized by intermissions, or to be capable of cure by means addressed to the mere interruption of periodicity. In such a case, on the contrary, we should expect only a continued and persistent action, till the end to be accomplished by the elimination of the poison is attained. Moreover, if it be granted that continued fever is the effect of a constant source of irritation existing in the blood, it would appear to be a corollary to the proposition that intermittent, as opposed to continued reaction, is direct evidence of the absence of a source of irritation in the blood, and produced by means diametrically opposite, which we have fair grounds for concluding to be the absence of that irritability in the very structures which become excited by a source of irritation existing in the blood in continued fever, or by their natural stimulant in health, viz., distension by the *vis a tergo* of the heart*

On these grounds, considering simple ague as the type of the whole class of diseases which we are about to study, we shall proceed to examine its symptoms and the indications for treatment.

SYMPTOMS AND TREATMENT OF INTERMITTENTS.

Intermittent fever has been generally described as consisting of a cold stage, with shivering; a hot or febrile stage; and a stage of perspiration and relaxation, followed by intermission. This description cannot, however, be received as a definition, because of these stages there is only one that is constant,—viz., periodical return of the cold stage, while the febrile and sweating stages are only the consequences of subsequent reaction and relaxation, and sometimes they are altogether absent. But shivering is by no means an essential to the cold stage; on the contrary, in the most dangerous forms of ague, shivering is often absent, as it is in cholera, because the disturbance of the circulation in the cold stage is such as to overpower this symptom.

Shivering may practically be considered not so much a symptom of the impression of cold on the body in health, or of the cold stage of ague, as an evidence that reaction is taking place in the system, and that the heart possesses the power to overcome the obstruction opposed to its action; it is, in fact, the first step of the febrile stage, and in the more malignant forms of ague, is the surest harbinger of recovery, and the best evidence of reaction.

* The above reflections may serve to suggest the question to physiologists,—whether the circulation of the blood by successive pulsations of the heart instead of by a continuous action, may not be a wise provision of nature to avoid the exhaustion of nervous sensibility in the capillaries by continued impression.

In the medical treatment of ague, little is generally attempted in the cold stage beyond giving a stimulant diaphoretic, or in the febrile beyond cooling diluents. It is customary to trust entirely to the means of prolonging and confirming the intermission by the use of antiperiodic medicines. But this routine method of treatment is not applicable in all agues, for these differ materially in the urgency of their symptoms, according to their various types, and the duration of their period of intermission.

Thus, both in quartan and in tertian ague, febrile reaction generally runs so high as to cause this stage to be most dreaded by the patient, and the congestive stage is of comparatively little moment, being accompanied with shivering almost from the first; but in quotidian the case is very different, the fever, where it exists, being slight and of short duration, and both this and the sweating stages often absent or imperceptible, and the interval between the fits is sometimes so short as to be insufficient to restore natural irritability to the system by repose. The congestive or cold stage is, on the other hand, extremely severe, and such as to endanger the vital organs, and even to give rise to the dread that the attack may prove fatal before it reaches the stage of reaction. In such a case, then,—and such it will appear is cholera,—not fever, but the opposite condition, is to be feared, and all our efforts must be directed to obviate or relieve congestion.

There cannot be a doubt that this is the most essential part of cholera, and the great source of danger in congestive ague; we shall, therefore, devote the remaining portion of this lecture to the consideration of the congestive stage in its cause, course, symptoms, and effects, and to the mechanical means of relieving and curing it, whether natural or artificial, reserving what we have to say on the medicinal part of the treatment for a future lecture.

It is customary to date the commencement of a fit of ague from the commencement of shivering, and of cholera from the first purging, but this is an important error, for long before this symptom comes on, a certain shrivelled appearance of the skin may be observed; the expression of the eyes changes; there is a feeling of malaise and confusion in the head; the nails look blue and bloodless, and are marked with a red and white streak, and there is a tendency to yawn, and a feeling of oppression about the heart, accompanied with sighing.

The essential part of ague has begun, perhaps, as much as two hours before the shivering occurs; the blood is gradually forsaking the extremities, and is driven in upon the heart more quickly than it can be sent through the pulmonary circulation, whose capillaries also resist the free transmission of blood; it therefore accumulates in the great veins, so that a great part of that fluid which a short time before was circulating in the extremities, being now rejected by the capillaries, is forced to find room in the venous reservoirs, and great vascular organs of the chest and abdomen, while the arterial system is left comparatively empty.

The consequence of this congested condition of the great veins is the disturbance of the circulation in the thoracic and abdominal viscera, and oppression of the action of the heart. This disturbance of function produces an excitement in the organs themselves (that is, upon and through the sympathetic nerves,) to resist oppression, by increased efforts to preserve life, or what is called reaction. When this effect is felt, the whole frame partakes of the influence, and manifests it by convulsive shivering. The struggle of the powers of life against the disturbed or oppressed action of those organs whose office it is to sustain life continues, till at length the highly-excited powers of the heart and arteries overcome the inertia of the capillary circulation, and the blood once more courses freely through the veins. But this excess of action does not immediately cease with its victory, a period of fever succeeds, till at length, exhausted, the capillary circulation becomes relaxed, perspiration bursts from every pore, the excitement of the heart subsides, and the circulation returns to its natural condition for a time. This period of repose is not, however, permanent; by and by the capillaries again succumb to the effects of renewed impression, the same effects are produced as before, and the same struggle ensues. The duration of the cold fit depends upon the susceptibility of the sympathetic, to be sooner or later roused to perception of the disturbance of the vital functions which is taking place, and on its ability to excite the organs of circulation to more healthy action, for according to this will the struggle be more or less severe and protracted, and in like manner the severity of the congestion and abridgement of the period of intermission will be in proportion to the power of the impression to produce the paralytic condition of the capillary vessels by its agency on their nerves, till the climax is reached in cholera where intermission is either wanting, and consequently fatal, or very imperfect.

If, then, the cold stage commences in disturbed capillary action, and contraction of the veins of the extremities, by which the blood is forced into the interior sinuses of the chest and abdomen, distending the spleen, oppressing the heart's action, and disturbing the circulation and functions of all the viscera, it is evident that to prevent or remove this disordered capillary action before it produces the above effects, will be to prevent or cut short the fit.

If again capillary disturbance have taken place, but blood from the extremities be prevented from reaching the interior in great excess, and from producing more than mere disturbance in the circulation and action of the vital organs, the symptoms of congestion, or the fit, will be prevented, or so far mitigated that reaction will take place with comparative ease.

Or, thirdly, congestion and oppression to the heart having taken place so severely as to prevent reaction from being evinced by shivering, the removal of some part of the blood which is producing it will enable reaction to take place, and this last is the use of bleeding in cholera, as well as in the cold stage of ague. In the cure of ague, therefore, the three intentions we have to fulfil by treatment are—

1st. To prevent disturbance of, or restore natural action to, the capillary circulation.

2nd. To prevent excessive congestion, by anticipation.

3rd. To relieve this if it have taken place.

The first has been accomplished sometimes by producing a sudden general impression on the nervous system,—as for example, by unexpectedly plunging the patient into cold water; but the more usual method is to give those medicines which possess a peculiar power in preventing periodicity, such as arsenic, and quinine, or if we consider their *modus operandi*, we might say those which possess a peculiar tonic effect upon the capillary circulation, or upon the sympathetic nerve in *that* part of its functions, and which, by producing an effect directly opposed to that of malarious poison, act as antidotes to it, in the same manner as diffusible stimulants will oppose the depressing effect of digitalis or aconite on the action of the heart.

The first, then, is chiefly the medicinal part of the treatment, which shall be considered hereafter; the second and third rather mechanical than medicinal, for the second intention is attempted to be fulfilled by the application of tourniquets to the limbs in such a manner as to retain as large a quantity of venous blood in the extremities as possible, but is still better effected by the early use of venesection before the more prominent evidences of congestion have been manifested. The third is, after the congestion has taken place, to draw blood rapidly from both arms, in order to relieve the congestion.

The mechanical treatment of ague by bleeding, therefore resolves itself into this, that if we can bleed after disordered action in the capillaries has commenced, and as yet has only disturbed but not oppressed the action of the heart, but before the great struggle of the system which ensues on established congestion has begun, the abstraction of blood is easy, safe, and effectual in preventing congestion and producing immediate cure; but after SHIVERING has begun bleeding is unnecessary and may be injurious, because it will then disturb the healthy reaction of which this is an indication. If practised after the commencement of shivering, the first effect of bleeding will be to bring back the congestive stage with tendency to collapse, and afterwards to relieve it; but this is done at unnecessary expense of blood, and although generally successful in cutting short the ague, is practically neither so safe nor so effectual as bleeding just before shivering begins, and therefore it is better to delay till the next antecedent period.

When, however, the evidences of extreme congestion exist without shivering, shewing that it is becoming dangerous, and that due reaction is prevented by the mechanical obstruction offered to the heart by excess of blood, bleeding from the veins cannot be had recourse to too promptly, in order to relieve it and the other organs from the pressure. But although in an early stage these are perfectly good and intelligible reasons for bleeding where congestion is severe, the practice is not to be recommended after it has existed for a long time, and the reason is this,—

Experience has proved, that often in cholera, where scarcely any external evidence is given of reaction, or restoration to a more natural condition of the circulation, such restorative action is nevertheless really taking place, and if the powers of life can only support the oppression without utterly failing, for a certain period, the disturbed circulation of the capillaries will by and by cease, the heart be freed from obstruction and the general circulation be more or less restored. Practically, therefore, it is better and safer not to use the lancet if congestion have existed for several hours, lest by bleeding we disturb the natural tendency to recover, so far as to reach a second period of relief at least, if not of reaction; and lest instead of relieving oppression, we should thereby produce syncope. Under such circumstances it is more adviseable to trust to medicine and to nature, until the 18th or 20th hour in quotidian disease, or till an hour or two before the next anticipated fit in other forms, shall afford us a safer and more advantageous opportunity of pursuing the same practice with a view to arrest the congestion in its renewed accession. The case, however, is very different when early called to a patient in whom this condition has existed but a short time, and when there is reason to believe the heart to be in full possession of its energies and only in want of mechanical relief to enable it to resume its powers. In such circumstances there is not only no danger from bleeding, but its effect is little short of miraculous, and in the course of a few minutes, the patient arises from a bed of death and torture, to the full enjoyment of life and health.

In a case like this, no mistake is so fatal as delay, which is unfortunately the most general one, for here the timid practitioner fears to bleed when he can hardly feel the pulse; he hesitates and waits until he observes it rise a little, and then acting on the rule, rather than on the reason of the practice, he opens a vein, cuts short the feeble attempt at reaction, and kills his patient in the attempt to cure him. Some have even carried culpable ignorance of the intention of bleeding in cholera so far, as failing to obtain blood from a vein, to open an artery, little thinking how much reduced is the quantity of properly arterialized blood that amid the disorder reaches the left side of the heart, and that upon the capability of that little to sustain life through the struggle depends the life itself. By taking arterial blood he takes the life of his patient, produces syncope, and having removed the feeble resistance to death which still existed, his patient sinks at once and invariably into complete collapse. Of this fact there is no want of examples on record. Be assured that the rising of the pulse after it had been lower, in cholera, as in congestive ague, is positive reason against bleeding, and the best evidence that the constitution possesses the power to carry the patient over that days' attack, to enable him to reach a second, if only let alone, and not worried to death with over-treatment.

When, however, we decline to bleed after the patient has been labouring under severe congestion for five or six hours, we must search for the practical reasons against doing so, in the effects produced by bleeding in the hot stage of intermittent. This is a subject on which I can speak from sad experience, and one on which unintentional evidence is borne by many cases

reported in various works on cholera, where bleeding has been practised in a late, but yet too early, period of the attack.

In ague, when the period of congestion is over, and the febrile stage marks the progress towards a return to natural action, but where the impression which produced the cold stage is as yet only partially recovered from, it is evident, if the theory be correct, that the effect will as readily be renewed as that of light upon the half-dazed eye, which, having been fixed on an object till insensibility is produced, and only half restored to its sensation by removal, is again subjected to the impression, without sufficient interval fully to regain its powers, it becomes almost immediately re-affected as before, and insensibility is nearly instantaneous. So it is with bleeding in the hot stage of ague; syncope and return of the congestion are the immediate consequence; or in less severe cases, or later in the hot fit, the intermittent is in danger of being converted into remittent fever of a low, irritative, and dangerous character. Much more might be urged on this subject to show that, independently of the above considerations, that period which immediately succeeds to a long and exhausting struggle of the heart and arteries is not the most favourable time to expect a greatly increased effort, but that on the contrary, *when* the tone of the exhausted vessels, now long accustomed to an overcharge of blood, has become impaired, syncope should be a more probable consequence of venesection than relief and reaction.

If then we have reason to believe that there is a natural tendency to recover from this condition, and to dread and expect its renewal at a certain future period, we must be exceedingly careful not to run into the dangers we have indicated by mistimed bleeding, but rather trust for a time to medicine alone, and await that more favourable period, which, with proper care, will arrive with certainty in by far the greater proportion of cases of congestive ague, and also, I feel assured, from my own observation, in cholera.

We shall have occasion again to return to this subject, but were I called on to give a rule for bleeding in the congestive stage, it would be to bleed early and boldly in the first, or even the second, hour, but no later, till the eighteenth or twentieth, after its first manifestation, when the same rule will again apply after the twenty-fourth.

The above remarks have been addressed chiefly to the consideration of the cold stage of intermittent fever, and their application to cholera has been only incidental; nevertheless I have stated, that I believe cholera to partake also of this character,—viz., a tendency to intermission, however slight and imperfect. I am unwilling to state a fact of this importance on my own observation only, and, prefer to rest the argument on the near relation of cholera to quotidian ague, and on its connection with diseases of an intermitting character, with which it was associated in its first onset in Persia, in 1842-3. This will form the next part of our enquiry. For the present I shall content myself with stating that the perusal of cases by a great variety of authors, has not tended to change this opinion; and I conceive, that if read in the same spirit with which I perused them, this will also become your opinion of the disease, both as it has appeared elsewhere, and as it will probably appear here. In the usual form of cholera, I must allow that the symptoms of this condition are very slight indeed, and I cannot expect them to be conclusive with most, because only to be recognized, if recognized at all, on being sought for with the desire to find them, which undoubtedly is not good evidence. The obvious and external signs of its existence, merely amount to this,—that in most cases of cholera, not rapidly fatal, if visited about the eighteenth or twentieth hours after the commencement, the patient will be found lying in a sort of lethargic condition, apparently more sunk and more resigned than he had been for several hours before; but on examining the action of the heart with the stethoscope, you find it more natural, and less excited;—you find the warmth a little more extended on the chest, and the patient rather sulky than insensible. If, finding him in this condition, you sit down by him, and watch what takes place, you observe this apparent lethargy cease, he again becomes agitated, throws off the bed-clothes that he had latterly permitted to remain upon him, the action of the heart again becomes tumultuous, and the previous signs of suffering are increased. This certainly is but small evidence of intermission, nevertheless it is some, and considering it as such, the efficacy of bleeding in this stage of repose, or just as the agitation is beginning, has been such in my own practice, as to my mind, to corroborate the opinion; whereas the result of the practice of bleeding, as the pulse begins to rise very slightly previous to the period when this kind of repose might be expected, (as I have seen practised by others, and which you will find recorded in many published cases,) is very much the reverse. I can only endeavour to reason on this subject, which must be left to the general experience of others to decide. I am satisfied, however, that as far as my own has gone, the rule I would attempt to impress, with regard to the most favourable times for bleeding, is correct.

There are, however, other objections to this belief, as, for instance:—Why should not a man recovered from cholera be subject to continued daily accessions? This I confess myself unable to explain, but such is the case with many other diseases, such as ague cured by bleeding; and it is not always the case in cholera, though the character of the accession may differ. It would be too much to attempt to explain everything of what is confessedly so obscure, that even the smallest contribution to its history is looked for with anxiety; but while upon this subject, I may merely mention one point of observation, which, if more extended experience tend to confirm it, may aid in explaining the natural mode of cure in cholera. This is, that in all forms of quotidian ague with which I am acquainted, there appears a marked tendency to run a course of three days; and you will find many recorded cases of cholera which will bear this interpretation, where, after three accessions, or, if you please, three days' continuance, of the symptoms of cholera, the coldness and

purging cease. Thus, a man has purging one day and gets better; next day he is attacked with algide cholera, he struggles through this, and there is imperfect attempt at reaction, but the purging, cramps, and coldness again become severe on the third; if this day's accession be not fatal, he goes on into the stage of consecutive fever on the fourth day. Many cases appear to confirm this view, and many to oppose it, as may very naturally be expected, for it is by no means easy to distinguish the effects of the very active treatment pursued, from those of a very active disease.

In treating of cholera, one of the greatest difficulties arises from its unfortunate and most inappropriate name, which would seem to point to the diarrhœa and disturbance of the bowels as the essential part of the disease; and if we look merely to popular opinion, and to that countenanced by documents issued by authority, it would appear as if no room were left for doubt upon this subject, and that the great matter to be attended to in the cure, is the arrest of diarrhœa, as if that were an invariable symptom, and the most imminent source of danger. It is undoubtedly very right in popular treatises and directions, to fix public attention upon this symptom, because in the epidemics best known, this has been one of the most frequent early effects, and it is well that it should be looked upon as most dangerous, and as a good reason for applying for medical aid before worse follows; but it does not become the professors of medicine, as a science, to adopt such an opinion without examination. We have endeavoured to shew, that, according to particular circumstances, of which we are ignorant, a very considerable derangement of a part may exist without that general disturbance of the whole capillary system, which we observe in the cold stage of ague or a confirmed attack of cholera,—that exudation may at one time take place from the bowels; at another into the cellular texture of the body generally or locally; at another, that this peculiar condition may chiefly affect the cerebral system, with extremely little or no evidence of the capillary circulation of the extremities partaking of the influence,—that in fact, the force of the disease may at one time be directed on one class of organs, at another on another, just as we witness the fever of one year to be attended with ulceration of the ileum,—of another in the colon,—of another with pneumonia,—and yet, another with cerebral affection, &c. So when we come to consider the different modes in which the system may be and is affected by the impression of a choleric influence, we shall find it producing the same effect on the general capillary circulation, and the same consequent congestion of the interior organs; but we shall observe that this oppression does not always seek the same mode of relief, although the end attained is still the same—viz., diminished quantity of the venous blood; and that it does not uniformly expend its force by exudation into the intestines, which is the form we are most familiar with, but that in like manner exudation will take place into the serous tissues and from the skin. These are my reasons for not insisting so much as is usual on the diarrhœa of cholera. Even those authors who lay most stress on this symptom, constantly inform us that the most malignant cases are those in which there is neither vomiting nor purging; such, for instance, as those extreme cases which almost always occur on the first arrival of cholera in a district, where the patient is seized with sudden pain in the epigastrium and expires in a few minutes, with the word "water" on his lips, but without either vomiting or purging,—that is to say, without the more ordinary means of relief to the congestion having come to the aid of the vital powers. Thus, Mr. Parkes, who is one of our most recent authorities in cholera, but whose views are very different from those now advocated, says,—"There is no one who has seen much of cholera who does not know that, exclusive of the mildest forms of the disease, a case with little vomiting and purging is more malignant and more rapidly fatal than one in which these are prominent symptoms;" in other words, this might be expressed, that where natural relief to the congestion does not take place, the congestion proves more fatal. Premising then, that we do not look upon purging as essential to cholera, but only as the most common mode of relief to the circulation, and that it takes place earlier or later in the stage of congestion, according to the peculiar tendency of the epidemic and condition of the individual attacked, we shall trace the ordinary course of the first stage of cholera up to this point, passing over those cases of diarrhœa in which it would appear that the relaxed condition of the enteric vessels proceeds so *pari passu* with the general tendency to congestion, as to prevent any serious amount of internal congestion from occurring, such as is very frequent in the first day's attack of cholera, and from which many recover without passing into the algide stage.

When a man is attacked with cholera there is something in his appearance which another, who has had experience, may recognize, even before the patient himself is aware of it; there is a sunken clay-coloured cast in his features; he looks stupid; perhaps has slight dimness of vision, or dulness of hearing; his hands look shrivelled, the nails blue, and the veins on the back of the hand are dark and contracted, like lines traced with ink upon the skin; it is cold and damp to the touch; if you look at the tongue you find it clean, pale, and watery, as if macerated till deprived of blood, and the conjunctiva is bloodless. He, perhaps, now feels a sudden but slight pain dart occasionally through the left breast and arm, and if you press upon the epigastrium, especially over the spleen, he complains of pain; he has then sudden call to stool, perhaps vomiting, or according to the character or type of the disease, there may be intense pain and sense of burning in the stomach, &c. Let it suffice for the present to trace the course of these symptoms up to this point.

The shrunken condition of the skin indicates the state of the peripheral capillary circulation, and when the minute vessels reject their blood, it accumulates in the vena cava, overcharges the right auricle and ventricle, and interferes with their action; it distends the spleen to its utmost capacity as the reservoir provided by nature to relieve the circulation

when oppressed by too great accumulation of venous blood. Hence pain referable to the heart, and that produced by pressure on the spleen; the pulmonary capillaries partake of the inaction, and resist the passage of blood through them, the accumulation of blood continues from the exterior, and the inferior cava is so distended that it is impossible for blood to enter it by the renal veins; the circulation of the kidneys being thus suspended, their secretion is arrested, hence suppression of urine. Still blood accumulates which cannot revert through the well-valved veins of the extremities, and it must go somewhere. The portal circulation already oppressed, so as to prevent the secretion of bile, now yields still further, and the blood is forced back in a retrograde course along the mesenteric veins till their minutest terminations on the villous coat of the intestines are injected as with a syringe, and their natural action is at an end; a little more blood suffices to make the watery particles filter through the membrane, carrying with it the mucous epithelium, which gives that peculiar character to the cholera evacuation that has been so aptly described as the rice-water purging. No sooner, however, has a large evacuation of this kind been produced, than immediate relief is, in the great majority of cases, experienced by the heart which had been struggling with the load of blood that oppressed it; the same effect is produced directly, which we endeavour to produce indirectly by opening the external veins, and the heart is thereby enabled to overcome the resistance of the capillaries, (already as I think disposed to relax,) thus a natural cure is often effected which the well-timed administration of a stimulant may hasten and confirm. If, however, this first evacuation of the fluid particles of the blood does not suffice to give relief, the same effect of increased congestion and attempted relief by purging takes place again and again, till the power of reaction ceases, and the patient dies in the stage of collapse. Perhaps, however, he is more fortunate, and though ineffectual to produce complete relief, and restore the power of the circulation, these frequent drainings of the interior veins may suffice so far to relieve him, that the congestion does not destroy life, and there may yet be sufficient blood pass through the pulmonary capillaries to maintain life through this emergency, and so far to restore more natural action, as to permit of something approaching to repose to the patient from his sufferings, and partial return of the organs to their natural functions. This would doubtless proceed gradually to reaction, and sometimes does, when there is no fresh accession of capillary disturbance to renew the congestion, and the consequence is the low form of fever alluded to; but unfortunately there appears to be a tendency to relapse, which my observation leads me to believe occurs just twenty-four hours after the first commencement of capillary disturbance, the weakened powers now more readily yield to the oppression, and about the twenty-sixth or twenty-eighth hour is one of the most frequent periods of death in those who have escaped during the first eight hours. After this the period of death must be uncertain. I find that Mr. Parkes gives the average period of death in forty-one cases as twenty-seven and a half hours from the commencement.

Having now considered the subject of congestion at great length,—first, in its probable origin; secondly, in the effects on the peripheral circulation; thirdly, in the effects and symptoms of the distension of the thoracic and abdominal veins and viscera; and fourthly, the artificial and natural means of mechanical relief and cure, we have now, I think, only to consider the symptoms of recovery and of death in cholera, and of the *post-mortem* appearances, before we proceed to the medical part of the treatment.

The symptoms of the disease, if traced in their natural order of succession, are as follow, and those of recovery these reversed:—

1st. Constriction and bloodlessness of the capillaries—of the skin first, and afterwards of other organs, with coldness of surface.

2nd. Oppression of the heart and pain in the epigastrium.

3rd. Suppression of urine.

4th. Suppression of bile.

5th. Vomiting and purging—one or both, or neither.

6th. Muscular spasms in connection with spasmodically contracted colon, and with the state of the bowels.

7th. Especially where the purging has been absent or scanty, tetanic convulsion of the whole body, from the influence which at first was confined to the circulating system, proceeding onwards to attack the nervous system, as the circulation of arterial blood ceases.

8th. Death by mere cessation of action of the heart, &c., or by affection of the nervous system in tetanus, or both combined.

9th. Returning warmth to the skin after death, which in life had been icy cold. This, as far as my own experience goes, is always the case, commencing in the extremities, but, perhaps, does not occur so remarkably when purging has been very long continued, and the disease much prolonged. Of this I cannot speak with certainty. Partial return of warmth to an isolated part of the body is mentioned by several authors as a sign of extreme malignancy in the attack, and a certain forerunner of death. In all the cases where I have witnessed death from a rapid attack of cholera, whether in this country or in Persia, where there was either no purging, or where it had soon ceased, I observed the feet begin to get warm some minutes before death, and sometimes the warmth spread even above the knee, while the thighs and body remained cold, and the patient yet lived. This I look upon as a sign of death, beginning in the extremities, and I have invariably observed, that after the occurrence of this symptom, the least interference was apt to induce tetanic convulsion. I have twice attempted to draw blood under these circumstances, but am now convinced that this symptom always is a sign of death, whether the patient appear to live or not, and I feel much inclined to consider that hope still exists, so long as this symptom is absent. We shall again allude to the subject in speaking of the treatment by heat and cold.

Post-mortem spasms in the muscles not unfrequently

occur, even some hours after death. These do not appear to be the mere effect of relaxation of spasmodically contracted muscles, but rather resemble the jerking spasms produced by galvanism on an animal recently killed, and are probably intimately connected with the cause of warmth returning to the corpse, which in life had felt icy cold, and afford some reason to believe that the condition of the capillaries produced in life by cholera is not a mere cessation of vitality in them, as we have considered it; for the cold, where purging is scanty, exceeds that of any dead body, insomuch as to suggest a question, whether the chemical or electrical actions in the capillaries which belong to health may not be not only impaired, but actually reversed in the disease, and heat absorbed instead of being evolved.

On opening the body after death, the appearances are exactly such as we should expect from the symptoms. The right side of the heart is found gorged and dilated, the dilatation and softness of the coats being greater as the case has been more protracted. The superior and inferior cavæ, and all their larger branches are loaded with dark, tarry, half-coagulated blood. The minute vessels of the lungs are empty, and the parenchyma often shrivelled and contracted, being pale on the surface, while the pulmonary artery is quite full of blood. The left side of the heart is contracted, and either empty or contains firm coagula, indicating a greater amount of life in the arterial than venous blood, which forms no solid coagulum; and the contraction of its auricle and ventricle a less amount of exhaustion of the muscular fibre in the left than on the right side of the heart, which is flabby and distended. The amount of congestion of the portal circulation, &c., is always considerable in the large vessels, but the smaller ones are more pale and bloodless in cases in which there has been much exudation. The gall-bladder generally contains bile. The spleen is commonly congested, but sometimes found empty, which is, probably, a *post-mortem* effect of its peculiarly elastic structure; when death takes place from consecutive fever, however, it is soft and friable, an almost invariable condition in death from malarious poisoning by tropical fever, &c. The intestines present a peculiar appearance, the colon much contracted and empty, the small intestines containing fluid similar to that passed in life, mixed with a denser material, probably the fibrin and albumen in peculiar chemical combination from which the more fluid part of the blood had been drained off, the submucous coat is distended in different places with the same material, sometimes mixed with broken-down red globules. The kidney is nearly normal, and the bladder contracted; the brain seldom presents anything peculiar. These appearances require no comment beyond that which has preceded their description in relation to the symptoms.

It would appear, then, that congestion and oppression to the circulation is always the cause of death, and that congestion is a consequence of disordered capillary circulation. We have sufficiently discussed the modes, both natural and artificial, of relieving this congestion, but as yet we have left the means of removing its *cause* in the capillary circulation altogether unconsidered, although it is perfectly evident that this must be the main object of medical treatment. The patient is cold, nothing can be more natural than to try to warm him, and the circulation being nearly at a stand, what is more natural than to rouse it with a stimulant? But then he is cold only to our sensations, not to his own; he is burning and suffocating, and cannot bear even clothing, much less external heat; he is craving for ice and cold water, and the hot stimulant draught which we force upon him is torture; he is vomiting, yet anxious to drink.

Are we then to treat him according to our sensations or to his?—to torture him, or indulge cravings that appear to us so opposite to what his condition requires?—or are we to disregard alike his sensations and our own impressions, and seek for the means of removing the cause of this anomalous condition?

These are questions of which we shall defer the consideration till our next meeting.

CASE OF FUNGOID DISEASE OF THE PANCREAS.

By George Norman, Esq., F.R.C.S., Senior Surgeon to the Bath United Hospital.

(Read at the Quarterly Meeting of the Bath and Bristol Branch of the Provincial Medical and Surgical Association, September, 1848.)

A gentleman, aged 31, consulted me in the beginning of July, 1848, for an uneasy feeling after eating, and a degree of nausea, which he had experienced during the previous fortnight, having always before enjoyed good health. There was nothing to induce a belief that it was more than a temporary derangement of the stomach, but in a few days after, the tunica conjunctiva became yellow, and in less than a week he had complete jaundice. There was no enlargement or fulness about the region of the liver, nor any pain felt on pressure. An active purgative plan did not diminish the jaundice, and the evacuations exhibited a total absence of bile, and, excepting on two or three occasions, there was never afterwards any evidence of the bile getting into the alimentary canal.

On the 1st of Augst, I again made a careful examination of the abdomen; there was still no evidence of disease of the liver, but by pressing very hard on the region of the stomach, I could feel an oblong tumour, crossing the spine, hard, deep-seated, immovable, and not painful on pressure; its situation was that of the pancreas, but it was difficult to believe that that organ could be felt in a person not emaciated.

He was put on a course of mercury, and his bowels kept relaxed by taraxacum. During the whole of this time he never complained of pain; his appetite was good, and his nights very tolerable. The mercury was continued till the gums became tender, but without any mitigation of the jaundice, and the tumour, when again examined, was found to have increased in size. On the 13th of August, Dr. Davies saw the case with me, and in examining the abdomen, a hardness and

fulness were found below the ribs in the right side, and it appeared to us that the liver was enlarged and extended some way below the rib. On the 16th, on examining, we found what appeared to us to be the edge of the liver, extended as low as the umbilicus, and that there was also enlargement and hardness in the situation of the left lobe of the liver. The day after this he was suddenly seized with violent pain in the left side, extending round to the back, which continued the whole night, and part of the next day, when it ceased, and was no more complained of. On the 19th he vomited his food, and from that time he scarcely kept anything on his stomach. On the 20th, Dr. Packman, of London, saw him with Dr. Davies and myself, and he considered with us, that there was great enlargement of the liver, but he thought there was also disease of the pylorus. On the 22nd the patient died.

The body was examined, and from four to five pints of fluid, deeply tinged with bile, were found in the abdomen. A large tumour was discovered stretching across the spine, extending under the ribs on the right side, and downwards as low as the umbilicus. To this tumour the transverse arch of the colon adhered, the coats of which were indurated, and partook of the nature of the tumour. The pyloric portion of the stomach was pushed upwards out of its natural situation by the tumour, and the liver also was forced up higher into the chest than natural. The tumour was the pancreas greatly enlarged, and indurated in nodules of a true scirrhous character. Embedded in its substance was the termination, and a good portion of the common duct of the liver, quite impervious, from the point where it entered the tumour. The hepatic duct was so distended with dark-coloured bile, that it was more than an inch in diameter; the gall-bladder was also distended to its utmost with dark-coloured bile. Attached to the pancreas, and forming a considerable portion of the tumour, was a large mass of the soft broken-down substance denominated fungus hæmatodes, occupying principally the left hypochondrium. Some of the vessels in this substance had given way, for there was a large coagulum of blood behind the peritoneum, which had no doubt been the cause of the violent pain felt in the left side and in the back, three or four days before death, and the cause of the rapid exhaustion of strength. In the mesentery were masses of considerable size of soft medullary matter; the liver was harder and larger than natural, but otherwise exhibited no evidence of disease.

INTERNAL USE OF CHLOROFORM IN DIARRHŒA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I imagine the only means of arriving at anything like a satisfactory conclusion as to the effect of any new mode of treatment is by each recording his experience of it, that by an accumulation of facts we may be enabled to establish such practice. In the present instance I lay no claim whatever to originality as to the mode of treatment, (as indeed the readers of your Journal will be aware, for it was in consequence of having seen two cases recorded in it, by Mr. Brady and Mr. Stedman, that induced me to try chloroform in the following case):—

I was requested to see an old woman, aged 78, who had been suffering from excessive diarrhœa and sickness for four days, and could keep down nothing but a little brandy. She had had a little cramp. As I was not able to see her immediately, I sent a powder containing calomel, opium, capsicum powder, and Pulv. Cinn. Co., which was rejected instantly. When I saw her two or three hours afterwards, I found her exhausted to the last degree, the bowels were acting every half hour, and the excretions of a frothy serous nature, with a perfect absence of bile, the sickness was incessant, the urine scanty and with a very copious deposit. In this state of things it was evident that unless the symptoms abated she could not last long, and I therefore resolved to try chloroform as a stimulant, and calomel upon the principle so ably advocated by Dr. Searle. I accordingly gave her ten minims of chloroform, with half a drachm of Tinct. Zinzib. and two drachms of Aq. Cinn., in a little brandy and water, at the same time putting on the tongue, a powder containing two grains of calomel, and three of campound tragacanth powder, which latter was repeated twice at intervals of two hours, and the chloroform draught again at bed-time. The diarrhœa and sickness both ceased after the first draught and powder. She passed a comfortable night and kept down some toast, &c. On the following morning I found her much better, the pulse firmer and a nice warmth of surface; there was no action on the bowels or sickness during the whole day. I gave her two more draughts of chloroform and two calomel powders in the course of the day; she had again a very comfortable night, had two natural and healthy motions on the following morning, and the urine was perfectly clear and sufficient in quantity. They omitted sending me a report on the following morning, as they were instructed to do, and consequently she had no medicine to take until the afternoon, when I saw her and found her much exhausted with a feeling of nausea. I ordered the chloroform draught to be repeated, which relieved her instantly, (or to use the expression of her nurse,) "seemed to put new life into her." She passed a very comfortable night, kept down everything she took, and the secretions were quite healthy and regular. She continues taking a mixture, containing small doses of chloroform, with Tinct. Cardamomi Co., and Tinctura Zinzib., and is now fast convalescing, and can take meat and porter in small quantities.

I should mention, that before I saw her, she had been taking, by the advice of a lady, laudanum in brandy, several times, but without the slightest effect, although it was retained on the stomach; I think, therefore, we may fairly attribute the abatement of the symptoms to the combined action of the chloroform and calomel. I can also state, that I have since tried the same remedies, under similar circumstances, with equally satisfactory results.

I remain Sir,

Yours faithfully,

S. GEORGE SLOMAN.

Farnham, November 18, 1848.

CHLOROFORM IN DISLOCATIONS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The idea of using chloroform in cases of dislocation has, I think, been several times suggested in the Journal, and, if I am not mistaken, instances of its successful application have been reported, though I am not able immediately to refer to them. But this need not prevent me from giving the following brief account of a case which has lately occurred to me at the Northampton Infirmary, in which the efficacy of this agent was certainly wery signally and satisfactorily marked.

Thos. Fisher, aged 28, from the parish of Hargrave, near Thrapstone, 21 miles from Northampton, was brought as a patient on Saturday, the 7th instant, having a dislocation of his left hip into the ischiatic notch. He was accompanied by a highly intelligent and practical surgeon, who had been called to him on the occurrence of this accident at half past six o'clock, the preceding evening, and who, on ascertaining the nature of the case, had immediately adopted the usual mode of treatment, keeping up a very powerful extension by means of double pulleys for nearly three hours, but without success. He consequently brought his patient to this infirmary, where the same means were again had recourse to, about twenty-two hours after the accident, together with a copious bleeding from the arm, and tartar emetic in doses of one grain every ten minutes, to the extent of eight grains. No faintness nor sickness were produced. The force of extension was carried to an extreme degree, and it was persevered in for an hour and a half, but without any success. At this period, a part of the apparatus having become rather faulty, the patient being a good deal fatigued, and the hour of the day being late and inconvenient, it was thought advisable to postpone further treatment till the next morning, with the intention of then having recourse to chloroform.

On this occasion, Sunday, October 8th, about forty hours after the accident, having duly arranged the apparatus, chloroform was administered on a pocket handkerchief. Its specific effects were produced in a very short time, when the extension was begun, and in ten minutes from the commencement of the inhalation the reduction of the bone took place, with a very distinct and audible sound; the patient having been entirely spared from all the pain and distress which he had suffered on each of the two preceding operations. The case went on in all respects satisfactorily, and I cannot but think it probable that chloroform may be found more extensively valuable and more unexceptionable in the treatment of dislocations, than even for any of those many other cases in which it is so beneficially made use of. I am induced to take this opportunity of referring to the very great advantage of a "click wheel," attached to the rope of the pulley, concerning which I made a short communication to you two or three years ago. The perfect facility with which any degree of extension may be accomplished, the safe and gradual mode of increasing the stretch, and steadily fixing it for any length of time, without occupying the attention or injuring the hands of the assistants, are important points in the treatment of dislocation, and the cost of the wheel is but a few shillings.

I am, Sir, your obedient servant,

H. TERRY, F.R.C.S.,

Surgeon to the Infirmary.

Northampton, Oct. 31, 1848.

ON THE NECESSITY OF EMPLOYING THE CHLOROFORM IN A STATE OF PURITY.

By H. IMLACH, MD., Liverpool.

Several cases and various letters, published in our weekly medical periodicals, compel one to believe that the administration of chloroform by inhalation, is not found, by many English practitioners, to be so entirely free from unpleasant consequences, nor so invariably followed by full anæsthesia, as our Edinburgh friends have found it, ever since it was introduced by Dr. Simpson, in November last. The cause of this difference I believe to be twofold,—first, the purity of the drug; and, second, the mode of using it. Although both of these matters have been most particularly insisted on by Dr. Simpson, in his various reports upon chloroform; and although Dr. Letheby, in a lecture recorded in the *Lancet*, has well pointed out the chemical tests whereby we may detect the more usual adulterations, still the fact remains, that properly purified chloroform is seldom to be found in the shops of even the most respectable druggists. Patients who have inhaled this common chloroform, are frequently much distressed with cough during its inhalation, by vomiting and faintness, and subsequently by headache and prostration during the remainder of the day. Some also complain of a sense of fulness and heat remaining in the chest for hours after they have ceased to respire it. Practitioners object to its use, because spasms, screams, and struggling interfere with the progress of operations; and several have also reported, that not only have their patients noses and lips been blistered by the chloroform, but that the handkerchiefs on which it has been poured have been injured in their texture and colour by it.

Chloroform has been manufactured in this town from naphtha, or pyro-acetic spirit, and great attention has been given to the purification of it, but, in spite of all washing and re-distillation, it retains something of the peculiar disagreeable smell of naphtha, probably from some of the more volatile empyreumatic matters coming over unchanged during the first distillation. This chloroform is not pleasant to inhale, but I have not seen any bad effects arise from its use.

Every other variety of chloroform I have procured here has contained somewhat of free chlorine, which attaches itself to the handkerchief, and may easily be recognized by pouring a little of the chloroform upon the palms of the hands, allowing it to evaporate, and then the smell immediately attests the presence of this poisonous gas. I have been informed that chloroform has also been sold by very respectable persons in

London, so impregnated with muriatic acid, as instantly to redden litmus paper, and to be almost irrespirable from the coughing which it excites. Such being the case, we cannot impute to *pure* chloroform those dangerous or unpleasant symptoms which are now and then attributed to the free use of this remedy, and which are duly reported to warn the public from believing that "physiological pain" can be escaped with impunity.

It would be waste of time and space to repeat the arguments which have already been so fully adduced by Dr. Simpson and others, to shew that "physiological pain" is philological nonsense; and I am satisfied that no one *sanæ mentis* now believes that it is more sinful to escape the pains of child-birth by means of chloroform, than to escape from toothache by the extraction of the offending member, or by applying to it creasote or tobacco. My present object is chiefly to draw the attention of the profession to the necessity of not being contented with the ordinary chloroform of commerce, but to insist that more care and attention be bestowed upon its preparation by every person who manufactures it.

While conversing upon this subject with a friend, some time ago, he urged that there were as careful druggists and as good chemists in Liverpool as in Edinburgh. I most thoroughly agreed with him as to the honesty of our local manufacturers, who bestow their best attention on this matter; but still the fact remains, that they are not successful in their endeavours, and the chloroform is not sufficiently pure for use; I have therefore been in the habit of getting it sent to me from Messrs. Duncan and Flockhart, of Edinburgh, and shall not use any that is less pure than theirs. Three weeks since I was called in consultation upon a difficult case of midwifery. My friend who was in attendance, had been administering chloroform for several hours to the lady, but as his store was exhausted, the handkerchief was replenished from the bottle of chloroform I carried with me. The lady subsequently assured me that while using the first chloroform she was quite conscious of a very disagreeable heat in the chest, which, however, disappeared entirely as soon as she commenced inhaling the chloroform I had brought. The first was manufactured in Liverpool, by one of our most respectable druggists, and the second by Duncan and Flockhart, of Edinburgh.

The proper mode of administering the vapour from a pocket handkerchief, which is the only good instrument for the purpose, the dose of chloroform which must be measured, not by drops nor by drachms, but by the effect produced upon the system of the patient, and the perfect quiet and stillness which must be observed by all within the room during its application, have been already so fully insisted on by Dr. Simpson, and by my brother in the *Edinburgh Monthly Medical Journal*, that I can merely add, that, if after reading these directions and attending carefully to them, any person fails in producing the desired anæsthetic effect, he must lay the blame upon his own *gaucherie*, and take the first opportunity of seeing it administered by those who are more conversant with its use. Dr. Clay, of Manchester, and others, have not hesitated to state that they were unsuccessful in using it, till they witnessed its administration by Dr. Simpson, in Edinburgh.

On Monday last I had an opportunity of giving chloroform to a parturient woman, who, at the time of her accouchement was labouring under a somewhat severe attack of asthma. Three or four months ago I relieved, in a very short time, this patient from extreme dyspnœa, by making her inhale a few drops of chloroform, and by giving her at the same time a good strong dose of it rubbed up with mucilage. At her confinement, therefore, although earnestly dissuaded by her mother and her nurse, she was glad to take advantage of the chloroform I had promised her, and she not only escaped, for more than two hours, the anguish of labour pains, but breathed quietly and pleasantly, without any of the wheezing, which was loud both before and after the state of anæsthesia. The case has since then progressed as well as possible.

I am sorry I have it not in my power to state what effect will follow its use in cases of heart disease. I do not believe that it had any effect whatever in the case of the late Mr. Barber, of London, who died without ever having come under the influence of chloroform, either pure or impure; nor do I think that unpleasant symptoms are likely to result from its use in similar cases. Last year I prescribed, with very great success, the inhalation of æther vapour to a poor man who was at the time dying from great dilatation of the heart. Effusion had taken place largely into the thorax, abdomen, and general cellular tissue of the body. No medicine gave him any relief from orthopnœa, or from the severe occasional attacks of pain which he called spasms of the heart, and which were often followed by stoppage, for a few moments, of the heart's action. But the inhalation of æther from his pocket-handkerchief mitigated during the last six weeks of his life, his sufferings, and frequently enabled him to enjoy two or three hours of comfortable sleep in bed. According to the pre-conceived notions of some persons, such treatment ought to have killed this patient at once, but for six weeks he was very grateful for the relief he always experienced when he used the æther.

There are some few operations in which it is not convenient to use chloroform; for example, in slow and difficult dissections about the mouth and fauces, in which it is impossible to prevent the blood from trickling down the throat, and suffocating the patient, as the brandy-and-water did the unfortunate girl at Newcastle, and in cases in which some effort is necessary on the part of the patient. Thus, in operating for internal hæmorrhoids, the tumour generally requires to be seized before the chloroform is given; and when the internal rectus muscle of the eye requires to be cut for the cure of squinting, I have seen much time lost while waiting for perfect consciousness on the part of the patient to show whether the whole of the muscle has been divided or not.

These are trifling exceptions, however, to the infinite number of painful operations which are daily perpetrated upon suffering humanity, and I have little doubt that philanthropical ingenuity will soon devise such aids, as will for ever obviate the necessity of the surgeon

or accoucheur ever inflicting or witnessing a moment's pain, while pursuing his blessed work of saving human life, and of relieving those many ills that flesh is heir to.

61, Chatham Street, Liverpool.
November 3, 1848.

SHORT NOTES ON THE OPINIONS AND PRACTICE OF THE LATE JOHN PEARSON, ESQ., F.R.S., ON SYPHILITIC DISEASE.*

By W. S. Oke, M.D., Physician to the Royal South Hants Infirmary.

Ischuria Vesicalis, from Mechanical Causes in the Bladder and Ureters.—This species may be caused—firstly, by the passage of large stones through the ureters. These sometimes produce such distension of the canals that they lose their obliquity of insertion into the bladder, and allow the urine to regurgitate into them. Such patients usually complain of a sense of weight and uneasiness about the loins, together with the symptoms of vesical irritation. After death the bladder is found to be small, and perhaps not above half its natural size, whilst the ureters and pelves of the kidneys are much enlarged and dilated. The cure must be attempted upon general principles; but there is little to be done in such cases. [Many years ago, the late Mr. Corfe, a highly respectable practitioner of this town, shewed me a box containing at least one ounce of renal calculi, of a pale colour, and the size of large peas, which had been passed from time to time by an elderly man, whilst taking the "Haerlem drops," which is a balsam of turpentine. This medicine, I suppose, by increasing the secretion of urine, washed the calculi from the pelves of the kidneys, and not being too large to pass the urethra, they found their way out of the body. Terebinthinate medicines are well adapted, and will probably be found efficacious, for the expulsion of retained calculi, which form in the pelves of the kidneys, from an atonic condition of their membranes.]

Secondly, by vesical calculi. The effects of calculi in the bladder, being well-known, will not be enlarged upon here. There are instances where the stone has adhered to the bladder, and the bladder has contracted adhesions to the abdomen; so that an abscess has formed, and the stone has been discharged above the pubes.

Thirdly, from excrescences. These occasionally form in the orifices of the ureters or in the neck of the bladder, causing either ischuria or dysuria. The urine will be loaded with mucus or a purulent fluid, and the symptoms will be very similar to those of stone—so much so, that the two diseases are easily confounded, before the introduction of an exploring instrument to ascertain the true character of the case. The introduction of a sound into the bladder may lacerate the excrescence and give rise to a fatal hæmorrhage.

Ischuria vesicalis may arise—secondly, from causes contiguous to the cavity of the bladder. Firstly, from enlargements of the prostate grand.

When the size of the prostate is much augmented, it materially affects the exit of the urine. The disease frequently begins by increased sensibility of the gland and pain in the perineum; but such symptoms are so equivocal, that it is often difficult to recognize the disease by them; indeed the complaint may continue many years without any particular enlargement or obstruction to the urine.

As the disease advances, there will be an irritability or smarting in expelling the urine or semen; and sometimes a discharge of blood at the same time.

An enlargement of the prostate rather increases than contracts the size of the urethra; but it prevents the proper action of the vesical sphincter and the acceleratores urinæ muscles, so that the last drops of urine are with difficulty expelled, and the patient, consequently, is not able to resist the frequent calls to pass the urine. When he begins to make water, it flows properly; but when the bladder is nearly emptied, it passes guttatim. At the same time there is generally a sense of weight and fulness about the anus, with an obscure and throbbing pain. In evacuating the fæces the patient feels as if something filled up the rectum; and the anterior part of the stool is marked by a sulcus. After the expulsion of the motion, the evacuation does not seem to be complete; and during the voiding of the urine, there is a strong desire to go to stool, as if a considerable quantity of fæces could be evacuated; but this inclination arises from the pressure of the enlarged gland. When the enlarged prostate has become so bulky as to prevent, in a great measure, the egress of the urine, the efforts of the patient will often obstruct it altogether; the sides of the canal will contract, and the abdominal muscles will press upon the neck of the bladder against the prostate, and close the canal; the patient therefore will void his urine better when no efforts are made.

This disease cannot always be ascertained by anal examination, as the enlargement sometimes projects into the neck of the bladder, and this enlargement consists of its third or middle lobe, but by an examination with the sound, it may be ascertained very distinctly, the anterior projecting part of the prostate proving an obstacle to its introduction. In this case it will be necessary to give the instrument a greater curve than is usual, or assist it to tilt over the gland by pressing the beak upwards by the finger passed into the rectum. The obstruction ought never to be overcome by violence with the catheter, or a false passage may be made through the gland.

* Continued from page 568.

An abnormal coldness and lividity of the glans will sometimes be found symptomatic of an enlargement of the prostate. As there are different stages in the progress of the disease, they will be considered separately.

Inflammatory Stage.—It is not asserted that there is a plegmonous inflammation in every enlargement of the prostate, nevertheless it does sometimes occur, and it is indicated by pain and tumour in perineo, and by retention of urine.

This condition of the prostate will best be subdued by local bleeding, especially by a large number of leeches applied over the site of the gland, by the warm bath, and by brisk purgatives. The patient is to be kept on low diet, in perfect rest, and in the horizontal position. After the evacuation by the bowels, if there be much pain, opiate enemata should be employed; at the same time it will probably be necessary to draw off the urine with a small elastic-gum catheter; at any rate the urine should never be suffered to remain in the bladder longer than twenty-four hours. If the disease should not yield to the above treatment, blisters may be applied to the perineum.

Abscess of the Prostate.— When suppuration has taken place in the gland, besides the ordinary disturbance of the system, indicative of the formation of matter, a soft tumour will be felt in the perineum, and by pressing the gland between the rectum and perineum, a fluctuation can sometimes be felt. The abscess may open spontaneously into the rectum or urethra, or through the perineum.

If there be great tension, evident fluctuation, or a tendency to gangrene, an opening must be made through the perineum, as it is desirable that the outlet should take place there.

Sometimes gangrene of the bladder takes place near the prostate, and the slough separates. If this happen at the lateral parts of the bladder, a permanent incontinence of urine is to be dreaded. The sore should be dressed down, and a catheter kept in the bladder. It may also be useful to introduce a bougie occasionally, to keep the perineal passage perviable.

From the violent efforts of the patient to make water, the abscess may burst into the urethra; if so, he finds ease at once, and speedily recovers. The same thing may happen from the introduction of a catheter or bougie. Sometimes a large quantity of matter is discharged per anum. In this case emollient injections may be used, but no advantage will be derived from external applications. After the rupture of the abscess bark may be given, with a nutritive diet.

Enlargement, with Induration of the Prostate.—In this condition of the gland, the patient suffers principally from the effects of pressure. The pain is less severe, and the disease less rapid, than in the former case. The indications are, to attempt a resolution, and if this cannot be accomplished, to palliate the symptoms.

It is to be feared that no remedies are possessed by medical science of any determinate power to act upon the prostate gland affected with enlargement and induration. It is usual to give small doses of mercury, with the extract of hemlock, but the former often exasperates the disease, and particularly when used locally as an ointment. The chief remedies from which benefit is derived are blisters and a seton. These, especially the latter, have been found useful in several instances. If the patient is not able to make water, or to empty his bladder, it will be necessary to pass the catheter three times daily, and occasionally it may be useful to leave the instrument in the bladder. Frequent attacks of strangury ought ever to be prevented,—that is, voiding his urine six or seven times a day, drop by drop, after powerful efforts. Sometimes the introduction of a bougie, by separating the sides of the cavity, will enable him to discharge his water. The bowels are to be kept open, and opium may be given.

The best way of administering opium is to make up two or three grains in a pill, and to use it as a suppository. One or two of these may be introduced up the rectum every day, when there is any great degree of irritation. The pill may be placed upon the top of a glyster-pipe, and so pushed up the rectum, and then anything (a bougie for instance,) passed through the tube will dislodge the suppository, and leave it near the posterior part of the prostate.

This plan of applying opium locally has been adopted with much palliative advantage in cancer of the uterus.

Constipation may become the cause of retention of urine. Some persons have a stool only once in seven, ten, or fourteen days. The fæces thus accumulated may press on the neck of the bladder, and obstruct the passage of the urine.

The water is to be drawn off with the catheter, but so long as the fæcal pressure remains, the ischuria will continue. A glyster is the best remedy, and by evacuating the fæces, will effectually relieve the patient.

Hæmorrhoids.—The veins of the rectum being in a congested and tumefied state, may also compress the neck of the bladder, and if they are high up and varicose, suppression of urine may supervene, and be attended with alarming symptoms.

There may be no external appearance of piles, and yet, upon examining the rectum, it may be found filled up with grape-like tumours. These sometimes suppurate, discharge largely, and then get well. Occasionally, from continued pressure, they become gangrenous, and drop off.

Piles are often relieved by clysters; if not, leeches, or the lancet, may be employed. Clysters will be found the best purgatives. When they cannot be used, the mildest aperients are to be substituted,—such as manna, or the precipitated sulphur; the

patient should at the same time sit over the steam of hot water. Suppositories are hardly admissible, but should there be much pain, a solution of opium may be injected into the rectum. The best clyster will be a pint of broth, a fluid-ounce of castor oil, two drachms of the balsam of copaiba, and a few drops of laudanum, (if there be much pain,) thrown up twice a day.

Ischuria Urethralis.—1. *Inflammation of Cowper's Glands.* These are situated near the bulb of the urethra, and are often affected in violent gonorrhœa.

The nature of this disease may generally be known by the seat of the tumour. If suppuration takes place the matter may be evacuated by the excretory ducts of the glands into the urethra, or adhesions having been formed in the cellular membrane below, it may be evacuated externally.

In the onset of the disease resolution should be attempted by purging, leeching, enemata, and the hip bath; and if required, blood may be taken from the arm. If matter should have formed, it should be let out by the lancet as soon as fluctuation can be felt, lest fistula in perineo be produced.

When first called to this case of retention, it will be proper to pass a small gum catheter to evacuate the urine; or a fine bougie may be substituted, and the water will frequently flow by the side of it. The catheter should always be passed with caution, keeping the point as much as possible against the upper part of the urethra that it may glide over the enlargement; but it will sometimes unavoidably take a false route.

If, when the abscess is opened externally, no urine passes through it, it proves that the urethra has not been perforated; but though no urine passes through the opening at first, a slough may separate several days afterwards, and then the urine may escape through the aperture. Fistula in perineo will of course be the result.

When the urethra has been perforated, and, is consequently contracted, it will be necessary to employ bougies; and when induration remains about this part of the urethra, it will often yield to mercury, but is very apt to return from any occasional cause.

2. *Abscess in the Cellular Membrane between the Urethra and Perineum.* This may be the consequence of gonorrhœa, falls and blows, or from obstructions or erosions of the urethra.

If, from either of these causes there be an opening into the urethra, the urine may not only make its way into the cellular tissue, but extend as far as the tuber ischii and sphincter ani, the patient, perhaps, being able to make water in some degree all the time. Sometimes the urine will fill the cellular membrane of the scrotum and penis, which will quickly run into mortification, or produce the erysipelatous œdema or abscess.

The treatment of this case is to evacuate the infiltrated urine by adequate incisions into the scrotum and perineum, or else there will be extensive sloughing. The patient is to be purged, and if necessary, the urine is to be drawn off; but the catheter ought not to be left in the bladder lest it should irritate the urethra. The parts are to be bathed with spirit and hot water and bark should be administered internally. Sometimes the perineum and part of the urethra have been destroyed; and yet with care the patient has recovered.

If there be no stricture between the aperture and glans penis, no particular advantage can arise from keeping the catheter in the bladder, or the employment of bougies before the inflammation has subsided, and the parts are beginning to heal; if, however, the parts are long in healing, the catheter may be kept in, and when the abscess has nearly healed, a bougie may be introduced every day.

If the aperture remain fistulous, the daily introduction of a catgut bougie into it, smeared with blistering ointment, may perhaps dispose the sinus to heal.

3. *Effusion of Blood into the Cellular Membrane.* This cause may prevent the evacuation of urine, and it generally arises from violent contusion of the penis. Free scarifications are to be made so as to evacuate the fluid, which has flowed into the tissue, and such dressings are to be applied as are adapted to contused parts in danger of gangrene.

4. *Sloughing of the Corpus spongiosum.* This may become a cause of ischuria. When an ulcer has destroyed the glans, or a part of the urethra beneath the integuments, the aperture of the canal will become so contracted, that the stream of urine will gradually diminish, and at last become obstructed altogether. The part of the canal behind the contraction will be dilated, whilst the urine will issue in a very small stream through the integuments. This state of the parts may be relieved by introducing a fine probe through the aperture, and by cutting upon it so as to divide the urethra sufficiently; a bougie must then be introduced, taking it out when the patient has occasion to make water.

5. *Phymosis Infantum* may be considered another cause of ischuria.

Infants are born with a prepuce generally so narrow as to prevent the glans being uncovered; and if there be room for the urine to pass out, it is all that is necessary; but if there be no aperture, or if it be too small, retention must take place within the cavity of the prepuce.

This tightness of the prepuce will not be perceived till three or four hours after birth, when the child will appear uneasy, and a swelling will begin to form between the glans penis, and pubes, which goes on increasing till it appears like a hydrocele, the narrowest part being towards the symphisis pubis, and the broadest at the extremity.

When there is any (the least,) aperture, a fine probe or small director should be passed through it, and the

prepuce divided up to the corona glandis; if it be quite closed, an opening must, of course, be first made into the cavity.

6. *Calculi in the Urethra* is another cause of retention of urine; and there are other causes peculiar to women, such as excrescences about the meatus urinæ, prolapse or retroversion of the uterus, prolapse of the vagina, and accumulation of the menstrual fluid in cases of imperforate hymen, all of which are to be treated according to their respective requirements.

Rupture of the Bladder.—Both sexes are liable to this sad result. When it takes place from the pressure of the cervix uteri on the neck of the bladder in cases of retroversion, there must, necessarily, be great inattention on the part of the practitioner. There may be, certainly, some difficulty in introducing the catheter, but this may generally be accomplished, and if it cannot, the bladder may be punctured.

Rupture may be also produced by pressure of the child's head in a labour which has lasted many days; when, therefore, but little water is passed, whatever may be said by the nurse in attendance to the contrary, it is probable that the urine is accumulating in the bladder, and the catheter ought to be introduced without delay.

[The young practitioner, when conducting a tedious labour, ought frequently to examine the state of the bladder, otherwise it may gradually become distended without his being at all aware of it, and suddenly burst into the abdominal cavity.]

The bladder generally ruptures near the fundus. The symptoms indicating the event are a sudden sensation of something having given way, severe peritonitic pain, tension of the belly, and constant vomiting of a dark-coloured fluid, and if the catheter be introduced, no urine, or else a very small quantity of turbid and fœtid urine will be evacuated.

Patients in general die in three days after the rupture. The abdominal viscera, as well as the peritoneum, are found after death highly inflamed from the irritation of the acrid urine.

Rupture of the bladder may be occasioned by falls, and such a result may be suspected by the pain and tension of the abdomen, and by there being no desire to make water. Death always follows this result in a few days.

It seems rather extraordinary that after rupture has taken place, a patient shall void a few ounces of urine through the catheter; but as the rupture usually takes place at the fundus, it may easily be supposed that a small quantity of urine may remain towards the neck of the bladder.

The bladder is sometimes ruptured from a stone in its cavity. Whenever the bladder is in a morbid state and retention of urine comes on, mortification often takes place in forty-eight hours.

In the treatment of this case, no especial good can be done. Pain may be alleviated by the warm bath and opium; but no particular advantage would be derived from puncturing the abdomen to evacuate the water.

[I cannot agree on this point with Mr. Pearson. Puncturing the abdomen and evacuating the effused urine, and washing out the peritoneal cavity by means of a stomach-pump, at the same time keeping a catheter in the bladder would, at the very least, give the patient the possibility of an escape from death, which must inevitably follow if no attempt be made to evacuate the urine from the peritoneal cavity. If the stomach can be cleared of a poison by this means, through a natural channel, why should not the peritoneal cavity be cleared of the poison of urine through an artificial one?]

If the bladder has been wounded by a ball near the pubes, the water may be evacuated through the wound, and the patient might recover.

Cystocele.—This is a displacement of part of the bladder, and was not understood by the ancients, except Lanertus, who gave a good account of it. It consists of a partial prolapse of the bladder, either through the abdominal rings, or into the vagina.

The part recedes under pressure, which causes a desire to pass the urine. This protrusion may be incarcerated as an intestinal hernia, but in its incipient state it may generally be remedied by the application of a proper truss or pessary.

[Some years ago I met with a case of vaginal cystocele, in an elderly lady, which for a long time passed unnoticed, and became extremely difficult of management.]

(*To be continued.*)

CASE OF POISONING BY YEW BERRIES.

By John Lloyd, Esq., Surgeon, Bath.

(Read at the Quarterly Meeting of the Bath and Bristol Branch of the Provincial Medical and Surgical Association.)

I was requested a few days since by your Honorary Secretary, Mr. Bartrum, to present to this meeting the particulars of a case of poisoning by yew berries, and as but few cases are on record, and this being the only one in sixteen years of extensive practice I had met with, I did not hesitate to comply with his desire, and considered a brief history of the tree and its qualities would not be uninteresting to this Society.

Taxus baccata is the Latin name of the tree; derived from τοξον, an arrow. The common name yew is derived from the Celtic word iw, meaning green, its leaves being persistent. It is of the coniferous order. It and the savin, I believe, are the only two poisonous plants of that order in this country. It was planted by our ancestors in churchyards, as a place of security, on account of its furnishing the best bows; and I see in "Castle's Botany," that by a statute of the 5th of Edward the 3rd, every Englishman was directed to have a bow

of his own height, and the supply of them being too scanty, it was ordered that all ships trading to Venice should be obliged to bring home ten bow-staves. It is very long lived, and grows to a very large size. In the neighbourhood of Bath there are a great many trees, mostly of small dimensions. It has for ages been deemed poisonous. The physician Dioscorides, in Nero's time, (who, for that age was a learned toxicologist, and wrote on the Materia Medica,) Galen, and Pliny, also attribute the most poisonous effects to it; and Cæsar, in the sixth book of his Gallic war, speaking of the defeat of Cativolcus, king of part of the Eburones, mentions that he poisoned himself. His words are—"taxo, cujus magna in Gallia Germaniaque copia est, se exanimavit." Virgil, in his Georgics, expresses himself—"Si fugeant examina taxos."

Dr. Loder states the extract to have narcotic properties, and to be useful in rheumatism, and some other diseases Dr. Percival relates that the fresh leaves were administered to three children for worms. Yawning and listlessness soon came on; the eldest vomited a little, and complained of pain, but the others expressed no pain. They all died within a few hours of each other. Gerard, in his "Herbal," speaks of its poisonous qualities; and a very interesting case is related by Mr. Hurst, of Mansfield, which resembles my own in some particulars, and both were induced by the nuts of the drupe.

Experiments.—From my time being limited, I was only able to perform a few experiments on fishes, which I now lay before you.

1. I procured some perch, and put three in six gallons of river water, and mixed with the water three ounces of the macerated drupe. Two of the fish died in twelve hours, the other is now living.

2. Three fish were put in six gallons of river water, and two ounces of leaves, previously macerated, were mixed in it. They lived eight hours.

3. One ounce of the nuts of the drupes, not bruised, were macerated, and placed in six gallons of river water; three fish were put in. They lived seven hours.

4. Three fish were put in six gallons of river water, and one ounce of the bruised nuts, previously macerated, mixed in it. They lived two hours.

Now, the effect of the drupe on the three fish, was not well marked; one lived, the others died, and were, after death, flaccid, their pigment remaining unimpaired. Not so on those of experiments 2, 3, and 4; they all died, and were very rigid, more so than is generally found in dead fish, for it is well known in their natural state their skins are tensely stretched over, and closely adherent to the muscular substance underneath; this rigidity was accompanied with their pigment, losing some of its brilliancy.

In speaking to a gentleman of the effects of the yew poison, he related the circumstance of a man, coming with a donkey to sell sand, when the animal ate of the leaves for some time, and after it had finished, in half an hour it died.

I now purpose giving you the history of the case occurring to myself.

On the 22nd of August last, a fine boy, 4 years old, ate many of the berries and nuts of the yew; two hours after he vomited, and was seized with convulsions, coma, and purging; dilated pupils; respiration frequent; lungs engorged; tongue excoriated; countenance pale and depressed; pulse small and wiry; extremities cold. This was the state I found him in. An emetic was given, which cleared his stomach. Leeches were applied to the head, with abatement of the convulsions. Purgatives were given, to assist the natural efforts, and a teacupful and a half of drupes and nuts were voided; convulsions still continuing; leeches during the first day were again applied, with marked relief. Forty or fifty mucous evacuations, with many nuts in them, were passed for several days, accompanied with tormina and tenesmus of the most excruciating kind; these continued, with great prostration, for seven or ten days, allowing only of castor oil and anodynes, with wine, and a farinaceous diet, to be administered, at which time the evacuations began to contain vast quantities of pus, and petechiæ made their appearance on the fingers and toes, also ecchymoses. The vital powers from the beginning were so depressed, as to baffle anything like an active curative plan from being used, notwithstanding violent gastric and muco-enteric inflammation existed. There was pain to the last, before and after each evacuation, with prolapsus ani. He died nineteen days after eating the drupes and nuts.

I have much to deplore, notwithstanding the utmost endeavours of the Coroner and myself, that no *post-mortem* examination could be obtained.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, NOVEMBER 29, 1848.

We have received a letter on the subject of the gross injustice done to the medical profession in the appointments made under the Public Health Bill, to which it had been our wish to direct the attention of the Members of the Association in the present number at some length. The desire, however, of giving insertion without curtailment, to the admirable, and at this crisis, vitally important, lecture of Dr. C. W. Bell, on the nature and treatment of the epidemic cholera, together with some other considerations, which it is unnecessary now to enter into, has interfered with our purpose, and we have been in consequence compelled, not only to defer this subject to another, though we hope not distant, period, but also to make other alterations in respect to some communications intended to have been inserted in the present number of the Journal, which we trust their respective authors will excuse. All omissions of this kind it will be our study to remedy as early as opportunity and attendant circumstances will permit; but there is one point which we trust

our valued correspondents will endeavour to bear in mind, that lengthy controversial discussions must ever be inconvenient, while they are for the most part as distasteful to the generality of readers, as they cannot but prove unsatisfactory to the parties engaged in them. One of these discussions which bas been for some time going on in our pages, closes, we are happy to say, with the present number. Another will, we fear, yet occupy a few more of our columns, but we entreat the combatants on either side to remember, that high as they both stand in the estimation of their professional brethren, such displays from men of their acquirements can scarcely take place, without, in some degree, compromising the distinguished consideration in which they are both held, and bringing into disrepute researches of unquestionable value.

Reviews.

An Introduction to Practical Chemistry, including Analysis. By JOHN E. BOWMAN, Demonstrator of Chemistry in King's College. London: 1848. 18mo, pp. 280.

In this work we find instructions for performing the principal analytical operations of chemistry. It is chiefly intended for the student, and contains in the introductory part a full explanation of the chemical symbols now in use. The author divides his subject into five parts, in the first of which is treated of, in succession, the operations of pneumatic chemistry, of distillation, glass-working, the blow-pipe, specific gravity, of heating substances in gases, and of estimating the quantities of alkalies and acids. The second part treats of the actions of re-agents on bases and acids; the third part, of the qualitative analysis of substances, the composition of which is unknown; the fourth part of quantitative analysis, and the fifth part, is devoted to the examination of calculi, and of reagents. An appendix is added, comprising various tables of weights and measures,—of the strength of certain acid and alkaline solutions, and of alcohol and æther, at different densities,—of freezing mixtures, &c., together with a glossary of chemical terms.

The work is illustrated by numerous wood-cuts of the instruments used, and the operations performed, and is altogether well calculated to prepare the student for the study of the more elaborate treatises on chemical analysis, by Rose, Faraday, Fresenius, &c. Both as an introduction to experimental and analytical chemistry, and a useful guide in the acquirement of the practical facts of the science, we have great pleasure in commending it to the attention of our readers.

Wonders displayed by the Human Body in its Endurance of Injury. From the Portfolio of Delta. With numerous etchings by the Author. London, 1848, 8vo, pp. 39.

This is a curious pamphlet, written in a quaint style, and is intended to exemplify by many extraordinary narratives, collected from various sources—ancient as well as modern, the powers of endurance possessed by the human body. We have thus brought before us a record of extraordinary cases of the manifestation of animal electricity, of spontaneous combustion, of the endurance of injury as shown in the swallowing and partial digestion of spoons, knives, cups, &c., in remarkable gun-shot wounds, and in cases of substances lodged and retained in various parts of the human body.

We observe that almost the last case noticed in the work, is that of the boy William Mills, recorded by Messrs. Davis and Sheward, of Upton-upon-Severn, in one of the early volumes of the "Transactions of the Provincial Medical and Surgical Association." In this case, as many of our readers will recollect, a portion of a telescope toasting-fork, which had been converted into a gun by the unfortunate youth, was blown off, entering the chest between the third and fourth ribs of the right side, and was ultimately found firmly fixed in the right ventricle of the heart, the boy living thirty-seven days after the occurrence of the accident. An etching from the original drawing in the "Transactions" is given by the author, though he omits to state the source whence the case has been taken.

On Medical Education: an Introductory Lecture, delivered at the Lirerpool Infirmary School of Medicine, at the Opening of the Medical Session. 1847. By JOSEPH DICKINSON, M.A., M.D., F.L.S., &c., Physician to the Liverpool Infirmary, and Lecturer on the Theory and Practice of Medicine. London and Liverpool. 1848.

An Introductory Lecture to Clinical Surgery, delivered at the Liverpool Northern Hospital, at the Opening of the Session, October 4th, 1848. By HENRY STUBBS, F.R.C.S., Senior Surgeon to the Hospital. Liverpool. 1848.

A review of Introductory Lectures is scarcely consistent with the objects of our pages. The members of the Provincial Association are for the most part practically acquainted with the subjects treated of in such lectures, and do not require that the principles of medical education should be anew pointed out to them. In another point of view, however, we cannot but regard the lectures of this description, which from time to time come before us, as affording important data by which to judge of the mode of conducting, and to estimate the value of, our Provincial Medical Schools.

Looking then at them in this light, the lectures before us are in no respect inferior to those delivered at our metropolitan hospitals and schools, and evidence the same sound views of the subjects on which they treat, of the objects to be sought after by the student, and of the manner of attaining those objects.

There is a collateral advantage attending the provincial schools of medicine which cannot but be felt by very many of the young men who are educated in these schools. Each institution of this description is connected with a hospital, which may be said to be the centre of a district where the diseases and peculiar accidents of the locality are collected together and exemplified. How valuable then to the student who will probably be called upon to practise in the locality, to see disease, and to learn to treat it, under the precise form in which it will occur to his notice in after life.

In reference to the lectures before us we may observe, that Liverpool will present opportunities for studying the diseases of a maritime population inferior to no other place in the world. It is unnecessary to quote instances to this effect, as it is sufficiently evident, that with a population of nearly half a million, the first seaport in the world cannot but afford most ample opportunities to the student, of seeing disease in all its forms; while, as illustrating the diseases and accidents to which seamen are liable, its several hospitals must at all times be resorted to with especial advantage.

In conclusion, we may observe, that Dr. Dickenson's lecture is distinguished by sound and healthy philosophical views of medical tuition—Mr. Stubbs' by the clearness and method with which the attention of the student is directed to the several objects of his professional education.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

August 3rd, 1847.

S. W. Burbury, Esq., in the Chair.

LARGE ANEURISM OF THE ABDOMINAL AORTA.

Mr. Pemberton brought before the Society the followiug case:—

J. G., aged 32, (admitted into the General Hospital, under Dr. J. Johnstone, June 30, 1848,) a plasterer, a tall, pale and somewhat emaciated-looking man. He was admitted as a case of lateral curvature of the spine; he had complained of pain across the back and sides for fourteen months, and had been under treatment for lumbago and rheumatism. Never had cough nor spitting; and had lived temperately and moderately. Had never suffered from a blow in the region of the pain. Had only worked one month since last November, his health and strength from the period mentioned having failed him. Father and mother living. On examining the spine, a heaving pulsation was distinguished in the situation corresponding to the curved vertebræ, and on firmly grasping the part a distinct tumour could be located. No bruit was audible unless the stethoscope was firmly pushed down, then a marked bruit became audible. In front the pulsation corresponded to a line drawn opposite to the umbilicus, and was more evident here than behind; sounds of lungs and heart natural, though the heart's sound was feeble. His powers of life appeared very low; pulse feeble; tongue clean and moist; appetite indifferent; bowels constipated.

July 4th. Suffered severe neuralgic pains in left lower extremity; the limb drawn up; countenance anxious and pinched; surface perspiring from pain; relieved by an opiate. The pain continued through the night of July the 5th, and he sank very rapidly and died next morning.

On account of his extreme deafness it was difficult to gain information from him. On dissection, the left pleura was almost entirely occupied by blood, separated into serum and coagulum; the lung collapsed; about two inches on the left side of the aortic opening in the diaphragm, was a lacerated opening through the diaphragm, through which the blood had entered the chest. A large tumour entirely filled up the left lumbar region of the abdomen, the kidney embedded in its fat being raised and pushed upwards and forwards from its natural position. The tumour, which had the appearance of the natural parts of that situation altered by effused blood, extended as far as the centre of the iliac fossa of that side; and over its anterior surface, closely bound down to it, ran the descending and sigmoid colon. The anterior branches of the aorta were traced from their origin unaltered. The aorta, the vertebræ, and the soft parts connected, having been removed, and the aorta slit up, an oval opening, three quarters of an inch in long axis, and half an inch transversely, presented itself in the posterior aspect of the artery, at the situation of the cœliac axis; it communicated with the sac of the aneurism, which was formed of the vertebræ and lumbar muscles closed in by the adjacent parts. The sac of the aneurism seemed first to have directed itself to the right, thence across the spine to the left, extending both upwards and downwards, and finally bursting through the diaphragm, to have reached the pleura. The sac was of great size, about as large as one's two hands placed together by the extremities of the fingers and thumbs; its walls were in some places extremely firm, and it was difficult to distinguish the layers of fibrin (so consolidated were they,) from the altered muscular structure of the parts adjacent. Immense coagula of blood in various stages of firmness, occupied its interior. The bodies of the last dorsal, and first three lumbar vertebræ, were softened, partially absorbed, (portions lying loosely about,) and completely denuded; the intervetebral substance was scarcely at all affected, its convex aspect, in contact with the aneurism, presenting a striking contrast to the bony structures around. The transverse process of the first lumbar vertebra was entirely separated from its vertebra, by the ravages of the aneurism. The heart was healthy, very small, almost bloodless; and the general condition of all the other viscera was that of extreme absence of blood. The left lung adhered, by old pleuritic bands, to the diaphragm, immediately adjacent to the ulcerated opening; the right lung perfectly healthy. No

tubercles any where were apparent. It should be added, that the blood in the pleura had evidently been recently poured out, probably in the night preceding his death.

HYDATID TUMOURS OF THE LIVER, ULCERATING THROUGH THE DIAPHRAGM, AND THROUGH THE WALLS OF THE STOMACH: TUBERCLES IN THE LUNGS.

Mr. O. Pemberton communicated to the Society the following case:—

B. S., admitted into the General Hospital under Dr. Eccles, early in May, a yellowish cadaverous looking man, a worker at an iron furnace. Twelve weeks ago was seized with aching across the loins and in the region of the liver; a fortnight after he became jaundiced. He had about ten blisters applied over the liver, and he was salivated. He had never had jaundice before, nor had any other members of his family. His general condition at his admission was extremely wretched, and he seemed to lack any power of restoration in his system. Under treatment the jaundice much diminished, and his state improved, but tenderness remained in the abdomen. There was distinct hardness in the epigastrium.

May 29th. In consequence of imprudence he became worse. Countenance extremely anxious; lay with his legs bent on his abdomen, and abdomen tender all over; pulse small, 140; tongue inclined to be dry; marked rigors at intervals. Leeches had failed to relieve him, but a large blister to the abdomen, and the free administration of tonics, acted almost magically in relieving him. He became convalescent, and left the hospital.

June 30th. Readmitted. Emaciation advanced; excessive misery depicted in his countenance; and he suffers awfully from the pains in his loins and in his shoulders. Opium, combined with ammonia, and afterwards with nitric acid, was administered, and subsequently iodide of potassium in infusion of quassia.

July 26th. Urine, of specific gravity 1021, acid, no albumen nor sugar; countenance anxious and pinched; surface perspiring; has emaciated rapidly the last few days; the swelling towards the hypochondrium (previously noticed,) is more and more distinct, and more painful; he complains most severely of pain in his left side. He died on the 29th.

Dissection.—Body greatly emaciated. *Thorax:*—The right pleura adherent throughout by old bands; the right lung studded throughout with large tubercular deposits, in a crude condition; the left lung in its upper part presented some scattered tubercular deposits, whilst the lower lobe firmly adhered to the diaphragm; on breaking through the attachment of the right lung to the diaphragm, it was found to be ulcerated through, and the process of ulceration had extended itself, for a small space, into the substance of the right lung. *Heart* healthy. *Abdomen:*—The liver occupied an unusually large space; the diaphragm was pushed up, so as to limit the right thorax to half its natural capacity, and the enormously-large right lobe extended over into the left hypochondrium; the edge of the stomach was just visible, the stomach having been pushed completely to the left side, and adhering firmly to what appeared to be the remains of the left lobe of the liver. On removing the liver and the stomach, and on opening the latter, several large hydatid cysts were brought into view, and running in a direction immediately in a line with the orifices. In the smaller curvature were seven or eight dark and apparently sphacelated spots in the mucous membrane; these ulcerated spots were well marked, and were covered by blackened lymph. About an inch from the pyloric orifice, an aperture in the wall of the stomach, capable of admitting the extremity of the index finger, communicated with a small cyst in the left lobe of the liver; this cyst appeared contracted, and to have been developed at the expense of the left lobe of the organ, as it constituted nearly all that remained of that portion of the liver. Smaller hydatid cysts were contained within this cavity, the walls of which were firm, and were covered by a purulent secretion. Two-thirds of the right lobe of the liver was occupied by a large cyst, containing abundant, very large, hydatid cysts, some enclosed within others, and besides a large collection of pus; the wall of this cavity was thickened, and nearly resembled the interior of an old pulmonary vomica. Towards that point of the liver attached to the diaphragm, the cyst had given way, and the process of ulceration had extended itself so as to perforate the diaphragm, and to adhere to, and to cause partial ulceration of, the inferior portion of the right lung. The ductus communis choledochus was enlarged to the dimension of a goose-quill. Spleen large and healthy. The remaining viscera natural. *Brain* not examined.

TUBERCULAR PERITONITIS: PERFORATING ULCERS OF INTESTINES.

Dr. Russell commnicated the following particulars to the Society:—

M. C., aged 9, first came under my care at the General Dispensary, Oct. 9, 1847, in an early stage of cachexia; she was small and ill-nourished; she suffered from ill-defined pains in her limbs and in her back, and was subject to occasional fits of severe dyspnœa, with palpitation. She had been ailing for some time, and had been losing flesh slowly for six months, or longer. No evidence of disease in her chest; her belly was very large, and the integument around the navel presented a peculiar appearance, like an extended cicatrix. She did not make much progress under treatment, and I soon lost sight of her till Feb. 12, 1848. I should state, that she inherited consumption by her mother's side, and that her sisters are weakly. She was an eight months' child.

Feb. 12th.—She manifested every sign of the progress of her disease; was much emaciated; had a quick and very small pulse; was very feeble. She had no symptoms to direct attention to the chest, and the stethoscope did not detect any abnormal sound. She was suffering from severe pain at the bottom of the belly, which occurred in paroxysms, perhaps four or five times a day, sometimes during micturition, or when she was walking, or, perhaps, when she was still; her bowels were relaxed; abdomen distended with flatus, and rather tender; no fluid in the peritoneal cavity. Her urine was high-coloured, sometimes abundant; its specific gravity was 1.022; it was of a deep yellow, and the microscope detected numerous prisms of triple phosphate in it. Her illness was protracted till the beginning of June, but did not present any fresh symptom of interest until shortly before her death. The pain in her bowels continued

very harrassing for some time, frequently changing its situation. It afterwards seemed to yield to sedatives and fomentations for a time; but during the last two months of her life it was extremely distressing, and required large opiates for its relief. The abdomen became more and more distended, and the ill-developed integument around the navel pointed. She had no chest symptoms, except a cough, which lasted for a short time only, and auscultation did not detect any evidence of other disease than some bronchitis at the base of the lungs, during that term. She was much annoyed by a troublesome eruption of lichen. The treatment was of a tonic and sedative character. For some time her appetite was very voracious, and she eat a large quantity of meat; at the same time she passed very copious stools.

At the end of May emaciation become extreme; the abdomen very tense and tender; frequent paroxysms of severe pain, chiefly around the umbilicus and in the pudenda; micturition painful and difficult.

On the morning of May 30th, her mother stated that a copious discharge of liquid stool took place suddenly from the privates, followed by great relief, and that about noon of the same day, the integument near the navel burst, and gave exit to a large quantity of purulent matter, followed immediately by a discharge of fæces through the opening. She lived till June 8th, much relieved from all urgent symptoms; liquid fæcal matter passed frequently down the vagina, often containing portions of food eaten an hour or two before, and not digested,—as peas, small fragments of meat, &c. A much smaller quantity of fæcal matter issued by the ulcerated opening in the wall of the abdomen, and this only when she sat up.

Dissection.—I was out of town, and am indebted to Mr. Shaw for making the examination.

The intestines were universally and intimately glued together, so as to form but one mass, they also adhered generally to the parietes of the abdomen. The peritoneal cavity contained some fæcal matter; the surface of the intestine was studded with tubercular matter in masses, from the size of a pea to that of a damson. The external opening near the navel was found to communicate with the canal of the intestine, but the complete matting together of all the intestines rendered it impossible to say with what part of the canal. There were besides, five or six other ulcers penetrating the intestines in different parts, through which fæcal matter could be squeezed; some were large enough to admit a walnut. There was a communication effected by ulceration between the rectum and the vagina, so that the finger passed into the vagina readily entered the rectum. Liver, kidneys, and bladder healthy. Lungs unadherent; quite healthy; no tubercle was found in them, though they were not sliced very minutely. Heart also healthy.

STRICTURE OF THE RECTUM.

The history of this case was furnished by Dr. Russell.

June 1st. I was requested to see a poor woman 53 years of age; she had had several children. She complained of great pain in her bowels, and had taken medicine to open them, without effect. The bowels were swollen and tender, and she had constant vomiting. She had no hernia; and on examination per rectum, I could not discover any obstruction. I ordered fomentations in the bowels, and gave her two grains of opium, which I directed should be repeated in the night, if the urgent symptoms continued. When I saw her the following morning she was much relieved in her violent symptoms, but there had been no relief from the bowels. I directed her to drink Palmer's solution of magnesia, to allay her thirst, and if pain or sickness returned, to repeat the pill, and she was to have two injections, with colocynth, during the day. In the evening she was more comfortable, had not taken the second dose of opium, and had had the enema without relief. I gave her one grain of opium. The following morning, having had no sickness for two days, or the bowels not having been relieved, I gave her half a drop of croton oil, with gamboge pill, and a quarter of a grain of opium, and to repeat this dose every second hour. In the evening I found that the pills had caused return of the vomiting; she had passed, from the injections, two or three small pieces of scybalous matter, but the vomiting was continual. The pills were discontinued, and half a drachm of Liquor Opii Sed. given in peppermint water, and the injections continued; the remainder of the treatment consisted of opium by the mouth, with injections, and with varying prospects of relief she continued (the vomiting never ceasing,) until the 17th of June, when she died. I had proposed to her the operation of opening the colon, but when she understood the annoyance to which she would be subjected, if the operation were successful, she preferred death. The only point of her history previous to her last illness known, was, that she was subject to constipation.

On dissection the entire alimentary canal was found enormously distended with flatus; there was a large quantity of liquid fæces in the colon; no appearance of peritonitis, and no fluid in the abdominal cavity. The only appearance of disease existed in the rectum, which presented, just opposite to the fundus uteri, a stricture, so close that a small blow-pipe alone could pass through it. The stricture was remarkably partial, as though a string were tied round the gut in that point; above and below it the gut was quite healthy; the cellular tissue immediately around the strictured portion, was dense, and there were a few bands of adhesion between the rectum and the base of the uterus. On cutting up the gut, no cicatrix nor ulceration was seen, nor any appearance to throw light on the cause of the stricture. There was not the least indication of recent inflammatory action about the rectum.

CONGESTED LUNGS: CIRRHOSIS OF THE LIVER: TUBERCLES OF THE PLEURA, PERITONEUM, AND INTESTINES; NONE IN THE LUNGS.

Dr. Fletcher exhibited specimens of congested lungs, enlarged spleen, and of the commencement of cirrhosis of the liver, all free from tubercles, and a portion of the intestines, and of the omentum, studded with tubercles, and very closely adherent, and a portion of the pleura, in which numerous small tubercles existed. He gave the following history of the case:—

W. C., aged 30, admitted into the General Hospital, June 27th, under Dr. Fletcher, a blacksmith, spare, at times intemperate; convalescent from influenza for six

weeks. A fortnight ago he caught cold, had abdominal pains, rapid swelling of abdomen took place, and cough, with some dyspnœa supervened. His father died of phthisis at 44; mother living and healthy. He has still (June 27th,) slight cough and expectoration; skin moist; tongue coated with white fur; pulse 117; urine high coloured; bowels regular. He complains of soreness over the abdomen, which is large and tense; a creaking sound is obtainable by moving the hand firmly over the abdominal parieties. Hirud. xvj., abdomini. Pil. Hydrarg. et Pil. Scillæ, utrq., gr. v.; omni nocte sumend. Potass. Iodid., gr. v.; Infus. Digitalis, oz. ss.; Mist. Camph., oz. j., ter die sumend. His urine was of specific gravity, 1.030, and did not contain albumen. July 1st. Infricand. abdom. Ung. Iodinii. 5th. Emaciation increased, night sweats, great thirst, frequent cough. Linctus Morph. Potass. Bitartr., ex aqua, situ urgente. One glass of wine daily, arrowroot, &c. He continued in the same state, and died July 18th.

Dissection.—Body emaciated; abdomen greatly enlarged; right pleura contained a very large quantity of yellowish serum; left pleura firmly adherent throughout, it had become thickened, and in parts almost cartilaginous; its cavity contained a smaller quantity of serum; upon the right pleura pulmonalis and upon the external aspect of the pericardium, near its reflexion over the great vessels, were some whitish tubercular deposits. Heart healthy. Both lungs presented evidence of various stages of congestion; the lower lobes of the right lung were nearly carnefied. No tubercles existed in the lungs. The abdominal cavity did not contain any effused fluid, but the whole viscera were agglutinated together by an earth-coloured tenacious lymph. The whole peritoneum was thickened by the deposit of tubercles, to the condition of a tough membrane, and its layers in the omentum resembled in appearance, on section, the natural tissue of the pancreas. The liver was contracted in size, uneven in places on its external surface, pale-brown in colour, and evidently cirrhosed; it weighed three pounds one ounce. The spleen greatly enlarged, weighing two pounds three ounces, its tissue healthy. Kidneys healthy in textnre, but congested. The hollow viscera adherent to each other, distended by flatus, and covered in places by large circumscribed patches of dirty lymph. On stripping off this false membrane, numerous tubercular granulations of small size were brought into view, developed in the tissue of the intestine. Pancreas healthy. Brain, with its membranes, healthy.

PLEURITIS: PARACENTESIS THORACIS: TUBERCULATED PERITONEUM, &c.: NO TUBERCLES IN THE LUNGS.

Dr. Fletcher exhibited the lungs, which were free from tubercles, and a portion of the parietal pleura and pericardium, between which there was a considerable deposit of tubercular matter; portions of the intestines and of the omentum; and also of the parieties of the right side of the chest, in which were also deposited a considerable amount of tubercles, and the left kidney, in which was a cyst the size of a small orange, which contained tubercular matter; all taken from a patient, who had, in consequence of suffering from empyema, undergone the operation of paracentesis thoracis.

On the 24th of April, 1848, Dr. Fletcher was summoned to Mr. John Sheath, aged 41, who was much emaciated, and lay in his bed on the right side, imminently suffering from difficulty of breathing.' His habits previous to his illness, which commenced a little before Christmas, were very irregular. He had been very much addicted to intoxication. He had enjoyed very good health. At the commencement of his illness he was attacked with great pains in the right side, cough, and difficulty of breathing, then thirst, and the general symptoms of a sympathetic febrile attack, in fact it appeared, from his account, to have set in as a pleurisy of the right side, but he did not give up drinking until he suffered so much as not to be able to leave his bed.

On examination, Dr. Fletcher found that he could not lie on the left side. The right side of the chest much larger than the left, with the intercostal spaces rather puffed out, and quite motionless in respiration, its parieties laterally and inferiorly were œdematous; a pit, the fourth of an inch in depth, could be made by pressure with the point of the finger. The respiratory actions of the left side of the chest were much greater than normal; the whole of the right side of the chest was quite dull on percussion, whilst the left side was more sonorous than usual. No respiratory sounds were heard on auscultation of the side affected, except just at the top of the chest, whilst on the left side the sound of respiration was quite puerile in character; the breathing very short, and much increased in difficulty by the slightest exertion or inclination towards the left side; he could only lie on the right side. Pulse 120, and feeble; tongue moist; bowels open.

The urgency of the symptoms demanded immediately the operation of paracentesis thoracis, which was performed by Mr. Cartwright, on the 25th, at twelve o'clock, with the trocar and canula, to which the rabbit's intestine is attached, so as to prevent transmission of air into the cavity of the pleura, and a gallon of straw-coloured transparent fluid was drawn off, which coagulated on cooling, and a portion of which was exhibited at the meeting of the Society in May. The right side diminished very much in capacity, became clear on percussion in the upper portions, and less dull all over, and feeble respiration was heard at the superior half after the operation, and the patient expressed himself as very much relieved.

On the 26th and 27th the physical signs and the general state of the patient were improving.

29th. The patient complained of having suffered a slight shivering in the night, and that he did not feel quite so well. The right side seemed fuller, and more dull upon percussion. To take an aperient and a saline mixture.

30th. Somewhat in the same state.

May 1st. On examination the physical signs of the effusion into the pleura were evidently increasing, as also the difficulty of breathing, and the difficulty of lying in any position, but exactly on the right side. A blister to be placed over the right side of the chest, twelve inches by eight, and to be dressed with savine ointment; two grains of calomel night and morning in a pill, and five grains of iodide of potassium three times a-day in camphor mixture.

May 2nd to May 8th. The medicines were continued

during these dates; the blister was kept open at first with savine ointment, but now nearly well; the mouth did not become affected by the calomel; the right side of the chest much diminished, and the physical signs of effusion and general symptoms much improved.

9th. He complained of a very severe pain in the right lumbar region, for which a blister was applied, and the remedies continued.

10th and 11th. Pain in lumbar region relieved by the blister.

13th. The patient still improving; mouth not sore. A blister to the right side of the chest, nine inches by five; to be dressed with savine ointment. Three grains of calomel night and morning, with five grains of soap and opium pill, and continue the mixture of iodide of potassium.

16th. The blister had risen, and the patient seems generally improved.

20th. Mouth sore. To discontinue the calomel.

24th. Still going on well. To take the calomel every other night. Continue the mixture of iodide of potassium.

30th. The patient going on much about the same; he now occasionally sits up, but still continues very weak; he can lie on either side with comfort, and the general symptoms are much less urgent; the physical signs, however, still indicate effusion to some extent in the right pleura, but the side gradually sinking in, shews absorption to be going on. The counter-irritation and mixture of iodide of potassium to be continued.

June 4th. Still about in the same state.

12th. Tongue red; pulse quick; and pains in the bowels attended with purging. Capt. Mist. Cretæ cochlear. magna duo post sing. dejection. liquid. R. Pulv. Ipecac. Comp., gr. xv., hora somni omni nocte.

13th. Febrile symptoms and diarrhœa improved.

16th. The diarrhœa has entirely subsided and the tongue regained its natural aspect. The chalk mixture to be taken three times a day, the compound ipecacuanha powder to be continued at night, and the counter-irritation to be still kept up on the right side.

He went on in about the same state, the side gradually diminishing until the first of July, when he had a repetition of the pain in the bowels and diarrhœa, which more obstinately resisted the action of remedies; some tincture of opium was added to the chalk mixture; and on the fifth of July the patient was free from pains, but in a very weak state. From this time the weakness increased and the bowels increased in irritation; they became distended, and on applying the hand and moving it slightly laterally, a slight crepitation was felt; and upon the parieties of the right side of the chest, just below the blister, under the integuments covering the cartilages of the ribs, were numerous tubercular substances, which increased in number and size. He gradually got weaker, and died on the 17th of July, at seven a.m.

Post-mortem examination July 18th, 7 a.m., twenty-four hours after death. Body extremely emaciated; numerous tuberculated eminences on the anterior and inferior portion of the right side of the chest, which on examination were found to be true tubercles developed in the subcutaneous and superficial muscular structures. The head was not allowed to be examined. *Chest:*—Left pleura healthy, and free from adhesions; left lung healthy; right pleura thickened, and cartilaginous in its whole extent, and containing tubercular matter where it approximated the pericardium; its cavity contained thickened and broad bands of lymph, passing in all directions so as to form cells, which contained clear, transparent, straw-coloured serum; and the lung bound down to the back of its cavity, lying close down against the spine, and extending from the first to the sixth rib; its structure was condensed, and did not crepitate, but did not contain any tubercles. Heart small, the veins in an enlarged and varicose state. *Abdomen:*—Two quarts of clear serum in the cavity of the abdomen; deposits of tubercles throughout the peritoneum, but more especially in the omentum, which was converted by them into a firm mass, an inch and a half in thickness, and in its structure might be well compared to the pancreas, to which it was very similar; the tubercular deposit was much more abundant on the right side of the abdomen than on the left; the liver was very firmly adherent to the diaphragm, and was on its surface numerously studded with tubercles, which were also, to a small extent, scattered about in its structure; with this exception the liver was healthy, but small in size. *Pancreas* healthy in structure, but studded with tubercles on its surface. *Spleen* small, but healthy. *Kidneys* healthy, with the exception of a cyst on the left, of the size of a small orange, full of cheesy tubercular matter. The rest of the urinary organs healthy.

Dr. Fletcher said that these two cases must form some degree of interest to the Society, as instances of the deposit of tubercles in subjects upwards of fifteen years of age, without any being found to exist in the lungs, the reverse of which is so extensive as to have induced M. Louis to have considered it as an established law, that in cases of tubercular disease, after fifteen years of age, tubercles are always found in the lungs if they are found anywhere. Dr. Fletcher did not mean to say that these cases were sufficient, even when taking into consideration the number of exceptions to this law, to annul it, for at the same time we consider the number of exceptions, we ought to take into consideration the immense increase in *post-mortem* examinations which has taken place since the time M. Louis announced the law, and that they may be taken as only in the proportion of the exceptions which M. Louis spoke of at that time. But, however, it has been thought by some experienced pathologists, that this peculiar class of cases of rapid development of tubercle, especially in the peritoneum, ought not to be considered as cases to be included in M. Louis' remarks, and it is very probable that, on examination, it will be found that such cases as are now before the Society must be excluded if M. Louis' law is still to stand good.

General Retrospect.

PHYSIOLOGY.

ON THE TWO MOVEMENTS OF THE BRAIN,—THE RESPIRATORY AND THE ARTERIAL.

There are two movements of the cerebral substance, the one which corresponds with the dilatation of the arteries, the other to the movements of respiration.

1. *Respiratory movement of the brain.*—The respiratory movement of the brain has been the subject of

memoirs by Haller, and Lamare, &c.; the latter also observed a correspondence between these movements and the flux and reflux of the venous blood. During expiration, the blood flows back from the superior vena cava into the cerebral sinuses, and the brain becomes distended. In inspiration, on the contrary, the blood retires from the brain into the jugulars, and the organ diminishes in bulk. M. Flourens has also investigated the subject, and finds that the blood, which, by its reflux distends the brain, is derived, not as the others suppose, from the jugulars, but from the two great vertebral sinuses.

2. *Arterial movements of the brain.*—In his work on the cerebro-spinal movements, M. Flourens performed his experiments on rabbits, the blood-vessels of which animal were too small to communicate a movement to the cerebral mass, and he accordingly denied its existence. When, however, he repeated his experiments on larger animals, as dogs, he perceived this class of movements to be indubitable.

Having trephined the frontal bone, without injuring the dura mater, he distinctly saw an alternate pulsation of the brain coincident with the systole and diastole of the blood-vessels. In the first dog he counted 68 movements of the brain in the minute, and 68 pulsations of the crural artery; the respiratory thoracic movements being only 24. In a second dog he saw 80 pulsations of the brain and crural artery, to 20 respiratory movements. In both there was a cerebral movement also in correspondence with the respiratory, being in the first dog 24 in number, in the second 20. Those movements were quite distinct from the arterial, and strictly proportionate to the intensity of the thoracic respirations.—*Gaz. Méd.*, No. 30, 1848.

PATHOLOGICAL CHEMISTRY.

NEW METHOD OF DETECTING THE PRESENCE OF SUGAR IN THE BLOOD.

M. Rayer, at the suggestion of a young chemist, M. Bernard, submitted the serum of diabetic blood to the process used by the excise to determine the proportion of sugar in molasses, which consists in the admixture of the tartrate of copper dissolved in liquor potassæ. If a small quantity of diabetic serum is placed in a glass tube, with an equal quantity of the above solution, which is of a blue colour, and the mixture be cautiously boiled for a few minutes, the presence of sugar is detected by the conversion of the blue into a brick-red colour, with, at the same time, a precipitation of the oxide of copper.—*Annales de Thérapeutique*, Sept., 1848.

PRACTICAL MEDICINE.

HICCUP TREATED BY INHALATION OF THE FUMES OF AMMONIA.

Two patients were admitted into La Charité for different complaints, but in both of whom hiccup was a prominent and troublesome symptom. M. Rayer immediately applied a piece of sponge, dipped into diluted liquor of ammonia, to the internal fauces, when the convulsive action of the diaphragm ceased as by a charm.—*Ibid.*

SURGERY.

APPLICATION OF THE SUBCUTANEOUS SECTION TO THE TREATMENT OF LIPOMA.

M. Bonnet treats fatty tumours upon the above plan with success. He first introduces a sharp-pointed tenotomy knife under the tumour, and then with a probe-pointed bistouri divides the tumour upwards towards the skin, so as to reduce it to several lobules; he then squeezes the tumour so as to extravasate the fatty matter, and leaves it to be removed by absorption. This operation is repeated several times, according to the size of the tumour. No injurious effects have followed in the cases which he reports, but the results have been so favourable that he is induced to prefer the operation to the methods in general use.—*Bulletin de Thérapeutique*, Juin, 1848.

MEDULLARY SARCOMA IN AN INFANT.

Mr. Blaine narrates the case of an infant, aged nine months, who became the subject of this formidable disease. When two months old, a lump the size of a pea was observed at the inner part of the right thigh; six weeks after a second tumour appeared in the corresponding groin, and the two coalesced; two months after the disease also showed itself in the right shoulder. At the present time the tumour extends completely across the pelvis, involving the right thigh and buttock, the scrotum, and penis. It is tense, elastic, and lobulated; numerous blood-vessels ramify upon its surface. The orifice of the urethra is marked by a slight puckering of the integuments, and the urine is voided with pain and difficulty.—*Med. Times*, Oct. 28th.

[The fearful extent and appearance of the disease is well respresented in a wood-cut. The infant was alive at the time of the report, but was threatened with speedy dissolution.]

OBSTETRIC MEDICINE.

ANÆSTHETIC MIDWIFERY IN AMERICA.

In the first volume of the "Transactions" of the American Medical Association, formed on the same plan as the Provincial Association of England, the report of a committee of members on anæsthesia, &c., in midwifery, is published. Among other matters they state,—"The anæsthetic agents (æther and chloroform,) have now been used in perhaps 2000 cases of midwifery, and so far as the Committee have been able to learn, without a single fatal, and very few, if any, untoward results. The Committee, in a pretty extensive correspondence with physicians in various parts of the country, have found an entire *unanimity* of opinion among those who have tried these agents, as to their favourable effects, both in hastening the progress of the labour, and in relieving the sufferings of the patients."—*Transactions of the American Medical Association*, p. 228.

TOXICOLOGY.

DIAGNOSIS BETWEEN ARSENICAL POISONING AND CHOLERA.

Dr. Letheby has published a very useful communication at the present juncture, on the likelihood of confounding arsenical poisoning with the symptoms

of cholera. The object of his paper will be sufficiently evident in the following extract, giving a synoptical view of the diagnosis:—

Symptoms of Arsenical Poisoning.	*Symptoms of Cholera.*
1. Faintness, but not antecedent purging.	1. Discomfort in the bowels, more or less purging.
2. Great pain in the stomach and bowels.	2. No particular pain in the stomach and bowels; but—
3. Vomiting of dark-coloured matter, streaked with blood.	3. Sudden vomiting and purging; ejected matters, bilious or gruel-like, never bloody.
4. More intense pain, and burning in the stomach and bowels, great thirst and excessive purging; stools dark, and sometimes bloody.	4. Now, pain in the stomach and bowels; great thirst.
5. Skin at first hot, and circulation excited; extremities then cold and livid; tongue retains its warmth and redness; eyes frequently blood-shot; aspect of the countenance not death-like.	5. Skin has not been hot nor itching, but cold and livid; breath cold; tongue cold and blue; countenance pinched; eye glazed and blood-less.
6. Analysis of urine and vomited matters furnishes evidence of poisoning.	6. Analysis of urine [when obtained, Ed. *Prov. M. S. Journ,*] will not yield traces of poison.

Pharmaceutical Journal, Nov., 1848.

THE MEDICAL AND CLERICAL WIDOWS' AND ORPHANS' ANNUITY SOCIETY AND BENEVOLENT FUND.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

A project is in contemplation, which has already been submitted to, and approved by a great number of the profession, to establish a Society with the above designation. According to the views of the projectors the professional Association is to have a two-fold object.

First—The granting Annuities to the Widows and Orphans of Members of the Medical and Clerical Professions exclusively, and on a strictly mutual principle.

Second—The providing a superannuation fund for the benefit of members of the two professions incapacitated from the pursuit of their avocations by casualty, infirmity, &c.

After a most careful investigation of the subject, it has been satisfactorily shown to those gentlemen to whom these proposals have been submitted, that the principle of investment, as applied to annuities, admits of a larger compensation to recipients than the ordinary principle of Life Assurance does, where the payment is made in one sum, at the decease of the assured.

The society proposes granting annuities to widows and orphans in a sum commencing at £15, to be increased annually until it reaches £20, at the rate of £1 per annum for each annuity. Members may subscribe for six such annuities, not more than three to be granted to any one nominee, but no annuity to be claimable until after five years payments of premiums shall have been made.

Annuities to widows to cease on their re-marrying, but to become again payable, should widowhood again occur. In the case of female orphans, annuities to cease on their marriage, but to accrue again should they become widows. Annuities to male orphans to cease on attaining their majority.

An entrance fee of two guineas, with an annual subscription of not less than £1. 10s. for each annuity, to constitute a member, besides a small sum payable for disparity of age between the member and his nominee, according to tables to be especially constructed for this Society.

The Superannuation Fund to be composed of subscriptions of not less than one guinea per annum, entitling the member under a given scale to a pension of from £20 to £30 per annum, in the event of such member becoming incapacitated from pursuing his profession, and provided he should possess no other adequate means of support, and shall have been a subscriber for five previous years.

In the formation of a "*Benevolent Fund,*" to which the higher and wealthier members of the two professions is more especially directed, it is hoped such patronage may be obtained as will at once place this Society beyond competition; and whilst we beg to remind them that the object of the society is to save from penury men who have honourably struggled for themselves, and in times of comparative prosperity have been willing to assist others, we doubt not it will meet with that support to which it is so eminently entitled.

In conclusion, we unhesitatingly affirm, although so greatly needed, that there exists no association of a provident character, embodying the principles of the present society, at all commensurate with the wants of the profession, or sufficiently comprehensive in its operations, as at the same time to entitle its members to its collective privileges as a vested right, and thereby obviating the humiliating alternative of their becoming, in the event of adversity, suppliants for the bounty or charity of the public.

It only remains to be added, that the foregoing project emanates from no professional party, is dictated by no selfish views, but is open to every member of both professions to come forward and take a part in its management, or to give suggestions for modifying its principles or organization. A sufficient number of persons already acquainted with the above details, have expressed their acquiescence and readiness to co-operate in its establishment, so as to give a fair warrant of success.

Any of your readers who will forward his name to "Philo-Medicus," at Bulgin's, 221, Regent Street, will have a personal invitation to a preliminary meeting shortly to be convened, and which will be duly advertised.

London, 10th November, 1848.

SPASMA GLOTTIDIS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I had marked for reply, several passages in Dr. Wardell's last letter on "Spasma Glottidis," but the tone and temper of his remarks are such, that though still unconvinced by his reasons and authorities, I think it best to close our correspondence, which has become too personal to be interesting to the bulk of your readers, particularly as it is evident, from Dr. Wardell's assertion—that the question between us is, "whether inflammation in the throat always is the cause of laryngismus,"—that he has misunderstood the whole tenor of my observations; and hence I am not at all surprised, that Drs. Williams and Walshe should have replied in the affirmative to the enquiry whether they had seen cases of non-inflammatory spasm of the glottis in the adult.

In taking my leave of Dr. Wardell, I would request him to re-peruse my last letter, and then to decide in *foro conscientiæ*, how far he or I have "wittingly passed over certain facts and considerations that are hostile to our views."

I will take this opportunity of pointing out to Dr. Ranking, whose remarks, (quoted by Dr. Wardell,) were published in his "Abstract" before my last letter, that I therein expressly excluded hysterical cases, or such as I conceive he alludes to, by the expression "cases of reflected uterine irritation," in asserting my doubts of the existence of pure uncomplicated spasm of the glottis in the adult. Violent attacks of globus hystericus, severe fits of choking, and the troublesome effects of a relaxed uvula, are really instances of spasm of the glottis in the adult, and sometimes while they last, are attended with stridulous breathing, yet I doubt whether they are identical with this disease in the infant; and I repeat, that it was upon this ground that I objected to the cases of Dr. Wardell, Mr. Alford, and Mr. Gorringe, as presenting more of an inflammatory than of a purely spasmodic origin; hence, to quote my last letter, "without denying the possibility, I must repeat, that Dr. Wardell has not proved the existence of the disease in the adult such as we have it in children."

I am, Sir,

Your obedient servant,

T. OGIER WARD, M.D., Oxon.

Kensington, November 17, 1848.

NOTICE OF DR. MAYD.

At Withersfield Rectory, Suffolk, on the 28th of September, aged 88, died John Winslow Mayd, M.D., for upwards of fifty years a resident at Epsom, during the greater part of which time he was a general practitioner. Latterly he took the degree of M.D., and for some years being incapacitated for practice by chronic rheumatism and failure of sight, he had been in complete retirement.

He was deservedly eminent in his town and neighbourhood for great medical penetration and experience; his natural good sense, and strong sagacity which, with excellent judgment in the diagnosis and treatment of disease, rendered his opinion and advice most acceptable to his patients. He was decidedly, and in every sense of the word, a successful practitioner.

He had good scholarship, and various knowledge; the expression of his opinions and sentiments always candid, and sometimes caustic or facetious, rendered him a favourite with his contemporaries, and the recollection of these characteristics remains in the memory of surviving friends.

In the year 1812, Dr. Mayd, in conjunction with the late Dr. Hardwick, Mr. Wallace, of Carshalton, Mr. Stedman, of Guildford, Mr. Martin, of Reigate, and other friends, established the Surrey Benevolent Medical Society, of which he was the first President, and he rendered essential service in promoting the augmentation of the fund.

NOTICE OF DR. TWINING.

Died, on the 15th inst., aged 35, at 13, Bedford Place, Russell Square, William Twining, M.D. This young and promising physician is another to be added to the list of those who have fallen victims to their thirst for the acquisition of knowledge. Dr. Twining received his education at Rugby, under the celebrated Dr. Arnold, and such was his eagerness to attain distinction, that he overtasked his strength, and laid the foundation of that cerebral disease which has thus prematurely cut him off. From Rugby he went to Balliol School, Oxford, and it was his wish, on more than one occasion, to compete for honours, but his strength was unequal to the exertion. His medical studies at St. Bartholomew's, were pursued with equal ardour, and even when his feeble health rendered such application improper, he was constantly to be found engaged in the perusal of abstruse works in German and other languages.

Dr. Twining held the appointments of Physician to the Farringdon Dispensary, and the Public Dispensary, until compelled by ill health to resign them. He was, in 1841, one of the founders of the North London Infirmary for Diseases of the Eye, and the fervent manner in which he supported that charity, will ever be held in grateful remembrance. In him the unfortunate cretins of Switzerland have lost a firm and zealous friend: not only did he by his pen, advocate the cause of those unhappy outcasts, but he contributed most liberally to the admirable institution for their relief, conducted by Dr. Guggenbuhl, on the Abendberg, near Interlachen.* Active benevolence was, indeed, a prominent feature in his character: he was ever as ready to assist the poor with his purse as with his advice, and many have been the wretched objects who have been restored to comfort, as well as to health, through the unassuming philanthropy of Dr. Twining. Upright, honourable, and unflinching; amiable in disposition, and sincere in friendship; of learning, accurate, varied, and extensive, he had drawn around him a large circle of friends, by whom his loss will be long and deeply lamented, but by no one more than by him who pens this tribute to his memory.

* Dr. Twining's exertions on behalf of the cretins of Switzerland, and the idiots of our own land, have been attended with the happiest effects. There have already been three institutions established for the education of idiots,—namely, at Highgate, at Bath, and at Wells.

Medical Intelligence.

APPOINTMENT.

Mr. Joseph White has been elected resident surgeon to the Nottingham General Hospital, in the room of Mr. Sibson, resigned. A vote of thanks and a well-merited testimony to the high talents and services of Mr. Sibson were awarded on the occasion.

ROYAL SOCIETY.

A warm contest is likely to take place for the Secretaryship of this Institution, about to become vacant by the resignation of Dr. Roget. Professor Thomas Bell and Mr. Grove are the candidates.

UNIVERSITY OF LONDON.

SECOND EXAMINATION FOR THE DEGREE OF BACHELOR OF MEDICINE—1848.

Examiners.—Physiology: Dr. Carpenter, F.R.S.—*Surgery:* Sir Stephen L. Hammick, Bart., and Cæsar H. Hawkins, Esq.—*Medicine:* Dr. Billing, F.R.S., and Dr. Tweedie, F.R.S.—*Midwifery:* Dr. Rigby.—*Forensic Medicine:* W. T. Brande, Esq., F.R.S., Dr. Pereira, F.R.S., and Dr. Rigby.

First Division.—Copeman, Arthur Charles, King's College; Drury, James Samuel, Adjoining St. George's Hospital; Evans, John Owen, University College; Gill, Walter Battershell, King's College; Habershon, Samuel Osborne, Guy's Hospital; Hassall, Arthur Hill, Royal College of Surgeons in Ireland; Hooper, Daniel, Guy's Hospital; M'Crea, William, St. George's Hospital; Palmer, Edward, University College; Payne, Arthur James, King's College; Savory, William Scovell, St. Bartholomew's Hospital; Shelley, Hubert, Guy's Hospital; Sibson, Francis, University of Edinburgh; Wilks, Samuel, Guy's Hospital; Woodforde, Wm. Thos. Garrett, University College.

Second Division.—Jago, Frederick William Pearce, London Hospital; Lang, Henry, University College; Pyper, Robert Deverill, Middlesex Hospital; Ryan William, Middlesex and Jervis Street Hospitals; Sankey, Wm. Henry Octavius, St. Bartholomew's Hospital.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, November 16th:—Thomas Dale, Liverpool; George John Hinnell, Bury St. Edmunds; William Sedgewick; Edward Francis Fussell, Warminster; William Britton Pearce, Mevagissey, Cornwall; E. Austen Steddy, Chatham; Abel Crompton, Crompton, near Oldham.

OBITUARY.

Died, November 2nd, at Newmarket, aged 59, Robert James Peck, Esq., Surgeon, a Member of the Council of the Provincial Medical and Surgical Association.

November 6th, at Southampton, aged 29, John Alfred Stace, Esq., Surgeon.

November 11th, at Boulogne, aged 69, John Hill, M.D.

November 11th, at Dublin, aged 91, ——— Renny, M.D., late Director-General and Chief of the Army Department in Ireland.

November 13th, at Shrewsbury, aged 82, Robert Waring Darwin, M.D., Consulting Physician to the Salop Infirmary.

November 17th, at Brighton, aged 57, Thomas Callaway, Esq., Member of the Council of the Royal College of Surgeons, and for many years Assistant Surgeon to Guy's Hospital.

November 18th, at Shadwell, of fever, David Burn, Esq., Surgeon, Officer of Health under the Nuisances Removal Act of the Stepney Union.

Lately, Carlo Francisco Bellingeri, M.D., President of the Medical Faculty in the University of Turin, &c., well-known by his works in support of Sir Charles Bell's "Researches on the Nervous System."

Lately, William Henchman Crowfoot, Esq., F.R.C.S., Consulting Surgeon to the Beccles Dispensary, and a Member of the Council of the Provincial Medical and Surgical Association.

BOOKS RECEIVED.

Elements of Anatomy. By Jonas Quain, M.D. Fifth Edition. Edited by Richard Quain, F.R.S., and William Sharpey, M.D., F.R.S., Professor of Anatomy and Physiology in University College, London. Part III. London: Taylor and Walton. 1848. 8vo.

Physiological, Anatomical, and Pathological Researches. By John Reid, M.D., Fellow of the Royal College of Physicians of Edinburgh, &c. &c. Edinburgh: Sutherland and Knox. 1848. 8vo, pp. 659. Plates.

On the Treatment of Asiatic Cholera. By Archibald Billing, M.D., F.R.S., &c. London: Highley, 1848. pp. 15.

Cholera: Practical Observations on a Successful Method of Treating Cholera. By Charles Patterson, M.D., Physician to the Rathkeale Infirmary and Fever Hospital, &c. (From the *Dublin Medical Press.*) Dublin: Hodges and Smith. 1848. 8vo., pp. 8.

Report of the Medical Officers of the Lunatic Asylum of the County of Lancaster. 1848. 8vo., pp. 22.

The Transactions of the American Medical Association. Vol. I. Philadelphia. 1848. 8vo., pp. 403. Plates.

Tracts for the Improvement of Medical Literature. No. III. London: Churchill. 1848. pp. 80.

The Objects of Medical Study, &c. By W. B. Carpenter, M.D., F.R.S., F.G.S., &c. (From the *London Medical Gazette.*)

Memoranda on Poisons. By T. H. Tanner, M.D., &c. London: Renshaw. 1848. 32mo., pp. 63.

Illustrations on the Fraud and Folly of Homœopathy. By Jonathan Toogood, Extra-Licentiate of the Royal College of Physicians, Fellow of the Royal College of Surgeons, &c. &c. London: Churchill. 1848. 8vo., pp. 26.

TO CORRESPONDENTS.

Communications have been received from Dr. C. W. Bell; Mr. W. W. Cooper; Dr. T. O. Ward; Dr. E. T. Roe; Mr. Sloman; Mr. T. Martin; Philo-Medicus; Dr. Syme; Professor Simpson; B. A.; Mr. T. N. Bradley; Dr. Carlyon; Mr. T W. Crosse.

We have been unavoidably compelled to postpone a notice of the Manchester School of Medicine, as well as several other communications to which we hope to give early attention.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

LECTURE ON THE NATURE & TREATMENT OF CHOLERA,

CONSIDERED WITH REFERENCE TO ITS

ANALOGY WITH CONGESTIVE AGUES OF QUOTIDIAN TYPE.

By Charles W. Bell, M.D., K.L.S.,

Physician to the Manchester Royal Infirmary, &c., late Physician to Her Majesty's Embassy, in Persia, &c., &c.

(Read before the Medical Staff of the Manchester Royal Infirmary, and the Members of the Medical Profession in Manchester, November 3rd, 1848.)

Lecture II.

Gentlemen,—

The object of my former lecture was to show that cholera is not a disease *sui generis*, but one of a large class produced by malaria;—that, operating on the individual, either by some agency with which we are unacquainted, or by a poison carried by the blood, its cause does not directly affect the blood itself, and is not capable of reproducing itself in the blood by the elaboration of fresh poison in the system, like that of contagious fevers;—that no poison is extricated from the blood by special emunctuary action, like that of small-pox and scarlatina, which is capable of giving rise to the same disease in another by inoculation or by infection;—but that diseases of this class are all incommunicable from man to man, and as there is no remedial object accomplished by the morbid action, and no noxious poison removed from the system, there is necessarily no crisis and no natural termination; and so far from disease of this class conferring immunity from subsequent attacks, one of its chiefest characteristics is a tendency to relapse, and to render the patient more, rather than less, amenable to the influence of the same impression for the future. Not being like that of exanthematous fever, (a poison which produces disease in the blood itself,) the cause of this class of disease does not operate as a source of continued irritation to the whole system, so as to produce continued fever, but on the contrary, acting in a manner directly opposite, it induces diminished irritability of the system, instead of irritation, causes depression, instead of excited action of the vital powers, and when fever succeeds, it is that of mere reaction against an impression opposed to vitality, not a struggle to rid the system of a source of irritation which proceeds unintermittingly towards the accomplishment of an end. When, in continued fever, the digestive and cerebro-spinal functions become disordered, they do so in consequence of an all-pervading source of irritation, and in conjunction with excited circulation; but in the class of diseases under consideration, we observe the effects displayed in the digestive, the cerebro-spinal, or the respiro-circulatory functions, separately, or in either two combined, in conjunction with depressed circulation.

In continued fever, death occurs either in consequence of organic disease and change of structure in some vital organ, or from the effects of poisoned blood upon the brain; but in the class of intermittents, the brain is the last to die, death taking place in consequence of mere disordered function of the vital organs, without organic change of structure.

These wide distinctions between the effects which we know to be produced by the circulation of diseased blood in contagious fevers, and those which follow the impression of the unknown cause of epidemic diseases, led us to the conclusion that the phenomena displayed in the latter class, were inconsistent with the belief that actual change in the constitution of the blood could possibly be their cause; and if not on the blood, it is quite evident that whatever produces these effects, must operate on the sympathetic system of nerves, for only the sympathetic and the blood are distributed co-extensively with the effects observed.

We showed reason to believe, that in every disease of this class, the first effect of the unknown cause is an *impression* on the sympathetic, which impairs its power of exciting, regulating, or combining the functions of those vital organs whose unity of action is necessary to life; and that this impaired vitality or disturbed function of the sympathetic, is variously evinced by derangement of the functions, in whole, or part of the circulating, digestive, and cerebro-spinal systems, either separately or combined.

It was argued that, great as the changes are that take place in the appearance and quality of the blood, during a fit of cholera, this does not at all militate against the above conclusions, for these changes are not primary effects of poison on the blood, but secondary effects of functional derangement in the pulmonary and systemic capillaries, by which the blood is prevented from undergoing the processes necessary to its healthy condition, and to the maintenance of its vitality. It is only in consequence of cessation of such changes that the blood in these diseases loses its florid colour, its fluidity, and its vital property of forming a

firm coagulum as it dies, for it has been observed that blood drawn during an attack of cholera, as well as that taken from the body after death, shows all the wonted disposition of healthy blood to absorb oxygen from the air; and when we practise bleeding successfully in a severe case of cholera, and thereby restore the patient to immediate health, we find that the blood which at the first was dark, tarry, and adherent to the wound, and made to flow with the greatest difficulty, presently runs more and more freely, and before we bind up the arm we see it acquire all the characteristics in colour, fluidity, and free uncontrolled motion through the vessels, which belong to healthy blood. It is obviously impossible, that by simple removal of a portion of the blood, all the dread poison on which so many authors of repute insist, can be removed from the whole mass of the blood, along with this small quantity; on the contrary, this is rather an *experimentum crucis*, to show that restoration of the functions of the minute circulation in the lungs, and throughout the system, is the cause of the immediate restoration of the blood to its natural condition, which had been altered only by the cessation of these functions.

Having thus endeavoured to prove that the disorder is not originally, but secondarily, in the blood, and therefore that the primary cause must be morbid impression on the sympathetic nerves, we proceeded to consider the great characteristic of this whole class of disease,—viz., periodicity of attack, and attempted to explain periodicity by the law of nervous impression,—viz., that long continued impression on a nerve of sense subdues its sensibility, and that change of impression restores it, endeavouring to show that when disorder is induced by morbid impression in one part of the circle of vital actions, the derangement of action which results in other associated organs produces a new impression on the nervous system, calculated to counteract the first, and restore to the nerve the power of being excited by its natural sensibilities in all its varied functions.

Having then shown that the first stage of disease is alike in ague and in cholera, it was argued that they are alike subject to the same effects or law,—viz., periodicity of action. Such was the theory of the disease then offered to you. Practically it was shown, that in ague and in cholera, the morbid impression always evinces itself first in apparent cessation of vital action in the capillary circulation, more or less general, and more or less complete, by a greater or less approach in the condition of these vessels to that of inanimate tubes or dead structure; that the vital changes on the blood in the terminal capillaries then cease, animal heat is not evolved, the blood instead of coursing freely through the minute veins, adheres to their coats, and instead of remaining fluid, assumes a half-coagulated condition, as if the interior coats of the vessels had lost a portion of their known power to maintain its fluidity; that the veins, instead of being gently distended, contract, as in death, and reject their contents. Such was considered the first condition of the cold stage.

It was then shown that the direct effect of this first condition, and of the continued rejection of the blood from the capillary circulation, is its accumulation in the great sinuses and venous organs of the chest and abdomen, oppressing the action of the right side of the heart, deranging the circulation, and impeding the functions of the principal vital organs, and diminishing the quantity of arterial blood distributed to every part of the body; therefore, as upon this the life of the whole body depends, destroying vital action, and causing collapse and death.

But to this fatal effect of derangement of the capillary circulation and consequent congestion, it was shown that the system does not always submit without a struggle, although such is the history of those almost instantaneous deaths from cholera sometimes met with; on the contrary, when from the above cause the cavities of the heart and spleen are distended, (for I believe the spleen, with its sympathetic plexus and elastic structure here plays an important part,) the immediate effect is that produced by the distension of any hollow muscle,—viz., a stimulus to contraction. This becomes a source of excitement to the nervous energy of the heart, and through it to the sympathetic, in all its functions, and among others, to the resumption of its power over the capillary circulation.

It was shown that in ague the commencement of re-action is evinced in general convulsive shivering of the whole frame, then by fever, and then by return to natural action; but that in cholera the heart seldom experiences relief by simple re-action, without some mechanical aid to diminish the quantity of the blood thrust upon it from the extremities; that this is effected either artificially by bleeding from a vein, or naturally, by the exudation of the watery part of the interior blood into the mucous or serous tissues. It was stated that this mode of relief commonly, but not always, takes place from the intestines, by the watery diarrhœa of cholera, and is then either sufficient at once to relieve the circulation, and conduce to complete cure, or if insufficient for complete cure, it may be adequate to prevent the immediate death which would result without this relief to the congestion, and thereby permit the disease to reach its secondary stages; or, third, failing both these methods of relief, the power of the heart succumbs to the oppression, after which the morbid impression, unopposed by circulation of arterial blood, attacks the cerebro-spinal system, and terminates the struggle in convulsion.

Lastly, attention was invited to the fact that cholera, like congestive ague, has its diurnal periods of accession and remission,—that, therefore, extreme caution is requisite to avoid attempting to give relief at all times by the same means; for bleeding, which will relieve all the symptoms in the first hours of an attack, will produce the very opposite effect some hours later, unless we wait for the commencement of the new accession, when it will be equally applicable as in the commencement of the first attack.

It was also thrown out as a suggestion worthy of inquiry, whether cholera does not follow the course usual in quotidian agues,—namely, a tendency to run a course of three days' repetition of congestion, where

death or cure does not interfere, for in that case the return of the congestive stage will not be so much to be dreaded on the fourth day as consecutive fever.

In dwelling upon these points I was not so presumptuous as to hope that you would receive any one of them solely upon my individual statement, or even consider them proved by the arguments adduced. My intention was rather to state them as points, which, after much reflection and study of the subject, both in its general features and in individual cases, appeared to me to be those to which it was most important to direct attention both in reading and in practice; because, if we are convinced that the disordered action begins in the capillary circulation,—that the congestive stage and symptoms are direct consequences of this disturbance,—that this condition is not absolutely persistent throughout the whole attack, but goes through certain diurnal changes,—and that the general tendency is for the congestive stage to return on three successive days, and afterwards to run into more continued febrile action, we shall then have a clearer perception of what is wanted in respect of treatment at each particular stage of the disease, and can adapt our remedies accordingly; and from knowing what to expect, we are enabled to distinguish the effect of the remedies from that of the disease they were intended to combat.

I am aware that by many the theory of the disease may be considered to have been unnecessarily dwelt upon, especially in that part of it which attributes the effects to morbid impression on the sympathetic, but this appeared to me important with regard to diseases associated with cholera, and in reference to the *modus operandi* of medicines which are found to exert a beneficial influence, in very different, and apparently very opposite, conditions of the system, arising from the same malarious influence.

I have stated it to be the object of the present inquiry, to search for some enlarged principle for our guidance in the treatment of cholera, which the observation of individual symptoms only tends to confound; and it seemed absolutely necessary, before considering the means employed for cure, to inquire, as carefully as possible, into the essential nature of the malady, in order to comprehend distinctly the intention to be kept in view in administering medicine.

CONNECTION OF CHOLERA WITH OTHER EPIDEMICS, AND THE INFLUENCE OF ITS CAUSE ON THE CONSTITUTION.

We have hitherto considered the malarious influence by which ague, cholera, and remittent fever are produced, only in its physiological effects on the human body, with little reference to their epidemic character, and without attempting to fathom the origin or nature of the cause. The cholera atmosphere, as it has been termed, is generally believed to pervade chiefly the lowest levels of a tract of country, and I believe this to be correct; but it is singular, that one of the spots pointed out to me as most fatal in Persia, was elevated 10,000 feet above the level of the sea, another 8000, and another 5000; it is also said to follow chiefly the courses of rivers,—in Persia it has uniformly been most fatal in the neighbourhood of the extinct volcanoes which crown the great range that extends from Ararat to Khorasan. Dr. Prout observed, that during the prevalence of cholera, the atmosphere was perceptibly heavier than at other times. In 1834, it was observed in the great London breweries, while cholera was at its height, that fermentation proceeded more rapidly than was usual, and of late an attempt has been made to connect it with certain remarkable electrical phenomena. Dr. Prout's observation has been verified, that during its prevalence a greater than usual tendency exists to the formation of oxalates in the urine. In both its invasions of Europe, its progress has been very remarkable, and not in the direct commercial route from India, having in its first advance adhered steadily to a course nearly W. NW. from Hindostan; and its second was nearly identical, but with greater extension of its left wing, towards the south.*

Not only to medical men, but to the Government of every country through which cholera has passed, its progress has been a subject of great interest in reference to the question of contagion, ever since its first recorded outbreak in Lord Hastings' army in India, in 1817. But although none of the well-contrived barriers opposed to its advance by *cordons sanitaires*, or quarantine regulations, have yet succeeded in delaying its march a single hour, the question is not yet settled. The facts just alluded to all display the general pervasion of something unknown, which influences the physical as well as the animal world, but is wholly beyond the power of man to stay; and, did time permit, others might be added still more convincing, bearing upon the change observable in the features of disease, both in the animal and the vegetable kingdom, long before the actual appearance of cholera. If, then, the connection

* Without attaching much importance to facts which cannot explain the progress of cholera in other directions, I may mention as a contribution to its history in central Asia, that its first advance upon Persia in 1828-9 was preceded by terrific earthquakes in 1827-8, extending for some hundred miles around the extinct volcano Demawund; that there then succeeded a period of repose from subterranean convulsion till 1840, when a violent earthquake shook down a portion of Mount Ararat, and continued to convulse the country to the south-east of that mountain till December, 1843, when, for the first time in the historical period a new volcano burst out near Shoomacha, thirty miles to the west of the Caspian and perhaps a hundred to the north of Ararat. That in 1841-2-3 the whole tract of country between the mouths of the Indus and the Caucasus had been overrun with unaccustomed dysentery, pestilential fever, and in some places cholera, but after this eruption earthquake ceased and the country became comparatively healthy till 1846, when cholera again broke out with virulence in the same tract. Since then, the main line of the advance of cholera has been in the direction of the volcanoes of Iceland. I leave it to philosophers to determine how far it is possible that extensive chemical action beneath the thin crust of this earth, evinced by these earthquakes, may have had anything to do, either by disturbance of electrical currents, or the evolution of imperceptible gases, in producing so great an amount of disease, and in determining the main direction of cholera over the line of country which evidently overlies an immense volcanic tract, that extends in a direct line from Cutch, late the scene of extensive subterranean disturbance, over the Elboorz and the Caucasian mountains, towards the principal volcano of north western latitudes.

of these facts with cholera were better determined, and collected, it seems to be impossible to doubt, that the evidence of the existence of a cause, infinitely more general than mere contagion, would soon prove so conclusive as to set the question at rest for ever.

These are points, however, far beyond my depth, and foreign to our present object, which is practical observation of the facts which indicate the relation of cholera to other diseases, and to inquire what useful inferences may be deduced from them.

With respect to the epidemic influence of the cause of cholera in this country, a great change in the character of disease must have been remarked by the elders of the profession since its first advent; and it is notable to younger practitioners, that there is an obvious difference in the practice of the generation of physicians which is now passing from among us and their own,—those of the old school are much more stringent in the article of diet, more cautious of the use of stimulants, and altogether much more apprehensive of inflammation, than we of more modern days; it is also notorious, that tonics are now much more universally prescribed than they were five and twenty years ago. All this is attributed by some to *fashion* in medicine, but it is evidently not so. In the commencement of the present century, the prevailing fever was attended with high arterial action, and the more acute forms of inflammation were much more general, insomuch that the lancet, calomel, and antimony, were then the sheet-anchors of the practitioner; but since a few years previous to the first inroad of cholera, a great change has occurred, bleeding in fever is now almost obsolete, a much more generous diet has become necessary, and calomel is comparatively disused. Since 1843, the type of sporadic fever of this country has approached more nearly to that of the remittents of tropical climates, displaying an unusual tendency to relapse and to local congestions. Neuralgia has also greatly increased; and Bright's disease, and dropsy after scarlatina, &c., become more general. This particular type of fever has pursued so remarkable a course, that before submitting to you the account of the various forms in which it appeared in Persia in 1842-3, when obviously and essentially connected with cholera, I think it of some importance to trace its progress from India to this country, great part of which I have myself had the opportunity of witnessing.

In 1841, a fever of remittent and quotidian intermittent type broke out in Scinde, where it destroyed many of our best troops, alternating occasionally with cholera. Both proved severe in Caratchee: it spread through Beloochistan, and appeared at Bunder Abbas in the Persian Gulph, early in 1842; also at Yezd. It thence spread westward to Shiraz, and northwards towards Ispahan and Tehran, proving everywhere extremely fatal; but its further progress to the northwest was arrested for a time, on the high grounds of Sultanieh, by the setting in of winter. Next spring it resumed its course, overspread Aderbijan, Erivan, Georgia, and the whole shores of the Caspian, crossed the Caucasus, and was very fatal in Veronish in the centre of Southern Russia. I here lost sight of it in November, 1843, but was not a little surprised to find it again in December, on my arrival in Edinburgh. It was there modified it is true, and displayed less of an intermittent character, but was fully characterized by other symptoms, especially the tendency to relapse, and the pale tongue. Late in 1844, it appeared in Manchester, especially in Ancoats, where it was very severe. In 1845, it became epidemic in Liverpool, somewhat more modified in type, and the fever of 1846-7 in Manchester, still preserved much of its peculiarites, especially in the frequency with which it was accompanied with jaundice, and in running a course of seven, fourteen, or twenty-one days, and relapsing at these intervals.

For nearly two years, the typhus fever imported from Ireland has rendered this type somewhat obscure, but within the last few weeks, beginning in the middle of September, the same form of fever has become again prevalent and very severe. This will suffice to shew that not only cholera has spread to us from the east, but that since its arrival the very constitution of our fevers has partaken of a similar oriental character, and that not fashion but necessity has demanded the remarkable change of practice alluded to. The best evidence that this is not an *imported* change is to be found in those fevers which arise sporadically from the decomposition of vegetable matters, for these always assume the character of the epidemic then prevailing; as when plague broke out in Oxford, caused by a collection of putrifying cabbages, in the reign of Charles the II., and the most exaggerated form of the type of fever we are now considering appeared in a farm-house in Peebleshire, in 1846, caused by the decomposition of stable manure; so cholera generally makes its first apearance in the neighbourhood of cesspools, and in the most filthy parts of a city, and judging from my own experience, I should think that ague of a quotidian type must have been remarked by many within the last three years in badly-drained houses. But it may be remarked, that the epidemic constitution of disease is not only displayed in the fevers of a country, but equally so in every aberration from health, and ever since the first appearance of cholera in this country, these have been such as to require a much more extensive use of tonic medicines. In proportion as the lancet has fallen into disuse, iron has come into vogue in another shape, for although seldom prescribed five and twenty years ago, except for chlorosis, in the form of Griffiths' mixture, the greater proportion of diseases are now treated with chalybeates, a perfect evidence to my mind, not of the influence of fashion, but of necessity, and offering, I think, good grounds for attributing to iron some especial influence over the effects of the prevailing epidemic constitution in this country. For, whereas, thirty years ago this was marked by a highly inflammatory tendency, what we have now chiefly to combat, is feeble and imperfect arterial action, and a great and general disposition to venous congestion, not only in fever but in other diseases.

The usual indication for the use of iron is a pale tongue, and this is a special characteristic of cholera,

also in quotidian intermittents and remittents, at particular stages. Its *modus operandi* is generally considered to be to increase the facility with which oxygen is absorbed by the blood, thereby aiding its transmission through the pulmonary circulation, preventing congestion on the right side of the heart, increasing the vitality of the arterial blood, and promoting capillary action in general, but it would also appear that iron exerts a peculiar, and perhaps independent, tonic influence on the nervous system ; hence its effect in tic-douloureux, sciatica, and spasmodic affections, such as hysteria and chorea. Its use as an opponent to mercury is pretty well known, and in moderating congestion, and regulating secretion, in menorrhagia, amenorrhœa, and Bright's disease, while its wonderful effect on spleen disease produced by ague, is well known to East Indian practitioners. These considerations, which would each admit of extended comment, will serve as an introduction to what I have to say of my experience of its effects in the epidemics I have now to describe, beginning in forms very different from cholera, yet ending in that disease, and while their history will demonstrate their near connection with cholera, it will also exhibit the singular effects of iron in various disordered conditions of the nervous system produced by malarious influence, and in restoring their appropriate action to medicines whose operation had been disturbed by the same cause, especially that of purgatives on the intestines, and of quinine on the capillary circulation in general as an antiperiodic.

In our present ignorance of the *modus operandi* of medicinal agents, the efficacy of iron in counteracting deranged action produced by malaria in the several systems,—nervous, circulating, and digestive, over which the sympathetic exercises its controlling and combining influence, will be looked upon as little more than a curious fact, but as all the diseases I am at present about to bring to your notice occurred in a single year, between January, 1842, and January, 1843, the fact of iron having been found influential in all, must necessarily be taken as strong evidence of identity in the cause of those diseases to which it proved an antidote, and therefore strongly presumptive of a closer connection between tetanus, neuralgia, remittent fever, ague, and cholera, than is generally admitted.

The circumstance which first drew my attention to iron as an opponent to venous congestion, and to mercury, was a severe case of spleen fever, with much cerebral excitement; the symptoms were not such as to induce one to trust to a tonic medicine for the cure, and on the authority of Dr. Abercrombie I treated my patient with calomel, antimony, and salines. He quickly became salivated, an effect as readily produced in spleen disease as in Bright's disease of the kidney. Upon this he got alarmingly worse, fever and delirium increased, and he was only saved by immediate change of treatment to that recommended in Mr. Twining's work on "Diseases of Bengal,"—namely, the combination of sulphate of iron with purgatives. Under this course he quickly recovered from the salivation and fever, and by perseverance for a few weeks the spleen was reduced to nearly its normal size.

As enlarged spleen is the direct consequence of repeated dilatation of the organ by successive fits of aguish congestion, and as subsequent experience showed that purgatives uncombined with iron did not produce the same effects on the spleen, it seems a fair conclusion that the iron operated by opposing the acquired tendency to venous congestion. In my own practice, too, I did not find quinine exert that miraculous effect in diminishing the volume of the spleen which is attributed to it by American and French physicians, and which has been exhibited by experiments on dogs ; on the contrary, it often produced irritative fever, which it never did in combination with iron. The probable reason of this difference in the results is, that I employed it most where the prevailing type of ague was quotidian; others, where the type was tertian, to which the effects of pure quinine seem more peculiarly appropriate.

The next experience I had of iron as a remedy of unexpected power was a very singular form of epidemic disease, that exhibited extraordinary disorder of the nervous system.

A few weeks before this appeared in Tehran a somewhat similar epidemic had prevailed in Bagdad, but there it occurred in the form of angina pectoris, destroying life in a few minutes by spasm of the heart, particularly where any organic weakness existed in the organ, and similar, it may be conjectured, to the attack of which Lord George Bentinck and the corpulent Mrs. Armitage appear to have died.

A notice of the disease in the forms in which I witnessed it, may be found in an extract of a letter from me to my late brother, published in the Twenty-sixth Volume of the "Medico-Chirgical Transactions;" and mention of a similar disease, as occurring in Strasburg in 1842, is made in one of the numbers of the "British and Foreign Quarterly Review."

This disease might be described as an epidemic apoplexy or epilepsy; it was characterized in the slighter cases by sleeping of the hand and foot of one side, coming on periodically every night at a particular hour, and accompanied with palpitation of the heart, nervously excited pulse, and severe headache, but though periodical in its attacks, I could not distinguish anything resembling a cold stage or actual fever. In the graver cases it appeared as coma, with hemiplegia, or epileptic and tetanic convulsions, which, if mismanaged, ended in death, at the same time facial neuralgia was unusually prevalent; in fact there was scarcely a form of nervous disorder which this disease did not assume in the two months during which it continued to prevail.

In two of the earliest cases, misled by acute pain in the knees and shoulders, accompanied with great palpitation of the heart, I mistook it for rheumatism, with commencing carditis, and ordered bleeding, and calomel and opium. By this treatment the symptoms were much aggravated, but they susbequently yielded to repeated doses of iron.

It were difficult to say what induced me to try this remedy, but I fortunately hit upon it early in the disease, and there was not a single case among very many hundreds in which a few doses of iron did not

suffice to effect a permanent cure; whereas quinine, purgatives, blood-letting, and mercury, all did more harm than good, and if uninterfered with, the disease often continued to recur nightly for weeks.

In the treatment of this epidemic, the Strasburg physicians were less fortunate. It does not appear that they had tried either iron or assafœtida, and the conclusion come to when the epidemic disappeared was, that "nothing seemed to do good, but that upon the whole, more of those who were bled recovered than of those who were not."

This strange disease affords a good instance of a malarious poison producing its effects mainly on the nervous system, and a singular example of a disease so grave as to present symptoms which generally accompany only the most serious lesions of the brain, yielding completely and invariably to so simple a remedy as a drachm or two of sesquioxide of iron. There was here no remarkable change in the secretions, save that so long as it prevailed there was a general tendency to constipation, and nervous irregularity of the bowels, which I shall have to remark, as occurring again in a subsequent epidemic. For nearly two months while the disease lasted, I had occasion to observe that the action of purgative medicines was frequently either null, or it was unusually severe; but I soon found, that where I was giving iron at the same time, their effect became regular, and for some time I was obliged to combine iron with every purgative, in order to ensure its action, even in cases where there was no other symptom of the malady present.

After the disappearance of this epidemic in March, the season was unusually healthy, with the exception of a few cases of a low form of apparently continued fever, but I believe really remittent, of the same kind with that which afterwards became epidemic in Edinburgh, in 1843, and which exhibited an unusual tendency to relapse.

In August, having few cases of importance to detain me, I quitted our sultry camp, then perfectly healthy, on an excursion into the Elboorz mountains, and pitched my tent at an elevation of 10,000 feet above the level of the sea, near the summit cone of the extinct, but still smoking, volcano Demawund. I was surprised on my arrival to find the tribes already deserting these celebrated pastures, and moving off to the lower grounds, the reason assigned was, that fever and death were busy amongst them, and that they were fleeing from pestilence. I saw several of the sick, and believed the fever to be the usual typhus of the country, but thought it strange to find it in such a locality.

On my return on the fifth day to camp, I found about a dozen of our attendants ill of fever, one man being in *articulo mortis*, but he had newly arrived from the eastward, from which it appeared that this epidemic was spreading. He died comatose, with a black tongue, and symptoms that I now recognize as those of malarious poisoning, and which similate effusion on the brain,* but which I did not then recognize as such, and believed his fever to be the typhus, such as I had been accustomed to see in the five preceding summers in Persia, for I was not then convinced that eruption is diagnostic of typhus. In the other cases the tongue was thickly coated, all the secretions disordered, and I saw no reason to depart from the routine treatment by calomel, antimony, and salines, which till then had proved successful. None of my patients, however, improved under this system; on the contrary, they were getting worse, and one case seemed rapidly hastening to a fatal conclusion, from excessive vomiting and irritability of stomach.

At this time the Russian Embassy was without a physician, and my attendance was besought for one of the *attachées*, who was suffering from ague, to which, however, he had formerly been subject. Hitherto I had seen a great deal of ague in Persia, but almost always of the tertian type, which very rarely indeed resisted the effect of a few small doses of quinine after a purgative. In this case the first two fits were tertian. I prescribed, and promised immediate cure, but in place of cure the third attack took place on the fourth day, and others on the fifth and sixth, and the tongue became dry, glazed, and cracked, such as I had not seen it before in ague, but very like that which we see in the worst forms of nervous fever, without eruption, now prevailing in Manchester. My patient was encamped by the side of a stream, and under the shade of trees. Conceiving that this might be the cause of the unusual severity of the attack, I had him removed to a house on the top of a hill; still, however, he became worse, the shivering less decided, the fever more prolonged, and the stage of sweating and of intermission more imperfect. It was now rather a remittent or a continued fever, like those in our own camp, than an intermittent; quinine was evidently injurious, and I was hesitating whether to adopt the same treatment, with calomel and antimony, that I was pursuing with the others, when, on examining the præcordia, I found that there was much pain on pressure over the spleen; upon this I determined to try iron, in combination with quinine, and gave him pills, composed of sulphate of iron and quinine, of each a grain, combined with one-third of a grain of aloes, every two or three hours. I entertained, however, but little hope of his recovery, for I then expected the next accession to carry him off; it was, therefore, with no small surprise and satisfaction, that I found him sitting up next day at the hour which I had expected to be his last, and conversing with his friends. The tongue, which had been glazed and dry, and so deeply and painfully fissured as to prevent his speaking, had now become soft and moist, the pulse more free, and the shivering fit, which had been absent for the

* This is identical with the fearfully fatal fevers of the Persian Gulph, which generally prove mortal very rapidly, with symptoms of effusion on the brain; but *post-mortem* examination proves these fallacious, and the only constant *post-mortem* feature is soft and friable spleen. Calomel and bleeding is the usual treatment, death the almost invariable consequence. I can confidently recommend rapidly repeated doses of quinine and sulphate of iron of each a grain, with a drachm of sulphate of magnesia, in three ounces of water, as most efficient in the cure of this much-dreaded form of fever.

last two days, came fairly on, and he was well in a few days.

Returning to our camp full of the new light that had thus broken upon me, as to the nature of the fever which was now destroying hundreds in the neighbouring villages, and spreading with great rapidity, and to which this intermittent was evidently nearly related, I re-examined all my patients, and discovered in all, more or less tenderness in the region of the spleen or epigastrium, and on watching more narrowly distinguished the remittent type, which had hitherto escaped my observation, for I now perceived that all the symptoms became aggravated after three in the afternoon, and that an imperfect remission took place in the morning; that the tongue, which towards evening, and in the fore-part of the night, was dry, black, and coated, was soft and moist in the morning, except in the centre, and the edges pale and translucent. I pursued the same principle of treatment in all, by combining iron with quinine, camphor, aloes, salts, &c., according to circumstances, and adding venesection or leeches to the pit of the stomach in the worst cases, about the time which I judged to be the commencement of the stage of congestion. No sooner was this change adopted than I had the satisfaction of witnessing immediate improvement in all.

I must, here, however, mention the case of one of the table servants of the Embassy, who had for some days been affected with most obstinate constipation. I had given him castor-oil, senna and salts, calomel, calomel and jalap, colocynth, and croton, all in vain—nothing moved his bowels; and, disgusted with my inefficient treatment, he betook himself to the native practitioners in town.

After two or three days spent in the repeated administration of enemata, only one very small evacuation had been produced. I encountered this man on my return from the Russian camp, looking wretchedly ill, and in complete despair. I now remembered my former experience of combining iron with purgatives, and gave him ten grains of jalap powder, with one scruple of oxide of iron, which relieved him perfectly, and afterwards a grain of sulphate of iron, with three of aloes, always operated freely on his bowels.

At the time of which I have been speaking, while my Russian patient was so ill, I was called to see a poor French girl, whose father was a general in the Persian service, and encamped in a damp and thickly-wooded orchard near the town, about seven miles from our tents. She was apparently suffering from dysentery, passing blood and mucus, the skin hot, and pulse about 130. I treated her according to the Calcutta practice as given by Mr. Twining, with ipecacuanha, blue pill, and extract of gentian, in which my experience of the fatal dysentery of the preceding year had given me the utmost confidence. No improvement, however, took place, and it appeared to me that there was no resource but to bleed from the arm, for I had frequently proved the efficacy of venesection even in the most reduced cases of dysentery without meeting with a single untoward circumstance to make me dread its effects; my surprise and dismay were therefore great, when, as soon as a few ounces were drawn, she became faint and collapsed, and the body mottled, blue, and cold. It was only now that I learned by cross-examination of her attendants, that in the first commencement of her illness she had had one or two shivering fits, and since then had each night become extremely cold, but without shivering. I had hitherto unfortunately only seen her in the forenoon, when hot and feverish, and none of the symptoms led me to suspect ague, which was not as yet prevalent. She revived a little by the use of stimulants, and I then left her, being called away to another patient, where I was detained so long that the city gates were shut, and I was prevented from visiting her again that night.

The patient I was called to was a man of some importance, who had been out on a hunting excursion the day before, and had slept by the side of a stream. He was awakened by excruciating pain along the spine and in the chest, so severe that he could scarcely breathe; the pain was now most in the epigastrium, and so acute that he could not bear the slightest pressure; the agony appeared too acute for inflammation, and other evidences of pleuritis and peritonitis were wanting; the skin was warm, and the pulse small, contracted, and very rapid. Much at a loss, I gave a large dose of morphia, and exhausted every means of allaying the pain, with the intention of awaiting further symptoms, but the pain continued to increase until about midnight when the difficulty of breathing became so extreme that I determined to bleed him; blood flowed freely at first, but scarcely had four ounces been drawn when it suddenly stopped, coagulating, black, and tarry on the wound. He instantaneously became blue and mottled, and was seized with terrific tetanic convulsions, bent backwards nearly double in opisthotonos, and in a quarter of an hour he was dead of cholera.

It was not till next morning that I learned that my poor French patient had died at the same hour, with exactly similar symptoms.

The two cases I have detailed were the first of the kind which had occurred, and first pointed to what the epidemic I was dealing with was tending, and made me aware of the fatal mistake I had committed in both; for I had bled late in the hot stage of what might be considered an intermittent, and brought on collapse by the very means which, if used in the antecedent period of commencing congestion, might possibly have insured safety.

I was not mistaken in believing that the epidemic character of disease which now spread rapidly and extensively over the whole district, was but a modification of Asiatic cholera, to which the fresh cases which occurred became daily more and more assimilated, until the various divergent forms for a time merged completely into cholera, as it has everywhere appeared. In all these different forms it was an invariable feature, that if periodicity was to be traced at all, it was always accurately quotidian, and this was the case in a very large proportion of the sick.

I shall not detain you with a detailed account of the various forms of disease allied to cholera which then

prevailed, because I have already published a synopsis of them, in the 32nd No. of the *British and Foreign Medical Quarterly Review* for 1843, under the title,—"Epidemic Ague of Persia, a Species of Cholera." The character of disease was greatly varied, both in intensity and symptoms, appearing as simple tic-douloureux, and intermitting hemicrania; paralysis, general or partial, of every part, and in every degree; in congestion of the brain, simulating apoplexy or epilepsy; in shivering ague, or ague without shivering. By and bye this form was more frequently accompanied with vomiting, purging, and cramps, so as to constitute, in every respect, an intermitting cholera; whereas others had attacks resembling cholera in every particular, except that instead of the more usual exudation from the bowels, this took place by the abundant out-pouring of the fluid of the blood from the skin, or sometimes into the cellular texture, either of whole or part of the body, producing either partial or general dropsy in the course of a few hours. This latter form was more especially frequent in infants and children. Sometimes, too, this serous exudation occured in a form not less rapidly fatal than the worst kind of cholera, by producing suffocation, in consequence of sudden œdema of the lungs. All these however, and various other anomalous affections, at length gave place to cholera in its ordinary form, with vomiting, purging, and spasms, as little marked by intermission as it ever is, and differing in no respect from that I had witnessed in Edinburgh and London. Its temporary disappearance was then followed by the return of remittent fever. In every one of these forms, however, the urine was invariably scanty, and of a dark porter colour, or wholly suppressed. In its second onset two years afterwards, cholera did not approach so gradually, but after having indicated its advent by a few cases of cerebral congestion and sudden death, it fell at once upon the population, with all the fatality with which its first arrival is everywhere characterized. Suffice it to say, that in all of these I found the same principle of treatment hold good, and even the same doses of a combination of iron with quinine, together with a careful use of bleeding in the commencement of the congestive stage, universally applicable; whether in the slighter cases of mere nervous affection, in the more decidedly periodical forms, or in those graver cases including true cholera, where the congestion was evidently too extreme to be within the power of medicine to overcome, without the mechanical aid afforded by the use of the lancet, and where the stage of intermission was only to be discovered by calculation of the time, and the most minute investigation.

I shall conclude this division of the subject by the bold assertion, as it may seem to many, even of those who have witnessed cases of the description I allude to, that within the last few weeks, commencing from the middle of September, several cases of quotidian congestion of the brain or other organs, so grave as to threaten life, and sudden unaccountable deaths from affection of the heart have occurred in Manchester, and I believe all over the country; and that these are attributable in my opinion, solely to the already prevailing tendency to venous congestion, and nervous disturbance proceeding from the cause, and perhaps preceding the actual appearance of the more obvious forms of cholera. The cases which I have myself met with lately of this character, have been total insensibility, resembling apoplexy, with extreme collapse, return of warmth, and again a stage of collapse on the following day; also hemiplegia without other symptoms of apoplexy, both yielding to quinine and iron; intermitting hemicrania, neuralgia, unusual pain and tension of the epigastrium, pains resembling rheumatism in every part of the body, aggravated by the usual treatment for rheumatism, but relieved by iron, and often accompanied with cold chill at a particular hour each day; also sudden attacks of vomiting and purging without tenesmus. These I shall probably have an opportunity of bringing to the notice of the profession in another place; my object here is not to detail cases, which others must have met with as well as myself, but by sketching the course of these diseases generally, to show how maladies, that, taken separately and without reference to the prevailing epidemic character appear to differ in every possible symptom, may yet be found when regarded *en masse*, to be very intimately connected.

I have been particularly desirous that your attention should be directed by the history I have just concluded, to the fact, that in every form of disease there mentioned periodicity has been a prominent characteristic, and that though obscure in remittent fever, in actual cholera and in some nervous affections, the close connection existing between them and decided quotidian ague in contemporaneous occurrence, sequence, and in their essential symptoms and means of cure, would scarcely admit of a doubt that periodicity exists in these also, even if it were more difficult to distinguish in practice than I have found it to be.

There is another point which can scarcely have escaped your observation in these forms of disease,—viz., the great variety of effects produced by the same exciting cause. Now, on the brain and nerves, with various, or without any, remarkable disturbance of the circulation;—now, on the bowels by constipation;—now, by diarrhœa;—now, by dry vomiting;—on the capillary circulation generally in ague, remittent fever, and cholera;—or locally, by arrest of certain secretions, or by exudations from the compressed and congested blood into a great variety of structures, &c., &c., for this alone I conceive would suffice to show, that such diversity of effect without a single constant concomitant, such as fever, could never be the result of altered blood without nervous impression, and functional disorder.

The invariable efficacy of iron in all these forms of disease, whether simply or in combination with quinine, will also, I think, sufficiently illustrate what it was formerly attempted to argue, that the different conditions of the nervous system and of the circulation, occurring in agues of different type, require a different action in the medicines by which the morbid influence is to be counteracted, according to the type or duration of intermission; for, in speaking of ague, it was remarked, that in quartan the febrile stage is greatest,—

that in tertian all three stages are well developed,—but that in quotidian the congestive stage is always the most severe, sometimes even to the exclusion of the others;—that, in proportion as the intermission is prolonged, the congestion is less severe, and the energy of arterial reaction more powerfully excited; but, as the cession of the vital powers to the morbid impression becomes more complete, the period of repose is curtailed, the febrile stage less perfect, and capillary action more impaired, especially in that part of it which belongs to the venous system. Thus quinine, which almost invariably cures tertian, is often found inferior in effect to arsenic in quartan, and in quotidian we have found it prove positively injurious till modified by admixture with iron, by which its ill effects were obviated, and its antiperiodic action restored,—a fact of no small interest in explaining the failure that has always attended the attempts to treat cholera with quinine and arsenic uncombined.

(*To be continued.*)

OBSERVATIONS ON CHOLERA.

By E. T. Roe, M.D., Plymouth.

The fertility of the human mind has never been more fully exemplified than during the last few months, in the host of remedies proposed for the cure of cholera, that dread malady which has been seen advancing upon us from barbaric realms in slow and measured step, unsated by the destruction of vast heathen hordes,—unchecked by human laws,—unknown as to its essential principle or mode of propagation; its onslaught sudden, fearful, deadly; its election of attack often governed by no circumstance of wealth or power, or health or situation; the young and old, the vigorous and feeble, alike drawn into its cold embrace. The malady indeed is of sufficient importance to demand from all of us the most serious prayerful consideration, and it is to be regretted that the mind should be distracted from its rational contemplation by crude and ill-digested, ill-judged, or reasonless surmises, and suggestions,—that it should allow itself to be led away by every new or startling theory, which "like the baseless fabric of a dream," vanishes when the mind resumes its throne. Every tyro knowing cholera only from books fancies himself propelled by an internal force to rush headlong into print, and give his lucubrations a local habitation and a name, and himself the practice he has vainly sought by other means, while maturer minds are racked with indecision, filled with fancies, and blown about by every wind of doctrine, hesitating and halting in opinion between carbon and creasote; naphtha and petroleum; calomel and opium; salt and mustard; and discarding all in their turn; and the astonished public looks on aghast, until, recovering from its surprise, it asks, "What are the doctors doing?" "How is it that they have found out no remedy for cholera yet?" Alas! God in His infinite wisdom has decreed that plagues and pestilences shall, at certain periods, devastate the earth, and that the hand of man shall be powerless against His will; but at the same time he gives us reason to view his judgments aright, and he mercifully permits us to use the agents he has given us, and which He, in His good time, will deign to bless. He has shown that He is not unmindful of those who are not unmindful of Him, and this favoured land can boast of sharing largely of His blessings. Had we done as we should have done in times of peace and plenty, and thought *then* of our poorer brethren, of their crowded rooms, their drainless courts and lanes, and the poisoned air they breathe, the measure of His grace would, perhaps, have been larger; but now, with the disease almost at our thresholds, we set about to put our towns in order for the poor's sake! Shallow hypocrisy: it is for our own, for we dread, and justly too, that if the poor have the disease, the rich will not escape.

With these preliminary remarks I will proceed now simply to the consideration of the best means of treating the *developed* disease, leaving to a future occasion any speculations as to the nature of that disease, as well as the questions of what should be done in the way of public hygiene, and what, in the various phases of general malaise, which are supposed by an alarmed and excited public to be the initial stages of the epidemic.

I will not insult my readers' understandings, nor occupy their time in combatting the various absurd theories indulged in, both in this country and elsewhere, nor chronicle the remedies based upon such fanciful and erroneous opinions, but pass on to notice briefly some of the most rational and well-devised plans which have been proposed, and which offer the greatest probabilities, humanly speaking, of being attended with success, and will then, as briefly, give the result of my own experience.

The scheme of supplying to the blood, by transfusion, the salts which had been drained from that vital fluid by the discharges, was, perhaps, one of the most taking promulgated during the last epidemic, but it has hitherto been found to be productive of only temporary rallying, not of permanent relief.

Carbon and carbonic acid, creasote, naphtha, and petroleum, may be classed together, and need not occupy us long. Each has its advocate, and there may arise cases in which each may effect a cure, but they do not come up to my idea of possessing sufficient energy to arrest the progress of so stern a malady as cholera.

Dr. Parkyn is an able supporter of the claims of carbonic acid in effervescence, and if it be found to check the vomiting, it will be valuable as an auxiliary remedy.

Brandy, cajeput, capsicum, and essential oils, have been found to relieve the distressing cramps, and rouse the vital energies for a time, but to how much of their influence may we ascribe the subsequent inflammatory re-action, often as fatal as cholera itself?

Other agents, as alkalies, salines, acetate of lead, mustard emetics, &c., are also recommended, but all sink into the shade, or become at best only of secondary importance when compared with calomel, opium,

antimony, and bleeding. The first has always had its advocates, and will be found most generally beneficial. Opium, although much abused by some, and, doubtless, a drug capable of producing dire effects when used without judgment, is, in judicious hands, extremely valuable. Antimony was proposed as a remedy in 1832, by Mr. Holt, of Manchester, and may be regarded as our sheet-anchor. Bleeding is a very good remedy in the early stages of the disease, but when collapse is well marked, or has existed long, no blood will flow, and even if it would, few, I think, would be bold enough to advise its abstraction.

A friend and patient of mine, a major in the East Indian army, who has spent the largest portion of his life in India, always had every person he could find attacked by cholera, and not under treatment, brought to his bungalow and bled, and he found that if blood could be obtained, those so treated recovered without any other means being used; but those from whom no blood would flow died, no matter what else was done.

It has recently been suggested that some of the diseased blood should be abstracted, and healthy blood transfused in its stead, but there are many grave objections to this course, and it is easy to demonstrate that it would be inutile in practice, for the same reason that saline transfusion fails; but I have already shown that in really severe cases of cholera, no blood can be obtained, so that the plan in its integrity is an impossibility.

The warm water and air baths, and the various ordinary means of external irritation, are useful assistants to every form of treatment, but the cold douche has often been more productive of reaction than warm applications.

I will now proceed to the plan I found most serviceable in my own practice.

In 1833 I had, by being connected with a large public institution, the opportunity of noting the effects of many and various remedies, and from none did I observe such marked and uniform benefit arise as from a combination of the potassio-tartrate of antimony, calomel, and opium. This formula, therefore, became the basis of my treatmnt, and from thenceforth no patient was lost if seen at all in time to give the slightest chance of recovery.

I found that a grain of the antimony, a grain of calomel, and half a grain of opium, in the form of a very small pill, or as a powder, mixed with honey or butter, every half-hour or hour, according to the severity of the symptoms, were the usual doses required, the only deviation being the occasional suspension or omission of the opium, if the diarrhœa ceased, or coma threatened. If the first dose was rejected, the second was given immediately; the vomiting was often aggravated for a short tme, but tolerance was soon established, the algide symptoms speedily gave way, and the apparently death-struck sufferer, in a few hours, was restored to health.

In all epidemics, and especially in cholera, the early sufferers are the first victims, and it was in 1832, as it will be, I fear, now, and as Mr. Thom, in his Admiralty Report, has stated it was recently in India, that the first cases were generally fearfully unmanageable, from causes easily explained, and that the means which failed in those frequently were most beneficial in the subsequent, and therefore less violent and acute forms of the disease. However, the cases I saw in 1833 were bad enough, and the dead were lying on every side, but after the adoption of the treatment I have detailed above, the deaths were very few and far between.

It may be remarked, that I have not alluded sufficiently to the remedies applicable to the stage of collapse only, but I have not done so from the painful conviction that when the algide symptoms are fully developed, the coagulation of blood that has taken place in the vital organs bars all hope of benefit from any human means.

Princess Square, Plymouth,
Nov. 18, 1848.

ON NITRE IN PURPURA HÆMORRHAGICA.

By Clement Carlyon, M.D., Truro, Physician to the Royal Cornwall Infirmary.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

In the number of the "*Provincial Medical and Surgical Journal* for Nov. 1st, my attention was drawn to an interesting case of "Purpura Hæmorrhagica," by Dr. Roe, of Plymouth. His patient survived with great difficulty, and is no doubt much indebted for her recovery to the skill and assiduity of her physician; but my long experience of the superior efficacy of other means than those employed by him, induces me again to communicate them to the public, through the medium of your widely circulated Journal; for, many years since, an article was inserted in the *London Medical Gazette* by me on this subject. My chief object on that occasion was to recommend the trial of nitre in cholera, under specified conditions, such recommendation being founded on my knowledge of its efficacy in purpura.

A work of high authority fifty years ago, and which I hope still retains the character of a very valuable book of reference, "Dr. Parr's Medical Dictionary," contains the highest imaginable encomium of nitre, as a medicine in cases of hæmorrhage. After alluding to other ordinary and often indispensable methods, such as general and local bleeding, &c., of lessening the current or moderating the impetus of the blood, "the first medicines," he observes, "to be employed in hæmorrhages are refrigerants; and the most effectual of these is cold water, internally; occasionally with frequently repeated, rather than large doses, of *nitre*. The latter is a remedy of the greatest importance, an *instar omnium*, in these complaints, especially when saline purgatives are interposed." "Nitre (he elsewhere adds,) is a very useful refrigerant. It restrains the too rapid current of the blood, reduces the pulse, and heat of the body, and is not only a very valuable medicine in inflammatory fevers, and in inflammations,

but also in hæmorrhages." In fact, he again and again refers to nitre as a most important medicine; and my confidence in his judgment and great experience, confirmed by the opinion of an eminent professor, whose lectures I had attended, led to the employment of nitre extensively in the early part of my practice. I was, however, after a while obliged to restrain its use very considerably. In active hæmorrhages, and in inflammatory diseases generally, it either wholly disappointed me, or was at best a very secondary minister of good. Still the high encomiums of Dr. Parr, and its good effects in particular cases, had their weight with me; and I persisted in endeavouring to discriminate between the proper use, and misapplication of, a medicine so highly eulogized.

At length I came to the conclusion, from an extensive comparison of cases, that its great virtue lay in its applicability to passive hæmorrhages, and to cases of purpura. By passive hæmorrhages, I wish it to be understood to mean cases where the inflammatory action has either been subdued by depletion, or has not appeared to precede the hæmorrhagic condition. It is not, however, in these cases that I consider nitre entitled to any exclusive preference, but only in such cases pre-eminently as partake of the character of purpura,—cases in which the blood is supposed to be in a dissolved and supercarbonated state; thin and ichorous, as in malignant fevers, in contagious dysentery, in cholera, in purpura, and in sea scurvy. For the general argument in support of this extensive view of its use, I must refer to a report, by Mr. Charles Cameron, to the Navy Board, relative to its astonishing efficacy in scurvy, and to my own letter in the *London Medical Gazette*, Vol. 8, my present object being chiefly to direct attention to such appalling cases as that of Dr. Roe. I am aware that the treatment adopted by him is still sanctioned by others of considerable eminence; but although his patient eventually recovered, it is evident that nothing short of his great attention, and the most skillful use of the means employed could have saved her. I could speak of similar cases in my own practice, where very much the same plan of treatment was unsuccessful,—cases which, if they came not fully up to the fearfully descriptive lines of Lucan, were equally characteristic of the disease in question.

"Sanguis erant lacrymæ: quæcunque foramina novit
Humor, ab his largus manat cruor: ora redundant
Et patulæ nares: sudor rubit: omnia plenis
Membra fluunt venis: totum est pro vulnere corpus."

I therefore determined to change my plan, and to substitute Dr. Parr's specific, for bark, mineral acids, and astringents generally. The result was beyond my most sanguine expectations. In purpura, and all analogous conditions of the system, nitre fully justified the appellative of "*instar omnium*." Discrimination, and the occasional interposition of purgatives, such, in particular, as combinations of rhubarb with carbonate of soda in full doses, will, nevertheless, be found indispensable; and when purpura hæmorrhagica supervenes, as it sometimes does, on a plethoric habit, even abstraction of blood, as a precursory measure, may be required. The diet should be the lightest possible; cold barley-water, or gruel, is the most appropriate. With respect to the best mode of exhibiting the nitre, I may repeat what I formerly said, —viz., that "it has agreed best when given with an equal quantity of sugar, in cold water, in doses of from ten grains to a scruple, every two or three hours, and, in urgent cases, still more frequently. In the mild ordinary cases of purpura simplex, the repetition of the dose three times a day will be sufficient." Mr. Cameron's dose in sea-scurvy was one drachm, with which he recommends vinegar and water as a drink, but this is a larger dose than the stomach will ordinarily bear; still it is impossible to lay down any rule for the extent to which nitre may be given in any particular case, and it may be said generally, that, as long as the stomach is not offended, there is no danger of excess. I have often, on the other hand, found five-grain doses enough. In the progress of convalescence, it will be well to make camphor mixture the vehicle of the nitre, and ultimately to substitute carbonate of soda for the nitrate of potass, in a ten-drachm draught of camphor mixture, to be taken twice or thrice daily for some time. This, with a gradually improved diet, will supply the place of all other tonics.

I am, Sir,
Your obedient servant,
CLEMENT CARLYON.

Truro, Nov. 24, 1848.

LETTER IN REPLY TO DR. COLLINS, ON THE DURATION OF LABOUR AS A CAUSE OF DANGER AND MORTALITY TO THE MOTHER AND INFANT.

By J. Y. Simpson, M.D.,
Professor of Midwifery in the University of Edinburgh.

To Dr. Collins, formerly Master of the Dublin Lying-in Hospital, &c., &c., &c.

My Dear Sir,—

Allow me to set you right in regard to some of the *new* statements which you have made in your second letter in the *Provincial Journal*. These new statements involve you only in new errors, and give me the additional trouble, and, let me add, the pain, of replying to them. You have, however, one great advantage. It is a hundred-fold more easy to make statements than to answer them. You, or any one, may at any time make in a couple of lines, an assertion which may require a couple of pages properly to analyse and expose. But let us proceed:—

1. You observe, "Professor Simpson asks why I did not state that during the first three years of my Mastership, out of 5629 women delivered, 106 died, or 1 in 53. In answer, (you add,) I could not state so and state a fact, as there were 7547 deliveries in the period stated, and 110 deaths, or 1 in 68."

The answer to this (the *only* point on which you challenge the correctness of my various computations,) is abundantly simple. If error there is, it is yours, not mine. It is in your statement of facts, not in my calculations upon them. Your Mastership of the Dublin

Hospital lasted for seven years, from November 1826 to November 1833. You declared in your first letter in the *Provincial Journal*, (p. 573,) that during the last four of these years 10,785 women were delivered. To use your own words, "for the last four years of my residence in the Hospital after puerperal fever disappeared, the very great number 10,785 of deliveries occurred." Further, in your second letter, you now declare that during the first three years of your residence, 7547 deliveries took place, and not, as I computed them, 5629. But if you had 10,785 deliveries during your four last years, as you stated in your first letter, and 7547 during your three first years, as you state in your second letter, then you must have had in all, not 16,414 cases, as you have always hitherto averred, but 18,332 cases; for 10,785 + 7547 = 18,332. Or, if you had in all, during your seven years' Mastership, (as you have always hitherto stated,) 16,414 cases only, and if 7547 of these occurred during the first three years of your residence, then only 8867 of them occurred during the last four years, and not, as you have before averred, 10,785; for 7547 + 8867 = 18,414.

My computation, that you had during the first period of your residence 5629 cases, with 106 maternal deaths, or 1 death in every 53, was built upon a very simple calculation, and one which is quite correct, you will find, according to the data which you yourself gave. You had, (according to your own first and reiterated statement,) 16,414 deliveries in all, with 164 maternal deaths; or 1 in every 100 mothers died. Of these 16,414 deliveries 10,785 occurred "during," or, as you express it, "for the four last years of my residence in the Hospital after puerperal fever disappeared," with 58 maternal deaths, or 1 in 186. Now, if you substract 10,785 from 16,414, you will find remaining for the first three years, the number I gave,—viz., 5629 deliveries; for 16,414—10,785 = 5629. Again, if from the whole number of maternal deaths—164, you substract the declared number during the four last years—58, you will find remaining as the number of deaths for the first three years, 106; for 164—58 = 106. And 106 deaths in 5629 deliveries, makes 1 death in 53, as I originally stated it. The whole may perhaps be more plainly expressed to you in three lines, as follows:—

During the whole—			
7 years, there were	16,414 cases;	164 deaths;	or 1 in 100.
For the last—			
4 years, there were	10,785 cases;	58 deaths;	or 1 in 186.
Hence, for the first—			
3 years, there were	5629 cases;	106 deaths;	or 1 in 53.

I repeat, then, that when I stated you had 5629 cases, with 106 deaths, or 1 death in every 53 deliveries, during the earlier part of your Mastership, and before puerperal fever accidentally disappeared from the Hospital, I stated precisely and accurately the results which your own data afford. My calculations are correct if your data are correct!

2. You observe:—"Professor Simpson states in reply to my remarks upon the excessive mortality of 1 in 21 in the Edinburgh Hospital (in 1821 and 1822) under the late Dr. Hamilton,—'you (Dr. Collins) know that this high mortality arose from the prevalence of puerperal fever.' I beg (you add) to say, that Dr. Hamilton peremptorily declares, that not one case of puerperal fever occurred in the above period. See the late *Dr. Mackintosh's Essay*, published in 1823, where *he asserts* the mortality was 1 in 18."

Upon this paragraph of yours, I must take the liberty of making two remarks. And, *first*, in the Essays of Dr. Mackintosh to which you refer me, that gentleman assuredly *nowhere* asserts that the mortality of the Edinburgh Lying-in-Hospital, in 1821 or 1822, or in any other year, was 1 in 18. Dr. Mackintosh knew far better than to make any such rash mis-statement of simple facts. It is *not*, as you aver, an assertion of Dr. Mackintosh's, but, I am sorry indeed to add, an assertion of Dr. Collins' own. You made it for the first and only time in which it was made, in a painfully violent and intemperate attack upon the late Dr. Hamilton, which you published in the *Dublin Journal* for 1838, and to which you refer in your first letter to me. And you must kindly excuse me, if I defend the respected memory of Dr. Mackintosh from the odium of calumniating his brother practitioners, by having made the improper and unworthy assertion which you choose to attribute to him.

The printed Annual Reports of the Edinburgh Lying-in Hospital, show, that, in 1821, 190 women were delivered within the Hospital. Of these 7 died, or 1 in 27. In 1822, 168 women were delivered within the Hospital, of these 5 died, or 1 in 33. During these two years, out of 358 women delivered within the Hospital 12 died, or 1 in 30.

But, *secondly*, these 12 women did die, as I have stated, of epidemic puerperal fever. It grieves me, and it must, I am sure, grieve your best friends and well-wishers, to see you anxious to deny this. As your authority, you yourself refer me to Dr. Mackintosh's Essay, (1823.) Well, in that work, Dr. Mackintosh gives the following summary of the symptoms in the seven women that died in the Hospital in 1821:—"They had," he says, "rigors; pain of abdomen and of forehead; progressive increase of pulse; difficulty of breathing; anxiously expressive countenances; tumefaction of abdomen. The lochiæ were not suppressed; on the contrary, they flowed in natural quantity and quality." (p. 31.) Ten pages further on (p. 41,) Dr. Mackintosh states that the five patients who died in the Hospital in 1822, "had analogous symptoms." Surely no obstetric pathologist or practitioner would or could say, that these cases, with these symptoms, were not cases of "puerperal fever," as you and I, and all of us understand that generic nosological term.* On this point I unhesitatingly appeal to Dr. Collins himself, but not to the writer (*scriptor præceps*) of the letters signed "Dr. Collins," in the *Provincial Journal*. Dr. Hamilton termed the cases "puerperal peritonitis." But *your* own author (Dr. Mackintosh, p. 12,) very properly designates any attempt in this way to deny that they were not instances of puerperal fever, as a mere "*sophistical* statement."

* A difference in the name makes no difference in the thing named. You call the disease "puerperal fever" in your Treatise. I sometimes give it the double name, "puerperal fever and inflammation," as marking the two principal morbid actions which exist and co-exist, not as cause and effect, but as co-incident effects, as I believe, of one common cause, viz., a diseased state of the blood. But still I repeat, a difference in the name does not alter the disease named.

Besides, that epidemic puerperal fever was very prevalent in Edinburgh in 1821 and 22, is well known to every obstetrician who is at all conversant with the literature of his profession. Two large octavo volumes were published on the special Edinburgh Epidemic of those years; one by Dr. Mackintosh, (to which you refer;*) the other by Dr. Campbell.† In his work on Puerperal Diseases, your own townsman, Dr. Churchill, bestows a page on the Edinburgh puerperal fever of these years 1821-22; and states (p. 289,) the disease "was epidemic in the Lying-in Hospital of Edinburgh in 1821-22."‡ It carried off, at that time, many patients in private practice. In his Essay, Dr. Mackintosh speaks of the late highly-esteemed Dr. Kellie, as one of the most experienced, and, in fact, greatest authorities "in midwifery." That excellent and able practitioner lost in Edinburgh and Leith, 15 patients from puerperal fever, during the prevalence of the epidemic I speak of.

3. In your article in the *Dublin Journal* to which I have above referred, you say the comparison of your practice with Dr. Hamilton's is like the comparison of "light with darkness," seeing that in the Edinburgh Hospital in 1821 and 1822, 1 in 21 died.§ I have above shown you, that the mortality was 1 in 30, and in my former letter to you, I stated that, *under the same circumstances*,—viz., the prevalence of epidemic puerperal fever, "in one year (1826,) when you acted in the Dublin Hospital, partly as Assistant Physician, and partly as Master, 81 out of 2440 women delivered, died, or 1 mother in every 31." In your last letter you do not gainsay the fact of this high mortality in that year; and you further confess, that you acted as Master from November 1826; but you aver that it is "contrary to the fact," that you were Assistant-Physician in the earlier part of that year. It is a matter, as you must be aware, of little, or indeed of no moment, so far as regards the main question, viz., the mortality in the hospital under puerperal fever at that time. But I made the statement in consequence of your having published in 1836 the following remark in the preface to your Treatise:—"These opinions [the strikingly small mortality from protracted labour, &c.,] I can (you say,) with truth state, have not been rashly formed; on the contrary, they are the result of an anxious and diligent attention to the duties of my office, as Assistant and Master in an Hospital where I resided *for a period of ten years, commencing February* 1822, during which time, 24,119 deliveries occurred.—(*Preface*, p. 11.)

4. You observe,—"Professor Simpson states that he thinks he sent me a report of the Edinburgh Hospital, which I never even heard of."

At your own private request, I sent you a duplicate of this report a short time ago. And lest you should still miss the part alluded to, let me quote it for you. It is at the bottom of p. 2, and runs thus:—"A report has been circulated against the Hospital to the effect that the mortality amongst its patients has been of late unusually great. The very reverse of all this is the truth. From the 21st June, 1839, to the 15th October, 1840, 212 were delivered within the Hospital, and all of them recovered. During the same time, 718 cases of labour occurred among the out-patients; of these only one died, and that in consequence of organic disease of the heart. It is confidently presumed, that no Lying-in Hospital in the United Kingdom can show so small a mortality within the same period. In the great Westminster and Dublin Hospitals, from 1 in 80 to 1 in 150 of the women delivered, have, for some years past, died during their confinement. Among the patients of the Edinburgh Hospital, only one in 900 died within the period alluded to."

I do not state this result of 1 death in 900, when puerperal fever was absent, with any view whatever of boasting of superior success over others, such as you have so repeatedly and strongly claimed for yourself, when, under the same circumstances, (viz. the absence of puerperal fever,) you lost 1 in 186. But I recall your attention to the result, for another reason, viz., in consequence of the averment or assertion that you thought fit to make in your first letter, that 1 death in 21 "is the *only* record in existence (I quote your own words.) of the mortality of this public charity," the Edinburgh Lying-in Hospital. I am perfectly aware that a practice under selected time and selected circumstances, such as your return of 1 in 186 in Dublin and the above of 1 in 900 in Edinburgh, does not represent the general average mortality at other times, and under other circumstances. During your first three years Mastership, when puerperal fever was occurring in the Dublin Hospital, you lost 1 in 53; and during the first two years of the Edinburgh Maternity Hospital,* viz. from 1844 to 1846, when puerperal fever was more or less prevalent in the house, there was exactly the same mortality of 1 in 53; 7 women dying among 574 in-patients. Among the out-patients of the same Institution, (the Maternity Hospital,) during the same period, only 4 died out of 1101 deliveries, or 1 in 275. The mortality among the in-patients was somewhat above the proper standard, and the most mortality among the out-patients was somewhat below its standard, in consequence of out-patients, when severely ill, being sometimes transferred to the Hospital, and in one or two instances dying there. But I believe you will find, that the markedly greater mortality here as elsewhere, in hospital, than in dispensary or private practice, arises principally, or indeed almost

* A Treatise on Puerperal Fever, &c. (1822,) and Reply to a Pamphlet on it, (1823.) It is this last work, (1823,) to which Dr. Collins refers, and from which the above extracts are taken.

† A Treatise on the Puerperal Fever, as it prevailed in Edinburgh in 1821-22. "It visited," says Dr. Campbell, "this establishment (the Lying-in-Hospital,) in 1821-22, and proved fatal to several patients," p. 16.

‡ Observations on the Diseases of Pregnancy and Childhood, (Dublin, 1840,) p. 285, 286.

§ "The *difference* in practice [between me (Dr. Collins) and Dr. Hamilton.] is truly remarkable, and the familiar comparison of *light* with *darkness* is very *appropriate*."—*Dublin Journal* for 1838, p. 320. In this extract, I beg to state that I have left the italics exactly as Dr. Collins himself originally printed them.

* To prevent mistakes I ought perhaps to state that two Edinburgh Lying-in Hospitals are alluded to in the text,—1. The old "Lying-in Hospital," Park Place, opened in 1793, and broken up in 1843, in consequence of debt and defect of funds; and, 2. The "Maternity Hospital," opened in 1844, in St. John Street, and now removed to Milton House, Canongate.—See a report of the first two years practice in the Maternity Hospital, in the November number of the *Monthly Journal of Medical Science*.

entirely, from the greater liability of hospital patients to puerperal fever; and when this accidental "complication," (as you term it) chances to be absent for a time from an hospital, the rate of mortality may be decreased unusually for that time, as during the fortunate "accidental" absence of it in the last four years of your mastership, and in the Edinburgh Hospital for 1839, 1840. If the master or captain of a sailing vessel happened to make an unusually fortunate run from Liverpool to America, or to the West Indies, in consequence of the "accidental" circumstance of having a fair wind during the latter half of the voyage, surely that is no reason for him to arrogate to himself a knowledge of seamanship superior to all other captains and masters, who did not happen to meet with the same "accidental" fair wind. If such a person should in consequence talk modestly of his nautical skill, as compared with that of compeers, as "light with darkness," pray, in your opinion, what should his compeers really think of him? I should be afraid to tell you openly my honest opinion upon the matter.

In your first letter in the *Provincial Journal*, you declare the mortality in the old Edinburgh Lying-in Hospital to have been "unprecedented." At the time of your controversy with Dr. Hamilton, Dr. Moir, who acted for many years as physician in that Hospital, summed up with great care and labour the results of 2890 cases of delivery within the Hospital, which had occurred in the course of the fourteen previous years, and with the intention of publishing them. But other duties interfered at the time with that intention, and he lost interest in the question, and the papers have since lain beside him in an unfinished state. He empowers me however, to state, that among these 2890 cases, only 11 deaths, or about 1 in 260 occurred from other causes than puerperal fever. There was scarcely, if ever, a single year of perfect freedom from attacks of puerperal fever, and 36 out of the 2890 patients died from its effects, or about 1 in 83. Altogether, including the accidental deaths from puerperal fever, 47 women died out of the 2890; or about 1 in 61. During the same term of years 5916 of the patients of the Institution were delivered out of the Hospital; of these 5916 out-patients 24 died, or 1 in every 246; and of these 24 deaths 14 were from puerperal fever. These cases, as I have said, occurred during the fourteen years, from 1823 to 1837. In your Hospital in Dublin, during the same fourteen years, viz., from 1823 to 1837, (and with all your superior advantages in accommodation, in attendants, in space, in bedding, and in riches) out of 34,170 delivered 472 died, or 1 in 72, and an enormous number of the children were lost. These years include too, your four "accidental" years in which there was puerperal fever. If we exclude these four years, viz., from 1830 to 1833, then the mortality in the Dublin Hospital from 1823 to 1837 was 1 in every 5. In the Edinburgh Hospital, at the same time, among the in-patients 1 in 61 died. Among both the in and out-patients taken together, the maternal deaths amounted to 1 in every 124. Methinks, then, if the mortality in the old Edinburgh Lying-in Hospital was (as you assert,) "unprecedented," it has, at least been very fully "equalled" elsewhere.

But, let us proceed one step further, and enquire which of the two Hospitals, (the Dublin or the Edinburgh,) presented the greatest obstetric mortality during these years.

Now, you have repeatedly, and at various times and places, declared that puerperal fever may be considered an "accidental" complication* in hospital practice; and hence, I take it, you believe that the deaths from this cause being independent of the previous obstetric treatment of the patients, may be omitted (as you have proposed to do,) in any computation where we attempt to trace a statistical difference in the effects of different modes and forms of actual obstetric practice. In the Edinburgh Hospital during the fourteen years above mentioned, out of 2890 deliveries, 36 women died of puerperal fever, or 1 in 83; and 11 died from other causes, or 1 in 263. The published returns of the Dublin Hospital do not show how many died during these fourteen years, of puerperal fever, and how many of other more truly obstetric causes. But your returns for seven of these years shew this:—During these seven years, out of 16,414 mothers 56 died from puerperal fever, or 1 in 293; and from other causes 108, or 1 in 152. Putting then aside in both Institutions, the deaths arising from that "accidental" cause, (puerperal fever,) the resulting practice is as follows:—In the Edinburgh Hospital 1 in every 263 mothers died; in the Dublin Hospital 1 in every 150 mothers died. Perhaps the result will be more clear if I place it in a tabular form, as follows:—

Hospital.	Total Cases.	Deaths from other Obstetric and Pathological Complications.	Deaths from Puerperal Fever, an "Accidental" Cause.
Dublin ..	16,414	108, or 1 in 152	56, or 1 in 293
Edinburgh	2890	11, or 1 in 263	36, or 1 in 83

This table and the preceding statements will, I think, satisfy you that the obstetric practice of the Edinburgh Hospital was really not so "unprecedented" in its effects as you have at several times anxiously attempted to declare it. And I have sincere satisfaction in publishing these results, for this reason, that they will show to all unprejudiced minds, on what unfortunate and very erroneous grounds you proceeded in that attack of yours upon the late distinguished Dr. Hamilton, to which you and I have already referred in the course of these letters.

In your "Treatise" you state that out of 17,308 women delivered in the Lying-in Hospital of Paris, nearly 1 in 24 died. In that Hospital, in 1829, puerperal fever raged in every form, (see the descriptions of Tomelle, Dance, Duplay and others.) Without, of course, telling the cause of the mortality, you further state in your Treatise, (p. 343,) that in the Parisian Hospital in that year "1 in every 12 or 13 women delivered died." In the *Dublin Journal* for 1838 you further aver (p. 420,) that in the Edinburgh Hospital in 1821—22, (when, as we have seen, puerperal fever also prevailed,) the mortality was "1 in 21." I have already shown you it was 1 in 30. I leave,

* See, for example, your "Treatise," p 365; your papers in the *Dublin Journal*, Vol. xi., p. 42, and Vol. xiii., p. 406; and your first letter in the *Provincial Journal*, p. 573.

however, your two premises or assertions about the amount of mortality in the Parisian and in the Edinburgh Hospitals for what they may be worth; but the arithmetical inference which you draw from your premises, that "the mortality in the Edinburgh Hospital was more frightful than in the Paris Hospital," is surely rather too strong an experiment upon the credulity even of your Irish readers. I strongly suspect that the inference at least is, as you call it "unprecedented" in medical logic and medical arithmetic.

5. In a postscript to your first letter to me you denounce, or rather attempt to denounce, the mortality of the Edinburgh Maternity Hospital since the introduction of chloroform, as "frightful." And you come to this conclusion by perverting (no doubt unintentionally,) the returns which I gave of it, in a Report on Anæsthesia, published in the October number of the *Monthly Medical Journal*. The facts stated in that Report in reference to the use of chloroform in the Maternity Hospital were these:—To test its usefulness, effects, mode of action, &c., in natural labour, it was stated that up to the date of the Report it had been employed in 88 natural cases. Of these 88 mothers one died six days after delivery, from convulsions connected with albuminuria and diseased kidneys. The other 87 women recovered, their recoveries being "altogether more perfect and speedy" than usual. There were other 50 or 60 cases of natural labour in which chloroform was not used, from the labour being very speedy, &c., and all these mothers recovered. Chloroform was also used in seven morbid labours that happened to be brought into the house, viz., three cases requiring forceps, and four cases requiring turning. These patients were put under chloroform at the time of operating, to save them from the pains and shock of the operation. Two died,—one of the turning cases from rupture of the uterus; and one of the forceps cases from sloughing of the maternal passages. This last patient had been allowed to be greatly too long in labour before she was operated upon and chloroformed; and let me remark, it was the only instance I ever saw in Edinburgh of sloughing of the maternal passages, but it is an affection which is, I believe, by no means very rare in your Hospital.

Now, what do you with these data? You take the cases in which chloroform was used in natural labour; to these you add the seven cases of difficult operative delivery in which it was employed, and where the danger or death of the patient was surely not from the chloroform, (for I scarcely fancy you will go the length of alleging chloroform can produce "rupture of the uterus or sloughing of the passages.") You thus ungenerously get 95 cases in all, with 3 deaths, and then declare 1 maternal death in 31, as "the result of anæsthesia." I will not venture to comment upon such a mode of professional argument. To carry out and perfect the same unique process of reasoning, you should have taken the 7 instrumental cases alone, and then declared 1 death in $3\frac{1}{2}$, as "the result of anæsthesia." It would have been equally fair. In the Report from which you have culled the preceding data, I have reported from various quarters 8 or 900 cases of delivery under chloroform, and in some of them (as in the above,) the chloroform was used merely because the cases were bad or instrumental; and yet of the whole, 7 died—4 of the 7 from epidemic puerperal fever. I do not know if it will interest you, but I may add, that within the last week I have received from America the first volume of the "Transactions of the American Medical Association." In it there is a Report by a Committee of the Association in May last, on Anæsthetics in Midwifery. From this Report I quote for your information a single sentence, to show you that there is not as much staunch professional prejudice in America as in Ireland. "The anæsthetic agents, æther and chloroform, have now been used in perhaps 2000 cases of midwifery; and, so far as the Committee have been able to learn, without a single fatal, and very few, if any, untoward results." (p. 228.)

6. In both your letters you decry, or attempt to decry, the results of my private midwifery practice. When you did so in your first letter, I abstained from answering it, for I thought you had committed yourself in an unguarded and hasty moment, and would betimes see that it was wrong in a physician, and above all in you, the President of the College of Physicians of Ireland, to indulge yourself publicly in any attack upon the private practice of any member of the profession. As, however, you seem to have no such feelings, and repeat the attack in your second letter, let me at once answer it. In the report on Anæsthesia above alluded to, I state that I had used anæsthetics in 150 cases of midwifery in private practice; that out of these 150 cases one child was still-born and putrid; the other 149 were born alive; and that of the mothers, 2 died from epidemic puerperal fever, (which was prevalent here at the time;) all the others recovered. In the Report I farther mentioned, that since anæsthesia was introduced into midwifery, I had attended 20 or 30 other cases where anæsthetics were not used, and two mothers out of this class died,* —one under an attack of puerperal convulsions and coma that suddenly came on fourteen days after delivery, (she had been greatly agitated by her husband having been found dead in bed two or three mornings before;) and the other about three weeks after delivery, from an attack of fatal syncope apparently connected with acute endocarditis. Both patients were well till a fortnight after delivery, and consequently would have been most certainly reported as recoveries instead of deaths in the Dublin Hospital, where the patients, if able, leave on the eighth or tenth day,—a means by which, you will allow me to remark, the *apparent* mortality with you is no doubt considerably diminished.†

* If anæsthesm had happened to be used in these two cases, would you not, for one, have roundly declared the two deaths to have been the indubitable results of the anæsthesia?

† You must permit me to direct your attention strongly to this matter,—the *early dismissal* of your patients, as a most important point of fallacy between your returns and those of some other hospitals. In addition to the two above cases of deaths from causes supervening suddenly on or after the fourteenth day after delivery, let me state that, out of the nine deaths alluded to in the text as having occurred in the course of my private practice, a third,—viz., the one from acute mania, came on also upwards of a fortnight after delivery. My patient was already in the drawing-room, when some very afflicting family news was incautiously communicated to her. She was led back to her bed-room maniacal, and died in a few days. Hence, I repeat, out of these nine fatal cases, three of the deaths originated from causes and attacks coming on a fortnight after delivery; and of the

The first of these patients was so well as to be again under the charge of her ordinary medical attendant, Dr. Maclagan; the second had been delivered so easily and speedily, that there was no sufficient time even to send a messenger for me before the child was born, and her convalescence was so perfect for the first fortnight, that I did not see her above four or five times during all that period. But to quote your own words, "*I* (Dr. Collins) *can aver, we know of no such mortality in Ireland.*" Of course. But then we have already seen that your memory and judgment sometimes betray you about averments and assertions. Let me merely add, that in upwards of 1000 cases of labour which I have now had in private practice, I have lost five other cases within the puerperal month; three from puerperal fever—one from acute puerperal mania—and one from slow draining hæmorrhage after delivery, (there were found on dissection by Dr. Malcolm and myself, upwards of forty fibrous tumours in the uterus.)

And I think I am quite entitled to add, that I have had entrusted to me, for some years past, from various parts of the United Kingdom, a number of difficult and complicated obstetric cases, amounting to far, very far, above the share of morbid labours that are usually met with in any common single practice. At the present time for instance, I have under my care, among other such cases, two of advanced pregnancy, complicated with one or two lesions, that proved fatal in a case mentioned above, namely, the presence of large fibrous tumours in the uterine walls; and one of these patients has come several hundred miles to be under my professional charge, in consequence of the danger apprehended from this disease at her approaching confinement.*

The Provincial Medical Association of England (in whose Journal this letter and yours are printed,) is a Society of high minded professional gentlemen; and as I finish this paragraph, I feel that I owe them an apology for obtruding upon their pages such a subject as the defence of my private practice; but I trust they will kindly excuse me, when they remember that it was you, in the first instance, who did not scruple to force the matter, however improperly, upon their notice, and upon mine.

A distinguished countryman of yours, an enthusiastic Irish writer and politician, Thomas Davis, a few years ago, gravely proposed, as the surest method of regenerating Ireland, that you and his other countrymen should reject the English language, and talk in nothing but the old Irish or Celtic tongue. "Nothing," says Mr. Davis, (I quote from his Literary and Historical Essays, p. 177,) "nothing can make us believe that it is natural or honourable for the Irish to speak the speech of the alien, the invader, the Sassenagh tyrant, and to abandon the language of *our* kings and heroes. What! give up the tongue of Ollamh Toohla, &c. &c." On reading over your first strange and characteristic letter to me in the *Provincial Journal*, your amusing anxiety to resist my calculations, and defy my inferences, seemed to me rather analogous to the reasoning of Mr. Davis. "Nothing can make us believe that it is natural or honourable for the Irish to adopt the doctrines and computations of the alien, &c. &c." But in this thought, I fear I did your countrymen, and you, injustice. From several of them (and some of them your personal friends,) I have had letters confessing the soundness and importance of the generalizations which I have drawn from your data, and regretting the absurd and untenable ground you had taken up. Since you yourself only challenge *one* of my calculations as wrong, (and yet the error there, if any, as I have already shown, is yours,) I must believe that you could find no flaw in the various other and far more important computations which my first letter to you contained, otherwise you would have pointed it out.

Amid the various irrelevant subjects into which you branched off in your first and second letters, let us not forget that the *main and original question* to which these unchalleuged figures refer, was the question of the effect of protraction increasing the mortality accompanying parturition to both mother and child. Dr. Hamilton declared it as the result of his observations, that besides this, the protraction of labour produces in the mother also an increasing liability to retention of the placenta, to uterine inertia, and hæmorrhage, to febrile and inflammatory affections, &c. All this you asserted was not the fact; but all this and more your own data show, by the clearest and simplest *statistical evidence* to be the fact. I have already, in my first letter, given you a specimen in regard to puerperal fever. Nay, if you had actually invented cases and figures to disprove your own doctrines on these points, you could not have well suggested more strong figures for the purpose than are to be found in your Practical Treatise. When our busy season here is over, I shall send you a copy of tables

nine, only six would have appeared as deaths in such returns as yours. For, in your "Treatise" you state (p. 500,) that in most instances the mothers were dismissed "eight, nine, or ten days after delivery." I do not mean to argue that you would have returned a third more of deaths, if, instead of dismissing your patients on the eighth or tenth day, you had kept them, as in some other hospitals, for fourteen days, or longer. But I feel quite certain of this, that by thus getting your patients' names so early removed from the books, you more or less greatly diminish the apparent amount of mortality.

* Permit me to make in this foot note a remark which the re-reading of the text strikes me as being an omission. I have alluded to the frequency with which difficult cases of midwifery happen to be entrusted to my care. I have instanced one complication, (the co-existence of pregnancy with very large fibrous tumours,) because the two cases alluded to happened to recur to my mind at the moment of writing. Take them then as an example. Such cases are sufficiently rare, (I do not remember that you mention one among your 16,414 hospital patients,) and I think you will not deny that they are also sufficiently dangerous. I have just turned up the work on Pregnancy by your townsman, Dr. Montgomery. At p. 183, he says, "When such tumours acquire great bulk, and pregnancy occurs, they give rise to a combination which is fraught with fearful dangers to the unhappy sufferer." Further, be so good as remark, that I do not object to your counting the results of my private practice, provided *only* you count them honestly and fairly, and provided also you recollect the great over-proportion of difficult and consequently dangerous cases which my position here (however unworthily,) brings under my care. To go back to the same obstetric complication as an illustration, (for one illustration is as good as another,) let me add, that in the course of the last four or five years, I have had placed under my charge, during labour, (and *merely* because they were considered bad and dangerous cases,) five cases of pregnancy and delivery, in addition to the two mentioned above, complicated with these large uterine tumours; one of the five being the fatal case alluded to in the text.

on these points, that I calculated from your work, and laid before the Medico-Chirurgical Society here two or three years ago, and which I certainly would have published ere now, had I not kept them back purely in deference to your feelings, on a subject on which you had already so strongly and unfortunately committed yourself.

Before closing, permit me one word more. I beg you again to remember, that the present discussion was, in the first instance, entirely commenced on your part, not on mine. I have hitherto stood mainly on the defensive. If, in doing so, I have hurriedly or incautiously used at any time any expression that is in any way improper, I beg to express my sincere regret for it. And if I have made unwittingly any statement that is erroneous, I shall be happy to correct it. But remember, I do not promise to answer any further communications on the present points. If you will go wrong, I am not surely to be continually taxed to keep you right. For, my dear Sir, I have at this season, really much more important duties to attend to than to prevent the President of the Irish College of Physicians from committing open irregularities in statistical and other professional matters. If, however, you choose still to persist in this course, I must transfer the answering and further charge of you to some of my young and idler medical friends.

Very faithfully Yours,

J. Y. SIMPSON.

Edinburgh, Nov. 18, 1848.

[We have to apologize to Professor Simpson for allowing the passages calling in question his *private* practice to appear. We ought certainly to have exercised the editorial privilege of erasing the passages referred to from Dr. Collins' letters.]

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF PROFESSOR SANDS COX, F.R.S., SENIOR SURGEON TO THE HOSPITAL.

Reported by PETER HINCKES BIRD, Resident Medical Officer.

CASE XIII.

CANCER OF THE TONGUE.

Augustus Faulkner, aged 45, glass-drop grinder, was a patient in the Queen's Hospital under Professor Cox, in March last, with cancer (scirrhus) of the tongue; it was entirely extirpated by excision, the wound healed up, and he was discharged relieved in April, at which time there was no sign of any re-appearance of the disease, either in the tongue or in the glands of the neck.

He states that about three months after the extirpation of the tongue, he first perceived a re-appearance of the disease on the back and left side of the remains of this organ; it gradually got worse, and was attended by pain, described as sharp, shooting; about the same time he perceived that the glands under the left jaw began to swell, and they have gradually increased in size ever since. Various applications have been employed, but without any permanent relief. Opiates have been given to allay the pain.

October 8th. He now attends as out-patient at the Hospital, and is in the following state :—Countenance sallow, anxious, and dejected; the glands of the neck on the left side have swelled to about the size of his fist; the tumour feels soft and fluctuating, and gives him great pain, described as being constant, lancinating, shooting to the ear and top of the head; the tumour appears also to extend into the throat, and is seen to occupy the left side behind the soft palate. On examination the remains of the tongue appear indurated, and the back of the tongue on the left side is covered with fungous granulations, and discharges a thin, and sometimes a very offensive matter; the tumour in the throat interferes very much with deglutition, but his appetite is good; the pain prevents him from sleeping; he cannot open his mouth so wide as he used to do; pulse very feeble, 74; bowels open; no cough; no pain in the chest. R. Acid. Nitr. Dil., dr. iij.; Inf. Rosæ Co., Oss. M. Fiat gargarisma. R. Pulv. Opii, gr. iss.; Conf. Rosæ, q.s. ut fiat pil., omni nocte sumenda.

14th. Admitted as in-patient. Complains of the intense pain; the tongue discharges from the posterior part matter of a very fœtid odour; he cannot masticate solid food. Continue the medicine. To have broth, beef-tea, light pudding, ale, &c.

19th. The glands on the right side have begun to swell, and feel painful; the swelling on the left side is getting very soft towards its lower part; he also complains of pain in the right ear; the ulcer at the back of the tongue discharges as much (he says,) as half-a-pint of offensive matter in the course of the day; the pain in the left side of the neck still continues as before; sleeps indifferently at night; cannot open his mouth wider than to admit his finger. R. Liq. Opii Sed., m. lx.; Tinct. Camph. Co., dr. ij.; Aquæ, oz. j. M. Fiat haustus hora somni sumend.

28th. The tumour on the side of the neck is very soft and fluctuating. Mr. Cox introduced an exploring needle, and a few drops of fluid followed; a small trocar and canula were then introduced, and about three ounces of a fluid, of a light yellowish brown colour, were drawn off; this fluid contained numerous flakes, which, under the microscope presented numerous nucleated cells and plates of cholesterine; cholesterine was also obtained by evaporating the fluid to dryness, and adding æther to it.

November 5th. Feels worse, the pain is much complained of; the swelling in the parotid region is again increasing; the ulcer at the back of the tongue discharges a great deal of thick matter, tinged with blood; he complains of slight cough at times, with expectoration; there is slight pain in the right hypochondriac region; throat feels very sore; complains of sharp pain in both ears; is evidently getting weaker. The draught at night only eases the pain for a time. R. Pulv. Opii, gr. iss. Conf., q.s. ut fiat pil., ter die sumend.

9th. The swellling in the left parotid region is again increased in size, and distinctly fluctuates; four ounces of fluid similar in appearance to the last were drawn off.

He has latterly been troubled with cough, and to-day it is very troublesome; the glands of both sides of the neck, more especially on the left side, are enlarged and indurated. He complains of much pain round the head, and in the ears; the tumour at the back of the tongue is getting larger, so that both respiration and deglutition are considerably impeded. The ulcer at the back of the tongue discharges a great quantity of thick offensive matter, streaked with blood.

12th. Last night he was suddenly taken worse, with symptoms of suffocation, but which soon went off; he, however, gradually got worse, falling into a state of coma, and died about twelve, p.m., asphyxiated.

Post-mortem. Body well developed, and covered with a thick layer of adipose tissue. On opening the thorax, the first thing that struck my notice was that the lungs entirely occupied the cavity of the pleuræ. There was a layer of fat in the anterior mediastinum. The pericardium was distended with air, and in addition contained one drachm of straw-coloured serum. There was a considerable deposit of fat over the right ventricle; beneath the visceral layer of the pericardium there were two white patches of lymph, indicating old sub-acute pericarditis; the veins of the heart were congested; the right side of the heart was also gorged with black blood; the walls of the right ventricle were apparently thicker than natural, and contained one or two small deposits of fat, interspersed between the muscular fibres. The tricuspid valves and orifices healthy; the pulmonary orifices and valves healthy. Left ventricle decidedly hypertrophied; columnæ carneæ and chordæ tendineæ well developed; the mitral orifice healthy; mitral valves healthy. The coats of the aorta, as far as the bifurcation of the iliacs, healthy. Lungs of a deep red colour, owing to venous engorgement; the apices of both lungs were adherent at their posterior part; the right lung contained a cretaceous deposit; the mucous membrane of the trachea and bronchial tubes was in a state of congestion, and the bronchial tubes contained a small quantity of frothy mucus. Weight of heart and lungs four pounds three ounces. The mucous membrane of the stomach was congested, and thrown into large rugæ, particularly in the course of the great curvature; the muscular structure near the pyloric orifice was much thickened. Intestines not examined. The liver weighed three pounds six ounces, was very friable, but otherwise appeared healthy. Kidneys were extremely gorged with blood, but in other respects apparently healthy. Ureters healthy.

On the posterior part of the remains of the tongue was a large fungoid mass, of very irregular shape, containing in its cavities a very offensive pus; the epiglottis was evidently much pressed down by the tumour, and was only slightly open; the thyro-epiglottidean folds of mucous membrane were much thickened. A thin slice, taken from the diseased mass, submitted to the microscope, presented numerous nucleated cells, some of them of large size. The tumour on the left side of the neck contained about one ounce and a half of the same fluid as previously described; the walls of the cyst were composed of integument externally, and of the sterno-mastoid muscle and other tissues internally. The sub-maxillary gland was converted into a mass of scirrhous matter, cutting firmly under the knife, and exhibiting the fibrous bands; the sublingual glands were also the seat of the morbid deposit. The inner side of the cyst was also lined with scirrhous matter; the nerves on this side of the cyst were plainly seen without dissection. Several of the glandulæ concatenatæ were filled with a chalky deposit.

The history of this case previous to the operation of extirpation, and the details of the operation, together with the causes, and a statistical account of this disease, have been published,* but the unfavourable result of the operation remains to be told. The prognostication there delivered has been verified: in less than three months after the excision of the tumour, the disease returned, and by its gradual increase, caused death by asphyxia.

Dr. Warren relates a case in which the affection reappeared within two months after the operation, and, as a proof of its occasionally rapid growth, records a case in which a small hard lump on the edge of the tongue was changed into an extensive ulcerated fungus in eleven weeks, rising half an inch above its surface, and covering half its breadth. In a case mentioned by Mr. Cæsar Hawkins, it re-appeared in five weeks. I am not aware that there is any authenticated case on record in which the operation of extirpation was not followed by a reappearance of the disease.

From the appearance of the lungs of the above individual, it would seem that some time since he had tubercles deposited in them, but that on the supervention of the cancerous disease, the tubercular disease was put a stop to, and the tubercles became converted into a cretaceous substance.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, DECEMBER 13, 1848.

The crowded state of our columns again prevents our taking up the question of the constitution of the Sanitary Board, and of the Board of Health, with any prospect of doing the subject justice. On the general constitution of the former of these Boards we have little to remark. Dr. Southwood Smith, and Mr. Chadwick, are both well versed in the details of one portion of the duty which the office requires, and the energy and perseverance with which the Earl of Carlisle, then Lord Morpeth, carried the Public Health Bill through the House of Commons, together with the knowledge which he must necessarily have gained in the course of his inquiries into sanitary questions in general, cannot but have rendered him well qualified to superintend the working of his measure. The chief fault which we find with the constitution of this Board is its one-sidedness.

* *Prov. Med. and Surg. Journ.*, No. 47, Vol. iii.

Several of its members are sufficiently alive to the evils attendant upon foul sewers and drains, but there are other very serious matters connected with public health which are, we fear, likely to escape attention. It would have greatly contributed to the efficiency of this Board, and to the well-working of the Act, if two or three more well-selected medical members had been added to the Commission; and not to particularize further, we cannot but think that the unwearied exertions of Mr. G. A. Walker, in one important section of the duties which ought to come prominently under the consideration of any Sanitary Board, and his great practical knowledge of the entire subject of intra-mural interment, would have rendered his presence there an acquisition.

The great fault, however, in the working of the Sanitary Act, is in the local appointments. It is quite true that for the mere purposes of inspecting foul drains, and directing the cleansing of cesspools, &c., it matters little whether such duty is intrusted to a scavenger, a surveyor, a barrister, or any other functionary, public or private, whose tastes or interest may lead him to seek the office. Looking to it indeed in this point of view only, we should be glad to see the members of the medical profession relieved from the nauseous, and not very elevated, occupation, of following the scent of every disgusting nuisance which the carelessness, and inattention, and filthy habits of dirty people may engender. But there are very many other questions connected with the public health to which the attention of a Health-Officer should be constantly alive, and which can be comprehended only by educated medical men. Thus without due precautions, many of which would scarcely be suggested to, or understood by, any but a professional man accustomed to look into the causes of disease, and trace them to their sources, the opening and cleansing of a foul drain, or loaded cess-pool, might be, and indeed has been, the cause of extending and disseminating the very evil which it was intended to remedy or avoid. The all-important advantages resulting from the due supply of pure fresh air and *light* to the dwellings of the poor especially, can only be properly appreciated by the medical man. Many other questions are likely to arise requiring a considerable degree of medical knowledge in the Health-Officers, such as the means to be taken necessary to prevent the outbreak, or limit the spread, of any prevailing epidemic; but there can be no occasion further to enter upon them now, as the very term is a misnomer, if applied to any other than a person every way competent, by previous acquaintance with the structure and formation of the living body, both in the state of health, or as variously modified by the changes induced by morbific agents. We must reserve the expression of our opinion on the constitution of the Board of Health for another occasion.

Reviews.

The Transactions of the American Medical Association. Instituted 1847. Vol. I. Philadelphia: 1848. 8vo., pp. 403.

We have great pleasure in submitting a notice of this work to the members of the Provincial Association. The American Medical Association is a newly established Institution, founded partly for the same purposes as the Provincial Association, and may be said to represent the entire medical profession of the United States.

The volume before us is among the first fruits of this Association. It consists of the minutes of the proceedings of their first annual meeting, and of a series of reports drawn up by committees appointed for the purpose on the various branches of medicine. These documents are:—1. A Report on Medical Sciences. 2. On Practical Medicine. 3. On Surgery. 4. On Obstetrics. 5. On Education. 6. On Medical Literature. 7. On Publications. 8. The Code of Ethics adopted by the Philadelphia College of Pharmacy. 9. A Statement in Relation to the United States Naval Medical Corps. 10. A Communication on Hygiene, from the Medical Department of the National Institute. 11. A Statement relative to the Extent to which Drugs are falsified, particular with a View to their Sale in the United States. 13. A Report on the Registration of Births, Marriages, and Deaths. 14. On Indigenous Medical Botany. 15. On the Number of Practitioners in Medicine in Virginia. 16. An Account of a New Feature in the Anatomical Structure of the Genito-Urinary Organs not hitherto described. 17. A Paper on Ophthalmitis Postfebrilis. 18. A Catalogue of the Officers and Permanent Members of the American Medical Association.

The Reports are chiefly in reference to the progress made, especially in the United States, in the various departments to which they refer during the course of the preceding twelvemonths. Attached to some of them we have various papers and statictical documents on subjects of special interest; for instance, appended to the Report of the Committee of Surgery, is an interesting paper on anæsthetic agents, their mode of exhibition and physiological effects, together with

lists of cases in which æther and chloroform had been used in operations performed at several of the hospitals. Appended to the Report of the Committee on Practical Medicine is a valuable paper on "Œdematous Laryngitis, and its treatment by Scarifications of the Glottis and Epiglottis." A similar method had been before proposed by Lisfranc, whose operation we may here refer to—

"Take a long narrow-bladed slightly-curved bistoury in a stiff handle, protected with a strip of linen to within half an inch of the point. Let the patient open his mouth wide, and have the jaws kept apart by means of a cork placed far back between the molar teeth, one end of the cork being held by an assistant. The patient being placed in front of the operator with his head supported against the breast of an assistant, pass the index and middle finger of the left hand into the mouth till they reach the swollen edge of the larynx, glide the bistoury flatwise upon the finger, holding it as you would a pen. On reaching the larynx direct the edge forward and upward, then after having elevated the handle depress it gradually, at the same time pressing gently upon the point. At first, a few punctures only should be made, as by the aid of pressure two or three small incisions are sufficient. They may easily be multiplied in the same way if judged necessary. These scarifications produce a flow of the infiltrated matter and sometimes a slight oozing of blood, which effects a salutary disgorgement. The cough excited by a few drops of serum falling into the larynx, contributes much to diminish the swelling. The immediate beneficial results of the scarifications might be partially defeated, by their occasioning more or less inflammation of the larynx and surrounding parts. In such a case recourse must be had to general or local bleeding, which would soon disperse this traumatic inflammation."

The author of the paper, Dr. Gurdon Buck, jun., of New York, seems, however, to have been unacquainted with Lisfranc's operation, (which he quotes in a note,) until his own paper had been laid before the American Association. He narrates five cases of the disease, in which his own operation was performed. In each of these much and immediate benefit was derived from the scarifications, and in four of them the result was so favourable that the operation of tracheotomy was rendered unnecessary. In one of the cases it became necessary to perform tracheotomy, but the convalescence was in this case much accelerated, the effect of the scarifications in reducing the swelling of the parts about the glottis being such as to allow of the tube being withdrawn from the trachea on the third day.

Drawings of the instruments used, of the modes of employing them, and of the state of the parts under the disease accompany the paper, which is altogether deserving of the attention of the profession.

We have not space to extend our comments farther on this subject. The following extract from the statement of the Naval Medical Corps, illustrating the unprepared state in which candidates occasionally come before the Examining Board, may amuse:—

"Before a recent Board, one gentleman defined a lotion to be 'a kind of application,' and an evaporating lotion 'one which does not evaporate.' Another confessed his ignorance of the freezing and boiling points of water, and contended that knowledge upon such subjects was useless. One candidate determined castor-oil to be the 'oil of castor, an animal.' Another located the solar plexus in the sole of the foot. All these were graduates" ! !

In the Report of the Committee on Medical Literature, some curious instances of classical and other errata are given; they, perhaps, scarcely exceed the following contained in the Report on Indigenous Botany, where we find the Latin word Rumex, usually considered to be a masculine noun, is, if we are to take the writer's ideas of it, eminently epicene. Three species are specially referred to, under the names of Rumex Britannic*a*, R. Obtusifoli*um*, and R. Crisp*us*. What is, however, of far greater importance, is the account given of the medicinal qualities of various species of this genus. The root (of the indigenous kinds,) is usually considered astringent and slightly tonic, but according to the reporter its action is fully equal as an alterative to sarsaparilla "and on account of its laxative qualities, possessing in most cases a decided advantage" over this remedy. We are told that in the Bellevue Hospital at New York it is "very generally used, in a large portion of the venereal, scrofulous, and cutaneous diseases, in conjunction with the preparations of iodine and mercury, as a substitute for sarsaparilla, and with most satisfactory results." Two of the species, namely, the Rumex obtusifolius, and R. crispus, are of common occurrence in this country, and with others of the genus, may, perhaps, be worth the attention of our country practitioners.

Illustrations of the Fraud and Folly of Homœopathy. By Jonathan Toogood, Extra-Licentiate of the Royal College of Physicians, Fellow of the Royal College of Surgeons, &c. &c. London: 1848. 8vo, pp. 26.

A plain straightforward exposition of the follies and absurdities of homœopathy, in which the sterling and sound common sense of the author is brought to bear against the flimsy pretensions with which the advocates of this extraordinary system attempt to conceal its absolute inertness from themselves and their credulous followers. It is, to be sure, like breaking a fly upon a wheel, but the pamphlet cannot fail to be useful if circulated among those who are unable to discriminate, or otherwise in danger of being led away by this or any other specious fallacy which may be presented to them.

Proceedings of Societies.

NORWICH PATHOLOGICAL SOCIETY.

October 12, 1848.

J. G. Crosse, Esq., President.

RUPTURE OF THE UTERUS.

Mr. C. B. Rose, of Swaffham, gave the following particulars of this case:—

M. S., aged 37, at the full period of her third pregnancy, was taken in labour about six o'clock in the morning of Thursday, August 6th; she kept about till noon, when the midwife was sent for, who arrived about 2 p.m., and found the woman lying in bed with strong pains frequently recurring. Upon trying a pain, the midwife discovered a considerable accumulation of the waters. The membranes soon burst, and shortly afterwards she ascertained that the head presented. The pains continuing to return regularly and powerfully without advancing the head within the pelvis, the midwife very properly called in a medical gentleman without further delay, and he arrived about 8 p.m. The woman continued to have strong pains till 10 p.m., but the child's head did not advance, and in consequence, a dose of ergot in powder was administered, also once repeated. Vomiting succeeded these doses, and about midnight her labour pains entirely ceased. Immediately upon the cessation of the pains a great prostration of the woman's powers was observed, accompanied with oppressed breathing and abdominal pain, with which she moaned frequently throughout the night; her pulse also faltered greatly. I was summoned at noon on Friday, and before seeing the poor woman, learned the above history, from which I expressed my strong suspicion that the textures of the womb had given way. Upon going to the patient, I found her pulseless at the wrist, with extremities cold and livid, and abdomen tumid and tender,—in short moribund. An examination per vaginam instructed me that the head was *impacted* at the brim of the pelvis, and that but slight integumental tumour had formed; the touch also led me to believe that the bones of the fœtal head were ossified to an unusual degree, and consequently very unyielding. The os uteri was fully dilated, and had quite receded, with the exception of a portion which was evidently contained between the child's head and the pubis of the mother. The train of symptoms assured me of the mischief that had taken place, but the extremity of the patient made me hesitate in consultation, to recommend her delivery, apprehending that she would die under the operation. Cordials and stimulants had been given, they were now more freely administered, and in half an hour a slight rally being manifest, we determined on delivery. The attending accoucheur endeavoured to perforate the cranium, while I supported the uterus by pressure on its fundus with both hands, but the resistance of the bones was so great that the head receded, evidently passing through the breach in the uterus, (probably making it,) and rested upon the pubis; a considerable quantity of liquor amnii at this time escaped, coloured by a slight hæmorrhage. I now passed my hand into the uterus, to explore and ascertain the state of things, when readily meeting with a foot, I brought it down, and completed the version of the child; the trunk and arms being delivered, the usual steps were taken to bring forward the head, but the cranial bones proved so unaccommodating that my friend applied the forceps, and even then we were obliged to employ powerful traction to effect delivery. We had no trouble in removing the placenta. The uterus contracted well, but the poor creature survived her delivery scarcely half an hour. The child's head was not above the average size, indeed the midwife remarked it to be like her former children's,—they were all of them boys. In the present case the bones were more than usually ossified, and the fontanelles small. Having with considerable difficulty got permission for a *post-mortem* examination, we proceeded next day to the inspection. Upon opening the abdomen, we found a considerable quantity of bloody serum, probably in part liquor amnii, containing portions of coagulable lymph, and also portions of the vernix caseosa, which had separated from the surface of the fœtus. The uterus had fully contracted; its peritoneal coat exhibited patches of lymph adhering, particularly in the vicinity of the laceration, which took place in the anterior part of the neck, and was in a transverse direction. The textures about the rent had evidently been exposed to pressure that had destroyed their integrity.

Mr. Henchman Crowfoot, Vice-President, thought one great error had been the giving of the ergot of rye when the patient had strong pains, and yet there was obstruction to the passage of the head of the child. The rupture in this case appeared chiefly to be confined to the cervix.

Dr. Ranking remarked, with respect to the period of time at which the rupture had taken place, it was his opinion it had followed the administration of the ergot, and did not ensue after the attempts at perforation; nor did he think the head of the child had ever been in the cavity of the abdomen, as the rupture appeared to be below the reflection of the peritoneum. The appearance of the vernix caseosa might have been the effect of a hasty *post-mortem*, it having been previously rubbed off the child in the attempts to perforate.

The President stated, that it had been his misfortune to witness several cases of rupture of the uterus, occurring in different situations. The most rapidly destructive form was that which took place at the fundus, and the fœtus escapes into the cavity of the abdomen. Many cases are recorded of rupture of the uterus that have terminated favourably, where the child has even been delivered back again from the cavity of the abdomen. He thought that the prevalence of certain epidemics, especially erysipelas, had a predisposing tendency to cause rupture of the uterus.

Dr. Copeman suggested, whether it would not have been better to have turned at once, instead of proceeding to perforate, since the head was only just entering the pelvis.

SIMPLE DISLOCATION OF THE ASTRAGALUS: ITS REDUCTION.

The President gave the history of this case, which had been admitted under him in the Norfolk and Norwich Hospital. The patient had been thrown out of a dog-cart, but could give no description of the way in which he fell. Upon his admission the limb presented all the

symptoms of dislocation of the astragalus, the sole of the foot being turned inwards, and the foot resting upon its outer edge, while that end of the astragalus which articulates with the os naviculare, was dislocated upwards and outwards, lying just under the skin. Neither tibia nor fibula were fractured. In reducing it, extension was made from the knee direct, and the heel grasped by assistants, who applied their force in this direction with one hand, the other being placed upon the dorsum of the foot, he at the same time endeavouring to favour the return of the bone by immediate pressure on the dislocated end. To these means it yielded but slightly, and finding the tendo-Achillis very tense, he divided it with a tenotomy knife, and upon resuming the extension, the bone was returned somewhat suddenly into its place after a few minutes, and the shape of the limb quite restored. Chloroform was administered in this case, but not very successfully.

Two casts in plaster of Paris were shown, one taken previous, and the other subsequent, to its reduction, and many members subsequently adjourned to visit the patient in his ward, as he had not yet left the hospital.

CALCULUS.

The Secretary read the notes of a case sent by Mr. Morrell, of Cawston, with a specimen of calculus, taken after death from the bladder of a man 80 years of age. There were three calculi in the bladder, besides a number of small ones in the prostate, but the bladder was in a healthy state. The third lobe of the prostate was somewhat enlarged, and slightly injected, from the stones constantly rubbing against it in the erect position. He had suffered but little inconvenience during life.

Other specimens and drawings were also exhibited.

INQUIRY INTO THE ETIOLOGY OF CHOLERA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The Western Medical and Surgical Society of London, having applied to me by circular to aid them in their investigation of cholera, by obtainiug a complete history of the epidemic as it may exhibit itself in this district, (where, I am thankful to say, it has not yet appeared, notwithstanding that this place figures in the Cholera Report as having twenty-three cases and thirteen deaths, in consequence of the police district of Kensington comprising Uxbridge and the adjoining villages, where the disease prevails,) it has struck me, that a most important branch of the subject,—viz., the etiology of cholera, may be examined with far more facility and accuracy through the co-operation of the members of the Provincial Association, than by any body of men resident in one district or town, whatever amount of talent, zeal, and impartiality they may bring to the task.

In small towns and country villages, where a large proportion of our members practice their profession, the occupation and habits of every inhabitant are well known to his immediate neighbours, if not more extensively: news, particularly bad news, flies apace, and every sick room is filled with gossips, who have canvassed the origin, course, and probable termination of the case, almost before the medical man has seen his patient. The ordinary diet, the privations, and excesses of the sick man, are all known and commented on, and from these officious informants, an intelligent surgeon can, by the exercise of a little discrimination, glean every fact that is necessary to explain the origin of the disease; indeed I have often been struck with the extreme importance attached by non-medical persons, to ascertaining the exact sources of disease, and the care they take in the inquiry.

In London, on the contrary, few persons, even amongst the poor, know anything of their neighbours. Numerous concealed sources of disease exist in foul drains, and ill-ventilated houses and workshops; besides, that even in the case of infectious maladies, it is frequently impossible to trace their origin, though we are certain that the patient must have had communication with contagion in some form. How great a difficulty must then exist in searching for the causes of Asiatic or epidemic cholera, the milder forms of which are not to be distinguished from the sporadic disease, which has always been known to prevail in this country under certain peculiarities of the atmosphere.

The want of precise notions of the etiology of cholera, has always appeared to me to be the great obstacle to a knowledge of its pathology, and consequently, of its treatment, than which nothing can be more unsettled and contradictory of all the objects of medical science. As long as we know not whether this disease arises from malaria,—from foul drains,—from electric states of the earth or air,—from flights of animalcules, or showers of fungous sporules,—from contagion or infection,—or from bad and insufficient food, we cannot decide how the cholera affects the body, or in what manner its essence or effects are to be counteracted by treatment. I would, therefore, beg to propose to the Association, the investigation into the etiology of cholera, not only as an object which, by the constitution of the Society, and the general zeal of its members, it is most peculiarly well qualified to carry out, but also because this is one of those undertakings, on the prosecution of which the Association has founded its claim to the general support of the profession in the provinces, and which it has also in a manner pledged itself to countenance.

In order to execute such a plan, it seems to me desirable to follow the course that was taken with respect to the "Treatment of Burns and Scalds;" and that those members who take an interest in the matter, and have opportunities of observing the outbreak of cholera in their neighbourhoods, should be invited to send replies to certain queries, which replies might either be forwarded at once for publication in the Journal, or be reserved for future comparison and analysis. In furtherance of this object, I beg to subjoin some queries that appear to me to comprise the chief points of such an inquiry; and should my proposal meet with the concurrence of the Association, I shall be most willing to become the recipient of the communications of its members.

Queries respecting the Etiology of Cholera.

1. What was the date of the first case in the district, and the course of the disease?

2. Was communication traceable between the sick and those afterwards attacked?

3. What is the nature of the locality as to aspect, elevation, soil, drainage, and vicinity to water?

4. What was the state of the atmosphere, at the outbreak of the epidemic, as to the temperature, pressure, moisture, electric tension, and the direction of the wind?

5. Was the place of outbreak to windward or leward of marshes, stagnant water, sewers, or any place where the cholera existed?

6. Was the progress of the disease influenced by atmospheric changes?

7. What are the ordinary endemic diseases of the district?

8. Have other complaints assumed a choleric type during the prevalence of the epidemic?

9. Has the average mortality from other diseases been affected by the prevalence of cholera?

10. What was the condition and habits of the first patient?

11. What was his occupation, and the hygienic state of his dwelling and working place?

12. Had he been in communication with cholera patients, directly by visiting them, or indirectly by washing their clothes, attending their funerals &c.?

I am, Sir, your obedient servant,

T. OGIER WARD, M.D., Oxon.

Kensington, Nov. 28, 1848.

THE LAW OF LUNACY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

The following letter was published in the *Morning Chronicle* paper of the 18th instant, in reply to a report of the proceedings of the Society for Promoting the Amendment of the Law, having reference to save contemplated changes in the Law of Lunacy. As the subject is one of great interest to a large class of medical men connected with institutions for the care and treatment of the insane, it is possible you may think the letter worth re-publishing in your Journal.

I am, Sir,

Your obedient servant,

FORBES WINSLOW, M.D.

Sussex House, Hammersmith,

Nov. 20, 1848.

The "Society for Promoting the Amendment of the Law" has had lately under its grave consideration the Law of Lunacy. Your paper of the 14th instant contained a report read by Mr. James Steuart, the secretary of the "Committee on Equity," to whom this question had been submitted. It is much to be lamented that this society did not, before they published the result of their deliberations, place themselves in communication with parties who are supposed, by their professional occupations, to be practically conversant with the operation of the law they propose to amend. If they had adopted this very obvious and natural course, the "Committee on Equity" would have had some reason for self-congratulation. The statement which has been officially published by the secretary of the society is calculated very much to weaken the authority of a body of men having, I believe, the best objects in view. I propose in this letter to notice a few of the inaccuracies contained in the report; for I think, in justice to those who have the care of the insane, the public should not be led away from the truth by any statements of an *ad captandum* character. It is asserted in the report, that "simply on the certificate of two physicians, a person might be condemned to perpetual imprisonment on the charge of insanity." Such, I assure you, is not the fact. I think it was the duty of the society, or of those deputed by them "to get up the case," to obtain accurate information on this point before so seriously committing themselves. No "two physicians" can, of their own authority, commit a person alleged to be insane to an asylum. The act of Parliament expressly forbids it. Surely the "Committee on Equity," or Mr. J. Steuart, the secretary, had the curiosity to look over the provisions of the "Act (8 and 9 Victoria cap. 100,) for the Regulation of the Care and Treatment of Lunatics." If they had done so, they would have seen that, coupled with the certificates of the two qualified practitioners—not being partners—not being relatives of the party said to be insane—not being personally interested in his confinement—there must be a printed "order," filled up and signed by the relative or party authorising the detention of the patient. The certificates are invalid without this "order;" and a party receiving and detaining in his house a patient, on the authority of two physicians only, commits a misdemeanour, and is liable to be seriously punished. It may be said, "Oh, any person will sign the order; that is but a trifling part of the proceeding." But, gentlemen, it makes a very material alteration in your statement. You publish only a portion of the truth; let us have the whole of it. This is necessary before being qualified to form a correct judgment of the existing state of the law. The Act of Parliament is expressly framed for the purpose of obviating, in every possible way, the unjust confinement of persons on the ground of insanity. The two medical men who are required to sign the certificates, are to see the patient apart from each other; they are to state, in detail, the grounds for their opinions, to specify the particular delusions or actions of the party, which, in their opinion, constitute insanity, and such a degree of insanity as to justify a deprivation of liberty. In addition to this, the party receiving the patient, on the "order" and medical certificates, is required to employ a medical gentleman to examine the patient, and this medical man is required by the law to state his opinion of the case, and to forward to the Commissioners within a few days a statement of the bodily and mental condition of the party placed under restraint.* In this way the public has every guarantee against the unjust detention of persons on plea of unsoundness of mind. If a conspiracy exists, the relative so giving the "order," the two medical men filling up the certificate, the medical man who sees and examines the patient after his admission, and the proprietor of the asylum, must be parties. Compare these facts with the allegation—the unfair representation of the "Committee on Equity"—

* If the proprietor of the asylum be a medical man, he is qualified to send in the report.

that "simply on the certificates of two physicians a person might be condemned to perpetual imprisonment on the charge of insanity!" I now come to the question of "perpetual imprisonment." Surely the Commissioners in Lunacy will not feel themselves highly complimented. How absurd is the statement. "Perpetual imprisonment"—the idea is preposterous. Is it likely that if the medical man required to see the patient, is disposed unnecessarily to prolong the confinement of a particular individual, that the commissioners in Lunacy are likely to sanction such a proceeding? They are compelled to visit all licensed establishments, and to examine each inmate, and to discharge those whom they conceive unjustly detained. They may enter a house any day or hour they think proper, at night if necessary; they are empowered to examine witnesses on oath; they never give any intimation of their visit, and every precaution is taken to prevent the possibility of a party being improperly confined on the plea of mental incapacity. I would ask the "committee on equity," whether there does not exist such a legal document as a writ of *habeas corpus?* and whether this does not operate against the possibility of a person being "condemned to perpetual imprisonment" on the charge of insanity? I have had, for the last ten years of my life, constant opportunities of becoming practically acquainted with the operation of the Law of Lunacy; and I can state, having had some hundreds of cases of insanity under my care, that I never saw a medical certificate of insanity which the physician was not fully justified in signing; and, more than this, I have never seen a person consigned to an asylum unjustly. I believe this is the experience of most men connected with institutions for the treatment of the insane. Cases may arise in which the most skilful, cautious, and experienced medical men will be deceived; but they are of rare occurrence. I have, during a long period of my life, been in the habit of visiting the principal public and private asylums for the insane in this country, and I never saw a person confined without good and valid reasons.

The "Committee on Equity" propose, in addition to the two medical certificates, "that it might be advisable, before confining a person on the ground of insanity, to resort to the judges of the county court, or to the magistrates in session, or perhaps call together a small jury to decide upon such cases." The suggestion is altogether impracticable, and must have emanated from a person but little acquainted with the condition of those most frequently consigned to asylums. A party is suddenly seized with a paroxysm of insanity. He is violent, smashing everything within his reach; he may have made an attempt on his own life, or on the lives of those about him. It is essentially necessary, for his own security and the safety of others, that he should, without loss of time, be placed under surveillance, and be protected against his own insane impulses. Picture yourselves carrying such a case before a "judge of a county court," or a "magistrate in session," or "perhaps a small jury," before taking measures to place the patient in a position where his life would be safe, and where immediate medical measures could be adopted to subdue the maniacal excitement. The idea is quixotic! In many of these cases it is a matter of the highest importance to immediately remove the patient from home. The irritation to which a frenzied person would be exposed by bringing him before any judicial tribunal, or "small jury," might possibly endanger his life and greatly increase the violence of his mental excitement. I am certain it would operate injuriously by greatly retarding his recovery. Even in cases where the symptoms were not so acute the course proposed would be highly objectionable. It is not to be supposed that a knowledge of insanity comes by intuition, and that a person, because he happens to be "a judge of a county court," or a "magistrate in sessions," or a member of a "small jury," is qualified *ex cathedra* to detect the delicate shades of disturbed mind, and to pronounce a satisfactory opinion of the competency of a party to control himself or manage his property. In my time I have seen a large jury pronounce a person, unequivocally insane, of sound mind and fit to be at large. I should not, therefore, be disposed to trust to the discrimination of the small jury proposed; that jury could not come to a proper decision without hearing evidence—evidence could not be adduced and witnesses examined without counsel—and, altogether, the inquiry would be very complicated, vexatious, irritating, and unnecessary. If this mode of procedure be adopted, it is my firm belief that many valuable lives would be sacrificed. Take the case of a man who, in a fit of despondency, or under the influence of a delusion known only to himself, makes an attempt at suicide. He fails in effecting his object; his mind rallies; his relatives are, of course, anxious about his safety; two medical men examine him, and give it as their opinion that he ought, for a time, to be under surveillance. The patient manifests no obvious indications, apart from the attempt at suicide, of insanity. He is taken before one of the proposed tribunals and examined. The patient talks rationally, can give reasonable answers to any questions proposed—appears calm and free from excitement. He is pronounced unfit for confinement. In an hour after this wise decision, he may be found weltering in his own blood! It may be urged that I have no right to suppose that such would be the judgment of the tribunal. I know enough of the decisions of juries to feel convinced that a verdict of insanity never can be obtained, unless very strong and conclusive evidence is adduced of the existence of insanity. Cases in which the mind is but slightly impaired, as an incipient insanity, where prompt and early treatment is essential to recovery, a jury would never pronounce in favour of confinement, particularly if the party alleged to be insane protested against it. I cannot, in whatever light it is viewed, conceive a more mischievous "amendment of the law" than that contemplated by the "Committee on Equity." It is not my purpose to enter into the consideration of the other portions of the report. I shall merely observe that the statement put forth exhibits but little knowledge of the subject; and I would humbly suggest, before finally deciding upon what alteration of the law the Society may consider necessary to propose for the sanction of the Legislature, that the "Committee on Equity" should authorize some member of its body to make himself acquainted with the existing operation of the Law of Lunacy, as a preliminary step to any amendment of that law that in their wisdom they may think proper to propose.*

FORBES WINSLOW, M.D.

Sussex House, Hammersmith, Nov. 15, 1848.

* The "Committee on Equity" makes mention of the alleged cruelties practised in private asylums. May I beg their particular attention to the following passage, which I extract from a work recently published, entitled "Thoughts on Severe Diseases of the Human Body," by E. J. Seymour, M.D. Dr. Seymour acted for a period of eight years as one of the Metropolitan Commissioners of Lunacy, and was in the habit of constantly visiting private Lunatic Asylums. This distinguished physician, whose practical knowledge of insanity is not exceeded by any living medical man, observes, in his chapter on "Mental Derangement," "I

MANCHESTER SCHOOL OF MEDICINE.

The annual distribution of prizes to the students of the Pine-Street School of Medicine, Manchester, took place on Thursday, November 9th. The Right Reverend the Lord Bishop of Manchester presided on the occasion; and among those present were the Very Reverend the Dean, the Mayor of Manchester, several of the clergy of the city, and many of the magistrates and aldermen of the borough; together with Drs. Bardsley, Lyon, Fleming, Browne, and Hardy, and Messrs. Thomas Turner, E. R. Stephens, Robert Hunt, Crace Calvert, Heath, and other members of the medical profession.

The Bishop on taking the chair, opened the meeting with an excellent address explanatory of its objects.

Mr. Thomas Turner, after expressing the gratification which he and his colleagues felt at seeing his Lordship in the chair, asked what could the Legislature do for medical reform? Medical reform must rest with the medical profession; and he was certain that the great thing that would reform the profession, would be to give its members a good sound preliminary education. The great point to be aimed at in education was the culture of the heart and the mind, with a view to make men better, and to raise their intellectual powers to the highest possible point of elevation. There would be no difference of opinion that these desiderata should be supplied to all, though the additions to this preliminary education must vary as the pursuits of men in life varied. The Pine-Street School of Medicine had its origin during the time of the late Dr. Percival and Mr. White, and it was afterwards improved by the delivery of detached courses of lectures on anatomy and physiology, mainly by Mr. Gibson, Dr. Roget, the late Mr. Ransome, Mr. Ainsworth, and Mr. Jordan. About twenty-four years ago, however, he (Mr. Turner) became a resident in the town, and after delivering one or two private courses of lectures on physiology, he thought it right to organize a regularly instituted school of medicine in Manchester; concentrating for that purpose all the medical talent which the town possessed. Dr. Dalton took the chair of chemistry; Mr. Ransome that of Surgery; Dr. Jas. Bardsley, that of the practice of physic; and he (Mr. Turner) took the chair of anatomy and physiology, which he still retained. The school had gone on from that time increasing in importance, until at length the College of Surgeons placed it on a footing of equality with the metropolitan institutions. It might now fairly be reckoned one of the institutions of the city; one which was auxiliary in the diffusion of good and the promotion of the cause of suffering humanity. The pursuit of the medical profession was not unalloyed by disagreeable circumstances. When a man had devoted his fortune and his time, and had incurred the risk of his health and of his life in unravelling the intricacies of science, with the view to their application to the benefit of mankind, was it not painful to him to see his position in society, and the hold which he ought to have on the public opinion, usurped by empiricism and by impudent pretenders to the cure of disease? He was not seeking to elicit their sympathy on account of the established medical practitioners, but on account of the students, in whose prospects he felt deeply interested. Let them not, however, be discouraged, but let them remember the advice given them by the Lord Bishop, and ask themselves whether the medical profession was really at a discount,—whether it had really been lowered in public estimation? Upon pressing occasions, their advice was sought by the legislature and by all public institutions; there was not an individual, rich or poor, high or low, who was not constantly offering up a debt of gratitude to the medical profession, for the blessings which it conferred upon them. To the junior members of the profession and the students who were there assembled, he would say that they would often be appealed to, and let that appeal never be made in vain. That was the character which had hitherto been sustained by the medical men in Manchester, and he felt persuaded that the city highly applauded such attempts on their part at the amelioration of the condition of the people, made without the prospect of any further reward than that which a pure conscience must give to him who does his duty. No one had ever seen anything like fear on the part of medical men when called upon to do their duty; temerity rather than timidity was their characteristic. The medical school would have been unworthy of the patronage of so many distinguished individuals as he saw around him, had its promoters limited their endeavours merely to a professional or medical education. The course of training which they had established had been, as much as in them lay, moral as well as professional; they had endeavoured by every means in their power to direct the minds of the students even unto the higher principles of thought and conduct. An implication of scepticism had been cast upon the medical profession, but he hoped that it was utterly false. It was strange to him how a medical man could be a sceptic, since the book which he had to study was nature, every chapter of which indicated the existence of a God. He would appeal to the clergymen present whether they had not, when visiting the bed of sickness, received the greatest possible amount of assistance from the medical attendant.

The following prizes were then distributed, being handed to the students by his Lordship:—

Gold Medal.—Mr. J. O. Fletcher.

Anatomy and Physiology.—(Mr. Turner)—*Silver Medal:* Mr. J. O. Fletcher. 2nd Prize: Mr. Adam Hampson, of Bolton.

Surgery.—(Mr. Ransome.) 1st Prize: Mr. R. A. Gaskell, of St Helens. 2nd Prize: Mr. John Earnshaw, of Clitheroe.

Principles and Practice of Midwifery.—(Mr. Heath.) 1st Prize: Mr. R. A. Gaskell; 2nd Prize: Mr. Wm. Henry Broadbent, of Altrincham.

Materia Medica.—(Dr. Ainsworth)—*Silver Medal:* Mr. Wm. Derbyshire, Stockport.

Chemistry.—(Mr. F. C. Calvert.) 1st and 2nd Prizes: Mr. Mark Rowland Day.

Anatomy and Diseases of the Eye.—(Mr. Hunt)—*Silver Medal:* Mr. John Earnshaw.

Botany.—(Dr. Hardy and Mr. Just.) 1st Prize: Mr. Wm. Henry Broadbent.

Forensic Medicine.—(Dr. Browne)—*Silver Medal:* Mr. William Henry Broadbent.

General Pathology and Morbid Anatomy.—(Mr. E. R. Stephens)—Mr. H. Thornton, Dewsbury.

---

must in common justice premise, that during my period of duty as a Commissioner of Lunacy, I never witnessed one case of cruelty. The greatest care was taken, the most assiduous, nay, the most invidious (to innocent people) inquiries were made. Every suspicious case was examined on evidence, and never any case of cruelty, nor any thing like it, occurred."—p. 217. Since this physician resigned the post of commissioner, private asylums have been placed under much stricter supervision, and, of course, there exists less opportunity for the alleged "cruelties."

PRINCIPLES AND PRACTICE OF MEDICINE.—(The late Dr. Howard.) 1st Prize: Mr. J. O Fletcher. 2nd Prize: Mr. Earnshaw.

Mr. Hunt then handed to his Lordship for distribution, the certificates of honour for regularity of attendance and general good conduct during the session. His Lordship distributed them to the following gentlemen:—

Messrs. Samuel Taylor, Bolton; John Earnshaw, Clitheroe; Edward Akers, Halifax; William Henry Thornton, Thornhill, near Dewsbury; William Henry Broadbent, Altrincham; Patrick Murphy, Manchester; John Wardleworth, Bury; Richard Allanson Gaskell, St. Helens; Joseph Foster, West Indies; William Bagley Clarke, London; Jas. O. Fletcher, Manchester; John Wright Baker, Derby; W. Aspinall, Haslingden; Mark Rowland Day, Selby, Yorkshire; W. Chapman, Sedbergh, Yorkshire; Edmund G. Goulden, Hazle Grove; Charles Tysoe Harvey, Salford; William Jay Williams, Manchester; David Russell, Leith, Scotland; Robert Marsland, Lostock, Stretford; Robert Slater, Manchester; Edmund Manley, Tyldesley; George Purcell, Manchester; John Doxon Ward, Chorlton-on-Medlock; Adam Hampson, Bolton; Charles W. S. Large, Camberwell; John Hancock Wolstenholme, Bolton.

Resolutions of thanks to various benefactors of the Institution, to the medical charities of the town, &c., &c., were severally moved and seconded by Mr. Turner, the Rev. H. Stowell; the Rev. Nicholas Gernon, Dr. Fleming; the Rev. Dr. Vaughan, Mr. R. Brandt; Mr. Hunt; Mr. W. Brown, M.P., and Mr. Brotherton, M.P.

THE PUBLIC HEALTH BILL.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

It cannot be doubted but that the stability of what is called the British constitution, greatly depends on the caution of the Anglo-Saxon character. One of the chief elements of this intellect is an unwillingness to disturb any existing arrangements which work tolerably well, and a disbelief in plans, however specious, which have not been previously tried. This has its disadvantages in the perpetuation of many worn-out institutions, but on the other hand it has its great advantages in not rashly experimentizing with great national interests. And, if we look at this British nation as an individual man, we shall see the nation practising those common-sense principles which in the individual raises him to prosperity. For the successful man, as a rule, is not the one that risks all, but who risks nothing, who is not in a haste to be rich, but who, by prudence and caution, and by deliberation in all his proceedings, rises from particulars to generals, adopting in his rule of life the Baconian theory of induction. Bearing these very obvious remarks in mind, will greatly obviate many of the objections of the medical press to the recent legislation on public health. The act for promoting public health, may not be that complete legislative enactment which we may wish, but it is the cautious beginning of a more perfect measure,—the tentative step towards one of the most important goals which have ever been seen in the dim distance. Let us not, therefore, judge it as if perfect in itself;—let us not be annoyed because our own profession is not sufficiently recognized in it. It will be in time. Amended acts will follow. It is a great thing that Parliament has legislated on the subject at all, and that the active benevolence, the candour, and *bonhommie* of Lord Morpeth, has induced the House to carry an entirely new measure, on a totally new branch of legislation.

If we candidly reflect, we have not done much, as a profession, to investigate the great causes of disease in this country, and we are greatly indebted to the energy of Mr. Chadwick for forcing upon our observation the noxious influences of filth. He has taken up this subject with the perseverance and ability by which alone great good is accomplished; and although he may be a little one-sided in some of his views, yet on the whole he is a per-seeing and clear-sighted man, bent on carrying out practically, and on a great scale, the purification of this country from the most obvious causes of disease. It is as unwise for us to be annoyed at a non-medical man carrying out sanitary principles, as it is for the educationists to grumble at a physician (Dr. Kaye Shuttleworth,) carrying out a grand scheme of education. All who know any thing of the mechanism of great social movements, are aware that single individuals are the main-springs. Chadwick and Shuttleworth are such main-springs; each of an important change, by which the mental and physical health and energy of the arising generations will be greatly improved. Let us not, therefore, throw any obstacle whatever in the path of sanitary improvements. Our profession is a self-denying one. It does more for the poor of this couutry without any reward than any other body of men. And if these gratuitous services were only given more generally in the right spirit, without any hope or expectation of reward, except in that reward which duty well performed gives to the individual conscience, we should stand as high in public estimation as our profession deserves, and there would not be the complaint, that although individual members of medical profession are held in high honour, yet that the body, as a body, is not.

Yours obediently,

M.D.

PROFESSOR OWEN AND THE SANITARY COMMISSION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In my article on the Sanitary Commission and the Board of Health, published in your Journal of November 15th, there occur two errors, which I will thank you to allow me to correct. The first is merely typographical. Egypt is called the "faithful," instead of the "*fruitful*," mother of pestilential disease. The second is of more importance, and I am anxious to acknowledge a mistake respecting Professor Owen, for whose attainments I have the greatest possible respect, and which I think I have

duly recognized in placing him in scientific rank next to Cuvier himself. As I had the pleasure of hearing the last course of lectures delivered by this illustrious comparative anatomist, I still retain veneration enough to reserve the first place for him. Professor Owen was not engaged in the Irish potato enquiry at all, and although one of the Sanitary Commissioners, I imagine the association of a name so illustrious in anatomical science was an important desideratum for the real compilers of a document so replete with questionable medical doctrines. The absence of Professor Owen from the Potato-Commission does not, however, touch in the slightest degree the main points of my criticisms; but the acknowledgment of an inadvertent error, in a merely personal allusion, though it may blunt the force of a little sarcasm, is too sacred a duty for me to omit as soon as it was pointed out to me.

I am, Sir,

Your obedient servant,

E. O. SPOONER.

Blandford, Nov. 29, 1848.

CONTAGIOUSNESS OF CHOLERA: PROFESSOR OWEN AND THE SANITARY COMMISSION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In the last number of your Journal you have inserted extracts from a Report of Mr. Spooner, read before the Dorchester Medical Society. The main object of this paper is to shew that the "Asiatic Cholera" is contagious; and that the contrary belief now generally advocated by medical men, is fraught with danger, inasmuch as it has led to the relaxation of the quarantine laws and other precautionary measures. This change in medical opinion, Mr. Spooner thinks, is owing to the cupidity of merchants. "The mercantile world," he says, "in its lust for rapid accumulation has employed medical talent to disprove the logic of history and human experience."

This gratuitous charge of venality against the medical profession is, I apprehend unfounded. The altered views on the doctrine of infection result not from this sordid motive, but from more extended observation and facts, a more correct and comprehensive survey of the nature and laws of contagion; as well as of the cause of zymotic diseases in general. The Board of Health has collected a body of evidence from all parts of the world to prove that, except under peculiar circumstances, the "Asiatic Cholera" is not propagated from a diseased body to a healthy one; and in promulgating this opinion they have done wisely, inasmuch as the contrary belief, if fallacious, "diverts attention from the source of danger and the real means of protection, fixes it on those which are imaginary, creates panic, and leads to the neglect and abandonment of the sick."

Mr. Spooner is equally free in his strictures on the individual members of the Board of Health as he is on the profession generally. He thinks the Government has acted unwisely in selecting such men as Professor Owen and Dr. Southwood Smith; and that a better choice would have been made had Dr. Watson, Dr. Paris, and other names equally honoured and revered, been placed on this Commission. From his own shewing, however, this would have been impossible, unless, these distinguished physicians had relinquished their practice; for he states, "what between the time Mr. Owen lost last year, in tracing out the potato-disease in Ireland, from which commission I imagine the public had the felicity of learning nothing; and the time this year sacrificed in architectural studies respecting the best shape of drain-pipes and effluvia-traps, pure surgery will reap but little advantage from the lucubrations of this peripatetic philosopher." It is needless to state, since it is so generally known, that Professor Owen had nothing whatever to do directly or indirectly, with the Potato-Commission in Ireland; and it is equally unnecessary to advert to the correctness and good taste of the other remarks. I cannot but regard them, however, as misplaced in your ably conducted miscellany. A prurient desire to attack the reputation of others, is but too common in the other weekly medical journals, and it is with the wish to deprecate the insertion of these attacks in yours, and not to defend Professor Owen that I venture to trouble you with this note. Professor Owen cannot be injured by such assailants; his character stands pre-eminent throughout the civilized world, and in those departments of science to which he has directed his talents, he is confessedly without a rival. The Ministers have shown great sagacity in selecting Professor Owen and Dr. Southwood Smith for so important a measure as the sanitary improvement of the country; and the appointment is as satisfactory and beneficial to the public, as it is creditable to them.

It is indeed most fortunate that men with so much originality and comprehensiveness of mind, should undertake this trust and be able to devote their time and energies to it, without sacrificing their other professional duties.

I remain Sir,

Your obedient servant,

THOMAS POYSER, F.R.C.S.

Wirksworth, Nov. 23, 1848.

Medical Intelligence.

PROPOSAL TO CHANGE THE FORM OF HOSPITALS.

Every one acquainted with hospital-practice, whether obstetric, surgical, or medical, is well aware of the great liability among the patients to febrile and inflammatory attacks whenever the wards are overcrowded. I believe there are few or no circumstances which would contribute more to save surgical and obstetric patients from phlebitic and other analogous disorders, than a total change in the present system of hospital practice. I have often stated and taught, that if our present medical, surgical, and obstetric hospitals were changed from being crowded palaces with a layer of sick in each flat, into villages or cottages, with one, or at most two patients in each room, a great saving of human life would be effected. And if the village were constructed of iron (as is now sometimes done for other purposes,) instead of brick or stone, it could be taken down and rebuilt every few years; a matter apparently of much moment in hospital hygiene.

Besides, the value of the material would not greatly deteriorate from use; the principal outlay would be in the first cost of it. It could be erected in any vacant space or spaces of ground, within or around a city, that chanced to be unoccupied; and, in cases of epidemics, the accommodation could always be at once and readily increased.—*Dr. Simpson* in *Monthly Journal for November.*

APPOINTMENTS.

W. S. Kirkes, M.D., has been appointed Medical Registrar and Demonstrator of Morbid Anatomy, at St. Bartholomew's Hospital.

Robert Ebenezer Brown, M.D., has been appointed Colonial Surgeon for her Majesty's fleets and settlements on the Gold Coast.

ROYAL SOCIETY.

At the Anniversary Meeting, held November 30th, the Earl of Rosse was elected President for the ensuing year, Samuel Hunter Christie, Esq., and Thomas Bell, Esq., Secretaries. Sir James Clark, Bart., William Allen Miller, M.D., Richard Owen, Esq., and Peter Mark Roget, M.D., are among the Members of the Council.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members, November —:— A. H. Daniell; C. T. Harvey; W. W. Scholefield; C. W. Morris; J. Williams; W. Hewitson; R. Barnes; A. D. Dunstan; G. T. Cooper; W. L. Howard.

Gentlemen admitted Members on Friday, Nov. 24:— J. Carroll; J. T. Watson; C. Creed; R. T. Deakins; S. Churchill; W. Maltby; T. Venn; W. B. Clapham.

Gentlemen admitted Members, Friday, Dec. 1st.:— A. Brooks; R. Senior; J. J. A. Dirham; T. Jeston; C. W. Whitby; J. Russell; T. Hughes; R. T. E. Cooke; J. Duff; H. Potter; P. J. Elborough.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, Nov. 23rd:—Henry Julian, Harefield, near Uxbridge; Thos. Walker, Wakefield; John William Billing, Steggall, London; Robert Powell, Bristol.

Gentlemen admitted Members on Thursday, Nov. 30th:—Edward Ilott, Bromley, Kent; John Edward Elam, Leeds.

OBITUARY.

Died, November 18th, at Long Langton, near Blandford, aged 79, George Crosse, Esq., formerly Surgeon to the Royal Dragoons.

November 22nd, at Brompton, aged 32, George Hines Young, Esq., surgeon.

November 29th, in Chester Place, aged 41, Charles Buller, Esq., M.P., President of the Poor-Law Board.

November 30th, at Kensington, aged 66, John Hooper, Esq., Surgeon.

December 2nd, at Shepperton, aged 67, Samuel Cooper, Esq., F.R.S., late President of the Royal College of Surgeons, and Professor of Surgery at University College, London.

December 3rd, at Beckenham, aged 78, James Scott, Esq., formerly of Bromley, Kent.

December 5th, in Wimpole Street, aged 52, John Clendining, M.D., F.R.S., Fellow of the Royal College of Physicians, Physician to St. Mary-le-bone Infirmary.

BOOKS RECEIVED.

Chemistry, as exemplifying the Wisdom and Beneficence of God. By George Fownes, F.R.S., Professor of Practical Chemistry in University College, London. Second Edition. London: Churchill. 1849. pp. 160.

Observations upon Bulam, Vomito-Negro, or Yellow Fever, with a Review of "A Report upon the Diseases of the African Coast, by Sir William Burnett and Dr. Bryson," proving its Highly Contagious Powers. By Sir William Pym, K.C.H., Inspector-General of Army Hospitals, and Superintendent-General of Quarantine. London: Churchill. 1848. pp. 311.

A Treatise on the Diseases of the Heart and Great Vessels, &c. By J. Hope, M.D., F.R.S., &c. Fourth Edition. London: Churchill. 1849. 8vo. pp. 611.

Diet and Cholera, &c. By William Barnard Boddy, Surgeon, &c. London: Highley. 1848. 8vo. pp. 40.

A Treatise on the Cure of Ulcers by Fumigation. By George Alfred Walker, Surgeon. London: Longmans; Highley, &c. 1847. 8vo. pp. 112. Plates.

Surgical Experience in Chloroform. By James Miller, F.R.S.E., F.R.C.S.E., Surgeon in Ordinary for Scotland, to Her Majesty and to His Royal Highness Prince Albert, Professor of Surgery in the University of Edinburgh, Senior Surgeon to the Royal Infirmary, &c. &c. Edinburgh: Sutherland and Knox. 1848. 8vo. pp. 60.

An Essay on the Teeth. By Augustus Cook. London: Churchill. 1848. pp. 75.

Lectures on the Actual Condition of the Metropolitan Grave Yards. By George Alfred Walker, Surgeon, &c. London: Longmans; Highley. 1847. 8vo.

A Practical Treatise on the Domestic Management and most important Diseases of Advanced Life. By George E. Day, M.D., Fellow of the Royal College of Physicians, &c. London: Boone. 1849. 8vo. pp. 342.

A Critical Treatise on the General Paralysis of the Insane. By James M. Wynn, M.D., Physician to the Royal Cornwall Infirmary, &c. London: Churchill. 1848. 8vo. pp. 50.

TO CORRESPONDENTS.

Communications have been received from Dr. Forbes Winslow; Dr. C. W. Bell; Dr. T. O. Ward; Mr. T. Poyser; Mr. E. O. Spooner; Mr. S. S. Dyer; Dr. Thomson; Mr. Page; the Sheffield Medical Society.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.

MEDICAL & SURGICAL JOURNAL.

LECTURE ON THE NATURE & TREATMENT OF CHOLERA,

CONSIDERED WITH REFERENCE TO ITS

ANALOGY WITH CONGESTIVE AGUES OF QUOTIDIAN TYPE.

By CHARLES W. BELL, M.D., K.L.S.,

Physician to the Manchester Royal Infirmary, &c, late Physician to Her Majesty's Embassy, in Persia, &c., &c.

(Read before the Medical Staff of the Manchester Royal Infirmary, and the Members of the Medical Profession in Manchester, November 3rd, 1848.)

LECTURE II.*

Little now remains to be said with regard to the nature of cholera, if I have succeeded in convincing you that the disease does not exist essentially in the blood, but in disordered function of the nerves and blood-vessels, and if my arguments have carried any conviction of the truth of the following points—

1st. That an attack of cholera begins, and essentially consists, in disordered capillary circulation.

2nd. That congestion is the effect of this condition, and the cause of the other symptoms, and of death.

3rd. That the diarrhœa is a natural mode of relief to congestion, and thereby tends to the prolongation of life, and that being an exudation, it is not controllable by means applicable to excretion.

4th. That each period of twenty-four hours, in every attack of cholera (which extends beyond that period,) is marked by—1st. A period of capillary disturbance. 2nd. A period of congestion. 3rd. A period of comparative capillary relaxation and partial reaction; and, 4th. A period of renewed capillary disturbance and congestion, commencing at the expiration of twenty-four hours; not from the first purging, but from the first effect of the influence in capillary disturbance; and if the case proceed onwards without death or cure, that similar changes may be traced (often notwithstanding very active interference,) in the two subsequent periods of twenty-four hours each.

5th. Which I have rather asserted from observation, than attempted to assign any reason for, that the fourth day after the occurrence of algide symptoms is not characterized by the return of a distinct stage of congestion, but that the disease then goes on to consecutive fever.

* Continued from page 681.

It was my original intention to have selected cases from published works, by writers of authority, to illustrate these points, and to show by examples how the natural stages of the disease may be mistaken for the effects of treatment; to illustrate the evils of bleeding from an artery, or of mistimed venesection, in producing collapse; the injurious influence of stimulants and opium; the torments induced by hot applications; the effect of calomel in causing consecutive fever, &c.; but this course might appear invidious, and I am satisfied would be unnecessary, for it appears to me that a very small proportion of well-recorded cases of cholera will be found which do not bear on one or more of these five points, and to this test I most willingly submit the opinions which I have attempted to inculcate with regard to its nature and treatment, always providing, however, that due allowance be made in applying the test for the effects of any treatment that is consistent with the views here advocated.

Let us now proceed to consider some of the more practical points of the treatment of cholera, especially in reference to HEAT AND STIMULANTS.

When the body is cold and exhibits so great a want of energy in the cuticular capillaries, the most obvious means of removing this condition which suggest themselves to every one are external heat and diffusible stimulants; but as these are not at all times attended with the beneficial effects that might have been anticipated, it is necessary to examine the reason of this failure by enquiring into the particular nature of the object to be gained. Finding that the disturbance of vital action commences in the capillary circulation, and not in the heart, it would appear that to begin by stimulating the heart is to begin at the wrong end of the chain of actions, and that to fulfil the indication some means is required that will act by giving power to the capillary circulation, independently of the heart's action.

Unfortunately all the medicines usually classed as stimulants excite the capillary circulation only by exciting the heart's action; secondarily and slightly, by sympathy with the heart; but principally in consequence of the distension produced by the increased force with which blood is injected into these vessels; for to them, as to the heart, distension is the most direct means of exciting irritability and action; but if these vessels are not distended, capillary action is not directly excited by exciting the heart.

In the stage of congestion in cholera, we have endeavoured to shew that this increased propulsion of arterial blood does not take place, for the quantity of arterial blood in the system is diminished by the lungs opposing the free transmission of blood to the left side of the heart. We have shewn, that so soon as congestion commences, the heart becomes excited by its most powerful stimulus,—viz., distension of its cavities, at least on the right side, but that its action is opposed by the condition of the pulmonary vessels, and oppressed by the accumulation of venous blood from the extremities; it is evident, then, that to add stimulus to that which is already excited to the utmost in vain, can do no good, unless it can add power, but as it cannot do so in this condition, stimulus can only exhaust the irritability of the muscle, but not propel arterial blood in the quantity necessary to distend and excite the capillaries. If the power of the heart have not been yet excited to the utmost, a stimulant may prove useful by urging it to still greater exertions to overcome the obstruction, but if already excited in vain, it is quite evident that additional excitement can only do harm, by producing exhaustion of muscular power. If, however, we have reason to believe, that by-and-by the obstruction to the heart's action by the capillaries of the lungs, and impulsion of blood upon it from the veins, will both gradually cease, at least in some degree, it will be evident, that if it only retain sufficient power, the heart will then be in a condition to restore the circulation to a more normal state, and therefore that our efforts should be directed to husband the power of the heart, instead of exhausting it; but the only means of doing so consistent with the maintenance of sufficient systemic circulation, is to endeavour by every possible means to promote capillary action, and so to diminish the labour of the heart by removing the obstruction to its efforts, not by subduing the excitement of the heart by opiates. The whole question, therefore, lies in the means of doing this. We have shewn that when opportunity offers,—that is while the powers of the heart are as yet unexhausted, and its irritability unimpaired,—this may be accomplished by freely opening the veins of both arms, thereby soliciting the blood from the extremities, and relieving the heart from part at least of its oppression *a tergo*, but both experience and reason have warned us against attempting this after the heart has been too long subjected to excitement. What then is our resource in this condition? This is exactly the point which the long history of disease that I have submitted to you is intended to illustrate,—viz., that we actually possess medicines which have the power of stimulating and fortifying the capillary circulation without first exciting the heart's action. Many of the preceding remarks have been directed to show that the action of antiperiodic medicines is of this nature, only that as the morbid effects evinced in periodical disease of different types are not identical, neither can the antidotal effect required from medicine be identical. I have endeavoured to point out that, although quinine alone does no good in these diseases, the combination of quinine with iron has proved in my own experience to possess this power in quotidian ague and in cholera, in a very remarkable degree. I have found it check the vomiting and purging often in a few minutes, and gradually restore the circulation and warmth, and the secretions, without the assistance of any other applications, not, be it remarked, by exerting an astringent effect in moderating the diarrhœa, for it proved equally useful whether this symptom existed or not, but by removing the cause in the disorder of the capillary circulation.

But it is not enough to consider a question of so much importance as that of the use of heat and stimulants merely theoretically; I must, therefore, add my testimony to that of many authors against the use of diffusible stimuli where congestion is fully established. I have tried it carefully, and anxiously watched the result of each dose with my ear to the heart, and I can positively assert that each dose, in cases where congestion has reached to a dangerous degree, is attended with increase of all the symptoms, dangers, and sufferings attending congestion.

The first time I was myself attacked with cholera, the symptoms were at once arrested by a glass of brandy taken on the first occurrence of the blueness, purging, and cramps, because congestion, being at once relieved by the diarrhœa, had not reached the point of oppressing the heart's action, and the stimulant aided the action of the heart to excite the capillaries; but on my second attack, the effect of this stimulant was very different, and excessively painful and suffocating, because not being relieved by diarrhœa, the congestion at once attacked the vital functions, and I was obliged to have recourse to quinine and iron, which soon relieved the suffocation.

The case in which I had the best opportunity of carefully studying this effect of stimulants was that of the late Chief Physician of Persia, a native of that country, who had been educated at St. George's Hospital, London, and an intense admirer of calomel. His attack was not one of pure cholera in its usual form, with purging and vomiting, for he was one of the earliest sufferers from the disease, while the digestive organs were as yet seldom affected, and when it presented many of the characteristics of ague. I attended him as an intimate friend, night and day, although no persuasions could induce him to try either the medicines I recommended, or bleeding. He felt so bilious that he was sure nothing would do but calomel. His attack lasted for several days, in each of which, the cold stage that at first was followed by return of warmth, was more prolonged, till at length intermission ceased; the relief which was denied by the bowels was here effected by the skin, and the quantity of ice-cold watery exudation with which all the body but the breast was constantly bedewed, proved the rapidity with which the iced-water he was incessantly imbibing was both absorbed and exuded. He was much colder than I have ever found cholera patients in whom the characteristic diarrhœa existed. After resisting every proposal I made for treatment, he at length consented to try stimulants, for it appeared he was determined to die a martyr to medical prejudice, accordingly, I administered to him large doses of æther and alcohol. After each dose, on

applying my ear to the heart, I heard a sudden increase of confusion in its action, a sort of indescribable churning sound, as if it would burst,—not as if it were getting rid of its contents, but rather constantly agitating the same portion of fluid,—and at each fresh effort of this sort, the icy exudation from the skin burst forth in redoubled quantity. I repeated this experiment until I had again and again proved the effects, and then, as in doing so, it was plain that more harm than good resulted, I left the case to nature, determined to watch the symptoms as they proceeded. It was not till the last day that the brain became materially affected, although, in the course of four or five days, I am certain not above half a pint of urine was secreted; he then became insensible, the pulse became imperceptible, and at night, being seized with fearful tetanic convulsions, which lasted for two or three hours, he died. The first case of cholera, with purging, occurred on the day of his death in the next house, in a child, and was fatal in two or three hours.

This effect of stimulants in a congestive disease so very nearly allied to cholera, completely confirmed what I had formerly seen of the result of their exhibition in the more common form of cholera at home, insomuch that I have not since been tempted to repeat the experiment unless conjoined with bleeding, or in the very first moments of an attack, when there can be no doubt of their efficacy, or that of any other means of inducing an impression calculated to rouse the sympathetic through any single function, to a perception of its other natural stimuli.

A diffusible stimulant can, therefore, only do good while the heart possesses more power than has yet been called into action, or before it has yet become so completely oppressed as to be unable to respond effectually to the stimulus. The same reasoning might be applied to the question of using external heat as a stimulus, for though heat and pain are as powerful excitants to local action as brandy to the stomach, they unfortunately also act directly as stimulants of the heart's action. Difficult, however, as it may be to explain their effects, I feel bound, in conjunction with many others of great practical experience, to protest against the use of both, when the case has reached the stage of confirmed congestion; for though in the preceding period, external heat may be as useful as a diffusible stimulus, it is not less injurious in the second. On this subject I cannot do better than quote from one of our most recent authorities:—Mr. Parkes says, "Warm baths, vapour baths, and warmth applied in any way to the surface, never appeared to me to be of the slightest service in true cholera; the spasms were sometimes relieved, but the algide symptoms were almost invariably increased. The depressing effects of the warm bath were sometimes marked and unmistakeable; I have seen a man walk firmly to the bath, with a pulse of tolerable volume, and a cool, but not cold surface, and in five or ten minutes, have seen the same man carried from the bath with a pulse almost imperceptible, and a cold and clammy skin."

These remarks perfectly coincide with my own experience of external heat. I have used the hot-air bath, so much recommended in this country, to such an extent as even to scorch the skin, without producing the slightest reaction, but apparently the worst effect, and have searched in vain for an excuse for the torture to which so many patients have been subjected by such attempts to restore warmth. These would not have been cruelty, whatever the sufferings, if really beneficial; but I am now convinced of the contrary, and that they are not only useless, but injurious. Without knowing more of the actions which take place in the systemic capillaries in health, and their changed operation in this disease, it is impossible to account for these injurious effects, unless by excitement of the heart, or on the principle which prevents us applying heat to a frozen limb, to which the condition of the circulation is somewhat analogous; practically I have come to the conclusion that external heat is always injurious when congestion is extreme. In my opinion, *medio tutissimus ibis* in this respect, and that it is better to be content with a moderate temperature in the room, sufficient to promote any tendency to reaction, but not to force it.

The question, however, is one of no mean importance,—whether if we are not to yield to our natural impressions regarding the necessity of restoring warmth, we may not cede to the adjurations of the patient to indulge him with cold? This is a question which I am not bold enough to decide. There is I think much more evidence in favour of cold than of heat, yet both may be wrong, and according to my own experience both extremes are unnecessary. One friend writes to me from Tehran, that his practice of immersing the patient to the neck in cold water, till reaction took place, was very successful; another that he cured his patient with frictions with snow, in Erzeroom, where the cholera occurred in the winter season, and where the cold is intense. In Russia, and in Hamburgh, iced drinks have been much used. I am well acquinted with two Persian gentlemen, who were laid out for dead, in the cholera of 1829, but who recovered on being washed in the open court-yard in a winter's night, as a preparation for interment, with water, to obtain which the ice had to be broken, and I was once called to the public burial ground of the city to see a dead man whose veins had begun to bleed while they were washing his body. The man, it appeared, had been attacked with one of those forms of disease already alluded to—a species of cholera without purging—had dropped down as if struck with appoplexy; an attempt had been made to bleed him in both arms without success, he was left for dead and carried off for interment, when what I have related occurred on his being deluged with cold water; unfortunately no one had presence of mind to bind up his arms and protect him from the cold, and he was really dead when I arrived. These are strong arguments for the use of cold, but may perhaps be met by equally convincing arguments against it. I look upon these as instances of powerful nervous impression made at a suitable stage of the disease, and that if the remarks formerly made of the *post-mortem* return of heat in the corpse be attended to, no such accidents can arise as those fearful cases sometimes mentioned of persons

being buried alive. If one, apparently dead of cholera, become warm from the extremities upwards, no doubt of death can exist, and no chance of recovery; if this does not take place, or, on the contrary, if warmth proceed from the trunk to the extremities, there is a possibility that he may be alive.

I consider the question of the excessive external application of heat as fully determined in the negative in the congestive stage, but open to a certain degree in that which succeeds it, and that the question of cold applications is still *sub judice*, and subject to objection in the stage succeeding congestion, which, however, is so difficult to fix precisely, that both extremes are better avoided, especially as I am convinced that treatment conducted on other principles will almost always prove successful without either.

Now, with respect to the DIARRHŒA,—enough has formerly been said on this subject to show that it has been considered rather as a means of relief to congestion, than in itself a source of danger, as tending to prolong life, rather than as the cause of death in cholera, insomuch, that even if we had it in our power to check it by a word, it is a word which we should hesitate to pronounce, unless we were assured that the cause rather than the effect would be influenced. If then it is to be considered in itself as rather a good than an evil, it must, nevertheless, be always looked upon as a sign of imminent peril to life, which, as its direct restraint would endanger immediate collapse, should the more impress us with the necessity of removing its cause without delay; for when the disease is in the neighbourhood, and sudden evacuation of this kind occurs, even though not another symptom of cholera be present, the case is to be considered one of cholera. It is not a secretion from the bowels, for that is a vital action of the capillaries; this is the very reverse—an exudation, showing that the capillaries of the bowels have succumbed to the same cause of impaired action which we have throughout considered essential to the disease. The capillaries of the skin may yet perform their functions, the disorder may be almost local in the bowels, but it is essential, and were it possible by ligature, or any mechanical means, to arrest the exudation, without arresting its cause, it is scarcely possible to doubt that the effect would be congestion and oppression to the heart; that this would be attended with diminished circulation of arterial blood, and impaired powers in the whole system, which would then succumb to the anti-vital influence, and terminate in collapse. To what purpose then would we use mere astringents to check the diarrhœa? Have we not rather reason to congratulate ourselves that such means are for the most part wholly inoperative? In the perusal of cases it is impossible not to be struck with the complacency with which the authors seem to regard the effect of pills of lead and opium, chalk mixtures, catechu, &c., when administered at the very period of the disease, in which we should naturally expect to find congestion on the decline, (if the disease be really one of quotidian periodicity,) an effect which, if real, instead of apparent, would only be to be deplored. If, however, we check the diarrhœa, by removing the cause, restore their wonted action to the capillaries, and thereby prevent the effect of their disturbance, we cure, rather than restrain, the diarrhœa. Here, however, a difficulty meets us; the congested condition of the vessels, and their reverse current of blood, afford very obvious reasons for expecting but little effect from any medicine that can act only by absorption into the blood from the alimentary canal; nevertheless, experience proves that absorption does take place to a degree much greater than might have been anticipated. However great the amount of exudation of the fluid of the blood into the intestines, this occurs only at intervals, and paradoxical as it may appear, while the congestion continues unrelieved, there seems to be a great tendency to restore fluid to the blood, during these intervals. Sufficient evidence of the absorption of salts in solution, in the fluids of which the patient drinks with such avidity, is to be found in the fact, that tartar emetic produces its effects when given in this manner, and those I have so often witnessed from quinine and iron, given in weak solution, have been so immediate, as to excite my astonishment. Thirty drops of muriated tincture of iron, with a grain of quinine, in a wine-glassful of water, will often stop vomiting and purging that has resisted large doses of laudanum, and of solution of morphia. That so small a dose of this combination should ever prove effectual is singular enough, but I do not think it very wonderful that opium should rather increase than diminish these symptoms, if they are really mechanical effects of congestion, and the results of loss of irritability in the capillary vessels, (not of irritation in the viscera,) for opium will evidently tend to subdue whatever irritability may be left in the nervous system, and thereby give more scope to the anti-vital influence, instead of opposing it. Theoretically, such should be the effects of opium, and practically, I am very sure, that it more frequently tends to keep up the vomiting and purging, and the algide symptoms, than to cure them. If the symptoms proceed from partial paralysis, or loss of irritability of the sympathetic, nothing could be better calculated to augment them than opium, for in at least half the cases in which opium is prescribed in ordinary practice, its sole object is to subdue morbid irritability of the sympathetic system. If, however, our reasoning upon the etiology of cholera has had any foundation at all, it goes to prove that the great object of cure is to maintain the vital sensibilities active, and to husband the power of the heart, and neither to exhaust irritability by undue excitement, nor to lull it into insensibility by opiates, for our hopes all depend on the integrity of these qualities, when the period of capillary relaxation arrives.

With respect to most medicines given in pill, I consider them nearly inert in the congestive stage of cholera, more especially those which are not soluble in water, but require the action of the secreted juices of the stomach for their solution, for we know that such secretion does not then take place. Calomel is fortunately one of this class, and in cholera passes through the bowels almost unchanged, and I am told on good authority may often be found at the bottom of the

bed-pan in the form of a grey powder. With respect to the influence of calomel in this disease, I am fully satisfied that the most mistaken opinions prevail. We have already alluded to the effect of tartar emetic, which is said to be eminently curative, and on the principles of nervous impression, we can well conceive that it will be far from inactive, if it produce its characteristic effect, because that effect is a vital one of great influence on the whole of the sympathetic system, and were we destitute of safer and more appropriate medicines, it might be well worthy of trial. In like manner croton oil has been recommended: it may act like the diarrhœa of cholera, or venesection, in reducing the volume of the blood; but if it produce secretion, which is a vital action of the bowels in opposition to exudation, may operate as a stimulant to the vital energies of the sympathetic, and prove curative. (The danger of inducing syncope by these means is, however, too evident to require comment.) So also may any other medicine or means whatever cure, which produces a powerful impression on the nervous system, provided it do not act by injuriously stimulating the heart's action,—by impairing the force of capillary circulation, or the excitability of the nervous system,—or, in other words, if it be not calculated to produce the very effects which are caused by the exciting cause of the disease. Upon this principle CALOMEL, if it act as a purge, may prove beneficial, but if it affect the constitution, it can only be detrimental This, I think, will become evident, if we consider the action of mercury but for a moment; its chief value is in subduing inflammation, but all our observations tend to shew that the condition, both of the blood and of the capillaries in cholera, is diametrically opposed to that of inflammation. The medicines most useful in cholera and allied diseases,—viz., iron and quinine, are those most opposed to the effects of mercury, and most curative of them. All experience goes to prove that mercury, if an irritant, is at the same time a cause of positive weakness of capillary circulation, with the single exception, and that a doubtful one, of its effect upon the liver. There is no point in medicine on which I feel more entirely convinced, than that the constitutional effects of mercury are invariably injurious in cholera, and tend to produce consecutive fever. Soon after cholera appeared to have ceased, in 1843, I submitted two patients to a course of mercury for chancre at the same time,—one, a groom, died collapsed as soon as the gums became affected, though a very healthy powerful man; the other, the Persian High Treasurer, fell into the same condition, and was only saved by large and quickly-repeated doses of quinine and iron, and went through a severe attack of consecutive fever.

Mr. Parkes mentions, that two syphilitic patients, while under the influence of mercury, were attacked by cholera in his hospital, as proof that mercury is not prophylactic, I might mention several instances to prove it really a predisponent; but so many points of difference will suggest themselves in the condition of one labouring under cholera, from that in which we should be anxious to produce ptyalism, that it is unnecessary to pursue the subject farther.

There now remains I think but one material point in the treatment of cholera, viz., that connected with the use of FRICTIONS and RUBEFACIENTS. Of these, it may be sufficient to say that their efficacy will depend upon the period at which they are applied, which is always difficult to decide, and on the degree of fatigue thereby occasioned to the patient, they partake much of the nature of heat and stimulants; but if applied without disturbing the patient, may perhaps be beneficial, although I have not myself very much confidence in them. Disturbance of the patient is a question of much more importance. In a report of the Commissioners of Public Health, much evidence is adduced by the examination of several medical men practising in London during the former visitation of cholera, as to the ill effects of removing cholera patients to temporary hospitals. There is very obvious reason for desiring to remove them from the locality in which they have actually acquired the disease, because, undoubtedly the cause exists there, and will continue to operate powerfully against the effects of remedial measures, and will also endanger the health of those who are in attendance, and if any of them happen to be attacked, it is sure to give apparent countenance to the popular belief in contagion; but if the disease have been acquired elsewhere than in the dwelling, no object is to be gained by removal unless to a very decidedly more healthful locality, while on the other hand, the evidence is conclusive that danger often attends the practice. In considering the stages of cholera, it was remarked that there is a time when the patient appears rather indifferent than stupid—not asleep—for sleep never occurs in cholera, but as if resigned to fate rather than willing to make the slightest exertion. This condition marks that stage in which the tendency to *cessation of morbid inaction* exists rather than reaction of the powers which circulate the blood, that, namely, in which the influence that causes the disorder is so equally balanced against the resistance of the vital powers, that the slightest disturbance or source of exhaustion will turn the scale, and it is the merest chance whether a stimulant will now rouse the vital powers to throw off the oppression, or by disturbing the circulation then in progress to partial recovery, renew the congestion. It is at this period that the greatest danger of syncope and collapse is incurred by an attempt at removal, and even frictions or anything that tends to disturb the patient may induce syncope and collapse; but sinapisms and blisters that can be applied without disturbance, may prove beneficial.

It is almost needless now to state the practice that I should myself pursue in this disease. If asked what I should do in a case of cholera, I should answer that, that depends very much on the stage in which I found my patient, but in all cases and in all stages I should certainly give a largely-diluted solution of some salt of iron and quinine, with a view to counteract the morbid inactivity of capillary circulation, and repeat it as often as the patient would drink of it till warmth was restored. If called to one of those cases of sudden collapse, with little vomiting and purging, reported to have frequently caused death in eight hours in Scotland,

I should be satisfied that mechanical assistance was required to relieve actual congestion, and if I arrived sufficiently early would open the veins of both arms, trying to induce sneezing and coughing, or almost any powerful vital action, likely to give an impulse to the blood, and cause it to flow. If, however, I arrived too late to bleed, I should not hesitate to conjoin Epsom salts with the mixture, however heterodox such practice may appear, because such cases are generally without purging, and purging is a safer and more direct source of relief than bleeding late in such a case; and I have followed this practice largely with success. I should neither give stimulants nor apply heat, should limit external applications to a blister or tincture of capsicum to the spine, be careful of disturbing my patient unnecessarily, and endeavour thus to carry him over the first twenty hours with life; if his condition was then such as to give little hope of his being able to sustain a fresh attack of congestion, I should risk everything to obtain blood to such an amount that the colour should become florid and its motion free, and should continue the medicine till the secretions became fully re-established—till the hue of health returned to the complexion and the lips and tongue had lost their pallor.

In all cases of consecutive fever my experience points to the use of the same remedies conjoined with salts and diminished quantity of qninine, which in excess, or even if not in very small quantity, tends to produce dryness of the tongue, but which I think necessary, nevertheless, for a time. Perseverance in this treatment long after the secretions are restored, no doubt sometimes tends to produce a red, furred, and bilious tongue, very different from the clean, glazed, and dry red surface, or pale-edged darkly-coated appearance that preceded it, but then the fever has become bilious, and may safely be treated with a smart dose of calomel, or what I find still better, sweating in the wet sheet of the hydropaths. The same treatment is appropriate to the prevailing form of remittent, commonly called low fever unpreceded by cholera or noteable collapse, and unaccompanied with maculæ or typhoid erruption, but characterized by the appearance of the tongue. If the spleen be tender on pressure, a short trial of sulphate of iron with sulphate of magnesia, without, or with not more than half a grain of quinine to each dose, with occasional application of leeches to the epigastrium, (in the forenoon,) will, I think, show that there is something in the treatment recommended, if nothing in the theory. *Post-mortem* examination in this type of fever constantly exhibits more or less softening of the spleen, a characteristic of tropical remittents, and in my opinion a positive indication for the exhibition of iron.

I must now conclude, but I confess I leave the subject with much reluctance, for there are many points of much practical importance left untouched; among others, the influence of the epidemic constitution while cholera prevails upon other diseases apparently unconnected with it, is full of interest.

Of these I cannot refrain from mentioning one example before concluding. While cholera prevailed I had two patients with pannus oculi, in which I had tried every possible local application in vain; one of them, however, had on one occasion a slight shivering fit when he visited me, and I gave him a mixture of quinine and iron, the pannus immediately began to diminish, and I tried the same medicine on the other, omitting local applications, and in both a cure was effected in the course of ten days. Similar effects were observed in a great variety of other diseases. I am very well aware, that in this laudation of a particular combination of drugs, I have subjected myself to the charge of empiricism, and in a certain degree I must acknowledge the charge to be just, for nothing could be more purely empirical than the grounds upon which I was first induced to make trial of it, whatever my subsequent endeavours to explain its operation; but my object now has been only to recommend the combination of iron with quinine to your consideration, as a means well fitted to attain the end in view,—viz., to promote the oxygenation of the blood, to fortify capillary action and nervous irritability, to confirm the tendency to remission (whether apparent or too obscure to be noteable but presumable,) and to prevent periodical return of venous congestion. I have endeavoured to shew that these are the primary objects requiring attention; relief of congestion by mechanical means the secondary one.

If I have over-rated the effect of the medicines recommended, I must be allowed to say that I have not been induced to do so by theory alone, for that which I have offered to you is solely the result of reflection after I had used it in many thousand cases effectually, but purely empirically. While the epidemic prevailed in Tehran, my court-yard was daily crowded with hundreds of poor wretches, praying for the love of God for a supply of the bitter water, or water of life as they called it. It was served out to them in pint-and-half mixtures of water, containing twelve grains ef quinine, nine of sulphate of iron, and thirty drops of dilute sulphuric acid, with directions to take a coffee-cupful for a dose; these orders, however, were not always attended to, and in some of the most remarkably rapid cures I witnessed, the whole was swallowed at a draught. One of these I particularly remember.

In visiting one of the princesses, the wife of the Chief Astrologer, I observed a wretched object, who had dragged himself to the tank in the outer court of the house; with difficulty I recognized him as the tutor of the family. He had been vomiting and purging, and agonized by cramps, and his thirst had impelled him to the position in which I found him. I immediately sent him a quart bottle of the mixture described, and I was never so much surprised as to see him in the afternoon at my house with his bottle, whither he had walked nearly a mile, to beg a fresh supply, having swallowed the whole at once, and felt immediately revived. I had previously known him as, both from religious prejudice and as an epicurean, an abhorrer of medicine; and this certainly was not nectar. Villainous though the compound may seem, it appears to be peculiarly grateful to the patient, by appeasing the thirst and sense of heat in

the stomach, which even ice fails to allay, and I have seldom seen it vomited after the first dose or two. I have met with one or two instances in which it was found impossible to obtain blood from the veins, but where, shortly after a few doses of the medicine had been taken, bleeding was practised with success.

In the cases of simple diarrhœa without tenesmus now prevailing, I find the most immediate effect produced by a grain or two of quinine given with half a drachm of the muriated tincture of iron, in a wine glassful of water. With respect to the cramps and spasms, I have been in the habit of looking upon them as mere symptoms, only to be obviated by removing the cause; it would, however, appear from the observation of others, that, apart from the more fatal symptoms of suppressed arterial circulation evinced in convulsions; the cramps in the legs, &c., are closely connected with the contracted condition of the colon, and I should therefore feel inclined to try the effect of assafœtida injections.

I have now, gentlemen, only to thank you for the attention with which you have listened to my remarks. The treatment which I chanced to adopt on purely empirical grounds appeared to me more than usually successful, and I was led to enquire whether there was anything in the nature of the disease, or the remedies, that was explicable on known and acknowledged principles of physiology and therapeutics; the result was, that there existed a deficiency of facts by which to determine the question, and, till these were settled, it was impossible that all should agree on the treatment or deductions, at the same time it was evident that there were facts which, if generally admitted, would necessitate universal concurrence in a broad principle of treatment, to the exclusion of a vast amount of erratic practice, that might be termed a blind groping for facts on which to reason.

In my endeavour to ascertain what were the established facts, it appeared that beyond a rehearsal of symptoms there was not one universally admitted, save the constant existence of venous congestion,—contagion, the effect on the blood, the cause of death, the influence of particular treatment, were all subjects of hot contention, and the medical profession was divided into as many parties, and more, than there were sections in the materia medica. Under such circumstances it appeared that the weight of any single evidence could not possibly turn the scale of opinion, and that the only chance of arriving at a useful conclusion was to examine the disease in all its forms, as they relate to its cause, its course, its terminations, and its connection with other diseases. The result of this I have endeavoured to lay before you, in the reduction of the essential facts to six, not one of which is generally admitted, but if they be proved to be facts, the deductions from them are too evident to require comment. These which have previously been stated at length are shortly as follow:—

1st. That cholera is the effect of impression on the sympathetic system,—that its cause does not primarily affect the blood, is incapable of reproduction in the body, and, therefore, incommunicable.

2nd. That its effects begin by impaired vitality and disordered function of the capillary circulation.

3rd. That congestion of the thoracic and abdominal veins is the consequence of the above condition, and the cause of other symptoms.

4th. That exudation of the watery particles of the blood, whether through the mucous, or into the serous tissues, constitutes the natural mode of relief to this congestion.

5th. That cholera goes through certain diurnal stages, of which capillary disturbance is the first, venous congestion the second, more or less intermission or cessation of capillary disturbance the third.

6th. That the natural tendency of cholera is to go through these successive changes for three days, and then cease, or to run into consecutive or remittent congestive fever.

It appears to me that if these are facts (the establishment of which will depend on the observation and reading of every practical man,) a principle of treatment is inevitably established along with them, because they are facts on which the whole pathology of the disease may rest, and the whole course of treatment depend. If they prove otherwise, I have wasted your time and my own, in a feeble attempt to recommend a combination of quinine with iron, as only one of the numerous medicines said to be beneficial in cholera, but the action of which will then be totally inexplicable; and I shall owe you all much apology for inviting you to listen to the arguments by which I have attempted to substantiate as facts, what another process of reasoning may, perhaps, demonstrate as fallacies.

[At the conclusion of the lecture the thanks of the meeting were voted to Dr. Bell, on the motion of Dr. Bardsley, senior, seconded by Dr. Lyon.—Ed.]

BRONCHITIS AND DEATH

IN CONSEQUENCE OF TWO TEETH BEING DRIVEN DOWN THE LARYNX.

By S. B. Denton, M.D., Hornsea.

I was called to a Miss Fawcit, from Sheffield, September 14th, 1848, who had been ill three days. The history she gave me was this:—Feeling tolerably well she went to the sea-side; while there she had an accidental fall, and found on getting-up that two front teeth had disappeared, (they were false, tied together in a gold socket,) they were not to be found about her person, or amongst the shingle. A cough almost immediately came on, which had continued to harrass her much up to the time I saw her.

I found the poor sufferer labouring under an acute attack of bronchitis, and although her attenuated frame could ill spare one drop of blood, I durst not omit the application of a few leeches, with two or three emetic draughts of Antimonii Potassæ Tartras.

It was rather late at night when I saw her, and contrary to my request, she left at eight o'clock the next morning for her home, at Sheffield, I did not, therefore, see her again, but was told that she was much relieved.

I wrote to Dr. Corden Thompson, of Sheffield, (Miss Fawcit's physician,) giving him the above account, and at the same time stating that I had no doubt in my own mind that the teeth went down the windpipe, which was the *mechanical* cause of the inflammation and suffering, and I feared would, (if it had not already done so,) terminate in death, and on a *post-mortem* being obtained, doubted not but the teeth would be found in some of the air-passages. I had not an opportunity of exploring the chest by auscultation, and therefore could not decide upon the exact spot where the teeth were lodged.

Dr. Thompson very kindly sent me the dissection report of this interesting case, which is as follows :— "From the previous history of the case, and the existing symptoms, I was led to conclude that the teeth lay in the right bronchus, near its issue from the trachea. The patient gradually sank. I do not dwell on the symptoms particularly; they continued of the same character as you witnessed; there were also evidences of hepatic disease, and she had a heart affection, of some standing. The teeth were found precisely where it was anticipated: they lay firmly impacted near the mouth of the right bronchus. I need hardly say there were marks of severe inflammation in the tube; some also in the left bronchus, but not extending in the trachea to the larynx; the left lung pretty natural in appearance; the pleura costalis recently inflamed, but without effusion; on the right side the lower portion of the lung was somewhat consolidated; there was inflammation, too, both of the pleura pulmonalis and costalis, with slight adhesions posteriorly, and a little effusion; the upper portion of the lung had a pretty natural aspect without, but did not collapse; it appeared to have kept distended by the impeded egress of the air having, no doubt, been fully dilated by the inspiratory act which forcibly drew in the teeth. The parietes of the left ventricle of the heart were thick and firm; the mitral valve was also much thickened and indurated. The liver at its fine edge was verging to scirrhus, with traces of recent peritonitis of its surface. The other viscera were sound. The head was not allowed to be opened."

I believe Mr. Wood attended the patient with Dr. Thompson, and took the same pathological view of the case.

POISONING BY THE BERRIES OF THE TAXUS BACCATA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

There are very few cases recorded of poisoning by the berries of the Taxus baccata; indeed, many persons disbelieve in its poisonous nature altogether. Gray, in his treatise on "Pharmacology," says, "the berries have been thought to be poisonous, but they may be eaten." I believe they are not mentioned by Dr. Christison, in his valuable work on "Poisons." Drs. Copland, Guy, and Taylor, in their respective works, bear testimony to the extremely poisonous nature of the Taxus baccata. Mr. Lloyd's experiments and case, recorded in the last Journal, afford additional proof of the poisonous nature of the tree and its fruit; like him, during many years practice, I have only met with one case, which I subjoin for insertion, if you deem it worthy, in the Journal.

I am, Sir, yours faithfully,

JAMES TAYLOR, M.D.

Castle Cary, Dec. 12, 1848.

Sunday, October 28th, 1838. Mary Baker, a fine healthy child, between five and six years of age, ate freely of yew berries just before going into church. About an hour after, during divine service, she fell from her seat and was instantly removed, in an insensible state, to her home. I saw her immediately; the surface of the body was cold; the countenance pale; breathing laborious and frequent; pupils very dilated; pulse feeble; convulsions, and vomiting. Having carefully examined the head, and finding it was not injured by the fall, I gave an emetic, and from what was ejected, it was evident she had eaten a considerable quantity of the berries; not the mucous part only, but the seeds, wherein I believe is the most active principle of the berry, for the mucous or fleshy part of the berry has been frequently eaten with impunity. As soon as it appeared the stomach had been freed of its contents, a purgative was given, and had the desired effect, but the child never rallied from the first. She continued in a comatose state, and died in *four hours* after eating the berries. An inquest was held, but no *post-mortem* examination allowed. I stated, in my evidence, I considered yew berries poisonous, and that the child's death had been occasioned by them, but I remember several on the jury were very sceptical on the point.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, DECEMBER 27, 1848.

As the present number forms the concluding one of the volume for the year, and a considerable portion of its columns is necessarily occupied with the Index, we feel ourselves obliged to confine our observations within a very limited compass. Perhaps we cannot do better on this occasion than congratulate the members of the Association on the value and importance of the many original communications which have been published during the twelve months now approaching to a termination.

We have no wish to take merit to ourselves for this manifest improvement, but we cannot but consider it as a mark of confidence and approbation on the part of the members, and a testimony of the favour with which they are disposed to regard the Journal. At the same time we have the gratification of knowing, from many quarters, that while the communications

of our valued correspondents are extensively appreciated, the general tone of the Journal also meets with approval.

It would be invidious to particularize, but we cannot but refer to the valuable facts elicited by the "Inquiry into the Treatment of Burns and Scalds," carried on under the sanction of the Council, by Mr. Crompton, of Manchester, as a proof of what the Association has in its power to effect. We anticipate that when these facts shall have been classified and arranged, and the legitimate conclusions deduced from them, a most valuable report will be the result. The "Inquiry into the Medicinal action of Arsenic," simultaneously carried on by Mr. Hunt, of Herne Bay, will, we expect, be also productive of important information, but as the facts of that inquiry have not yet appeared in the pages of the Journal, it is unnecessary for us to allude to it farther in this place.

We may also, perhaps, be permitted to distinguish the elaborate series of papers "On Turning, as an Alternative for Craniotomy and the Long Forceps," by Professor Simpson; and the valuable "Notes on the Opinions and Practice of the late John Pearson," by Dr. Oke. We have referred especially to these papers on account of their completeness and extent, as well as their general importance; but we must add, that there are many other papers not inferior in value and importance, which in our opinion render the volume now concluded fully equal to any of its predecessors.

We have to apologize to some of our correspondents for a delay, unavoidable under the circumstances, which has taken place in the publication of their communications. We shall endeavour to make arrangements for the early insertion of these in the new volume. In conclusion, we trust we may expect a continuance of the support hitherto received, and that the Journal of the Provincial Association will be recognized, not only as the organ of the Members of the Association, but also of provincial practitioners in general.

Reviews.

A Treatise on the Diseases of the Heart and Great Vessels, and on the Affections which may be mistaken for them; &c. By J. Hope, M.D., F.R.S., &c., &c. Fourth Edition. London. 1849. 8vo, pp. 611.

This is a new edition of the late Dr. Hope's well-known "Treatise," reduced in size, and consequently in price, by the adoption of a smaller type, and the omission of the plates, and of some controversial matter, now of little importance. To those who are desirous of possessing this truly standard work, and have not been able to avail themselves of the last edition as published by the author, we would strongly recommend the present one. Mr. Churchill, in making these arrangements, while he has judiciously reduced the price, and brought the work more immediately within the means of all, has at the same time had due regard to the eyes of the reader, the type being still sufficiently large to be agreeable.

Medical Jurisprudence. By Alfred S. Taylor, F.R.S., Licentiate of the Royal College of Physicians, &c., &c. Third Edition. London. 1849. Fcp. 8vo, pp. 859.

It is merely necessary to announce the appearance of another edition of Dr. Taylor's well-known and equally well-appreciated work. We ought, however, to observe, that this edition is not merely a reprint, that it contains nearly more than one-sixth part of additional matter, on various subjects, and that a considerable portion of it has been entirely re-written. We need scarcely observe, that what has been added is in the same style of excellence as distinguishes the preceding editions, and has rendered them of such high standard authority.

Lectures on the Parts concerned in the Operations on the Globe, and on the Structure of the Retina. Delivered at the Royal London Ophthalmic Hospital, Moorfields, June, 1847. By William Bowman, F.R.S., Fellow of the Royal College of Surgeons of England. 8vo, pp. 45.

These Lectures, delivered by the author at the Royal London Ophthalmic Hospital, have been re-published in a collected form from the *Medical Gazette*, in which periodical they originally appeared. They fully maintain the high reputation which Mr. Bowman has already attained as a physiological writer, and are calculated to convey to those who peruse them, a minute and intricate knowledge of the anatomy and physiology of the part of which they treat—a knowledge which is the only true foundation of the correct treatment of ophthalmic, as of all other diseases.

We understand that Mr. Bowman is prosecuting his researches into the morbid anatomy of the eye, and is anxious for as many opportunities as possible of inspecting rare or remarkable specimens. In an enquiry of this sort, where great difficulty is usually met with in obtaining from the body after death the parts which have been the seat of the morbid change,

it is desirable that every assistance should be rendered by the profession, and we would beg to recommend any of our readers who may have it in their power, to contribute to the furtherance of this enquiry, by transmitting any specimens of rare cases they may chance to meet with, to the author of these valuable Lectures.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

September 7th, 1848.

JOSEPH WICKENDEN, Esq., in the Chair.

RECTUM TERMINATING IN A CUL-DE-SAC.

Mr. Wickenden gave the following history of the case:—A female child, large, well nourished, and apparently well formed, born August 23rd, 1848, 10, a.m. Within three hours after birth the infant took the breast voraciously, when she fell asleep, and slept many hours. When she awoke she refused the nipple, and never sucked again.

On the following day the nurse reported that the child had often made water, but had had no motion. A dose of castor-oil was then given; this induced vomiting; oil, mucus, and a yellow sticky matter, were thrown up. The child now strained violently to stool. On carefully examining the anus, which was unusually open, and of triangular shape, it was found of a red aspect, somewhat like a sprout of fungoid growth. A cylinder of soap could be introduced about half a barley-corn in length, a blunt probe not farther, and the little finger passed as far. The abdomen had become tense. Thirty-five hours after birth a director was introduced as far as possible, and with a phymosis-knife an incision was made in the direction of the usual track of the rectum, the point and concave of the bistoury being directed upwards and backwards, to avoid, if possible, the vagina. The instrument was seemingly plunged into an elastic swelling; a few drops of blood only followed. Into the opening thus made, the canula of a trocar was introduced; this, at about an inch and a half, pressed against the elastic swelling before felt. Through the canula a trocar was thrust; this was not, however, followed by meconium, but by a few drops of blood, and a drop only appeared at the orifice of the vagina, which was unusually large. A poultice was applied, and the child passed a quiet night, though she vomited occasionally. On the third day the child seemed little altered in appearance. Seventeen hours after the operation hæmorrhage came on from the vagina, and occurred at intervals for many hours. At ten o'clock, p.m., the infant was tranquil, and died before midnight.

Examination twenty-three hours after death.—External appearances: A fine well-nourished child; abdomen much distended; funis flattened, dried and transparent; a small clot of blood in the orifice of the vagina; the anus apparently patent. Opening the cavity of the abdomen, the first incision disclosed much fat and very distended intestine, the colon especially; there was no air in the cavity of the abdomen. The symphysis pubis was divided, and the bladder, uterus, and vagina removed, the posterior wall of the vagina being much infiltrated with blood, having been necessarily wounded in the operation. The rectum was entirely wanting. The colon terminated in the median line of the body in a cul-de-sac; it was much distended with meconium, which was slightly thinner, and not quite so dark coloured as usual; the appendix vermiformis cæci was unusually long. The uterus bi-angular rather than pyriform.

PISTOL-SHOT WOUND.

Mr. Bindley presented a portion of the skull pierced by a pistol ball.

This preparation is a part of the left parietal bone of Mr. Davenport, shot (as most of you may probably remember,) some ten years ago, on Snow Hill, in this town, by a man named Devey, who was executed at Warwick, for the murder.

The ball penetrated the parietal bone a little above its anterior inferior angle, passed in an oblique direction through the brain above the corpus callosum, lacerating the lower border of the falx cerebri, and struck the parietal bone on the opposite side, anterior to the mastoid process of the temporal bone. At this point the scalp was raised and puffy, and on coming down to the skull, a portion of detached bone was found knocked out by the bullet; the bullet, which was cut into two parts, was lying within the cranium near to the opening, where were also a number of small osseous fragments; some fragments were also found along the course the ball had taken. The preparation shows the action of the ball on the tables of the skull. The aperture is ovoid in figure, and in the dense tough outer table smaller, being three quarters by half an inch in its dimensions, while in the inner and brittle table it measures one inch by three quarters. The reverse of this, however, is observed in the detached portion of bone struck from within.

LARGE BILIARY CONCRETION.

Mr. W. H. Partridge gave the following particulars:—An old gentleman, aged 78, tall and thin, and of good general health, was attacked by jaundice and frequent vomiting, and had severe fixed pain in the region of the gall-bladder. The attack lasted three weeks, after which some amendment took place, and ultimately bile was passed by the bowels. Two months afterwards obstinate and insuperable constipation came on, accompanied by vomiting of stercoraceous matter, followed in a few days by exhaustion and death.

On making a *post-mortem* examination, all the parts in the neighbourhood of the gall-bladder, the pyloric end of the stomach, duodenum, pancreas, and colon, were closely and firmly adherent to each other, and to the concave surface of the liver. No trace of a gall-bladder could be discovered. A large biliary concretion was found in the lower part of the ileum, a little above the cæcal valve, and though but loosely embraced by the gut, was manifestly sufficient to account for the fatal obstruction. In figure it was somewhat pyriform, exactly resembling the gall-bladder, having also a curved tapering process, corresponding to the cystic duct; in length it measured three and a half inches; in the circumference of its large portion, four inches. The texture was light; weight, seven drachms and one scruple.

ROYAL SOCIETY.

THE BAKERIAN LECTURE: MR. FARADAY'S NEW DISCOVERY.

It will be remembered that about two years ago, Mr. Faraday discovered the diamagnetic property of all non-magnetic bodies. It was believed previously, that iron, nickel, and cobalt, were the only bodies in nature acted on by magnetism. Mr. Faraday then shewed that all bodies were influenced by magnetism, but in a different manner to iron. Whereas, iron placed itself between the two poles of a horse-shoe magnet, and in the axis of the current, all non-magnetic bodies placed themselves *across* the magnetic current, and midway between the two poles. He called these diamagnetics.

In the Bakerian Lecture, read at the Royal Society, on the 7th of December, (see *Athenæum*, Dec. 16,) Mr. Faraday has made known the discovery of a new fact. He finds that bismuth when in regular crystals is *magnetic*. A crystal of bismuth, when suspended between the poles of an electro-magnet, places itself in the axis of the magnetic force as a magnetic needle would do. If the crystals are broken up and fused, then the bismuth places itself *across* the axis of the magnetic force. The new position depends, therefore, on the state of crystallization, and is in a line perpendicular to the most perfect of the four cleavage planes of the crystal. This line, in which the crystal is as magnetic as iron is called the magne-crystalline axis. Although the crystal of bismuth is magnetic in one direction, it is still dia-magnetic so far as to take up a position between the two poles. Mr. Faraday, in his conclusion, alludes to the progress recently made in the knowledge of molecular forces, encouraging him to pursue his labours "in the hope of bringing magnetism into a bond of union with gravity itself,"

As physiologists, we cannot but look at this extension of our knowledge of these forces with sanguine anticipations. To know that all organic matter is influenced by magnetism, is a very important physiological fact, taken in connection with modern discoveries of the existence of electrical currents in the body, and with the co-existence of the magnetic and the electric forces. Nor can we forget that Faraday has been carrying on his quiet labours so fruitful in new discovery, at a period when Continental philosophers have been embroiled in revolutions; and that science has pursued her steady and useful course in this island, whilst she has been distracted, and for the time obscured, in France, Germany, and Italy.

NOTES FROM A PRACTITIONER'S DAY BOOK.*

THE MODE IN WHICH THE NITRATE OF SILVER CHECKS THE EXTENSION OF ERYSIPELAS.

When an irritant poison is introduced into a living part, the actions of the protective function are excited to prevent the extension of its operation. All the phenomena which are usually denominated "inflammation," immediately commence; fibrin is effused, and a barrier is quickly formed to circumscribe the poison, and to limit its mischief. These effects are noticed in the small lump which is raised by a gnat-bite, and the larger swelling which is produced by the sting of a wasp or bee. If, however, the operation of the poison is more powerful, the actions of "inflammation," though excited, are not sufficient to check its progress. The poison, as it were, runs a race with the protective function, and constantly getting before it, allows the inflammation no time to establish the protective barrier. This is the case in the wound inflicted by the poisoned tooth of the serpent; we also witness a similar instance in the extension of erysipelas. In that form of this affection in which the inflammation is confined to the cutaneous surface, and gradually extends from one part to another, the actions of the poison are in advance of the protective function. If, according to Mr. Higginbottom's plan, we apply the nitrate of silver to a part of the skin where the actions of the poison have not yet reached, the erysipelas, when it arrives at this place, ceases to extend. The irritation of the caustic has established a barrier of effused fibrin, which arrests the progress of the poison.

CASE OF HEREDITARY SYPHILIS.

A little, puny, emaciated infant, was brought into my surgery by an old woman, who had come on the part of the mother. The child was about three weeks of age. Its lips were covered with incrustations, which cracked and bled every time that it cried; the whole body, but more especially the skin round the anus and nates, was spotted with a copper-coloured papular eruption; it constantly snuffled, and its nostrils were obstructed with sanio-purulent incrustations. The mother had an abundant supply of milk, which was taken eagerly by the infant; nevertheless, it had never thrived since birth, but had always been the miserable object it now appeared, and even daily became worse. Finding that the old woman was not likely to make a malicious use of the information, I freely told her what was the matter. A few days after, a very smartly dressed and pretty young woman came bouncing into my room, and said that I had been injuring her character. Ascertaining that she was the mother of this infant, I told her that she would never bear healthy children, that more probably she would bear no more alive, and that more probably still, all her conceptions would end in miscarriage. The woman's tone was immediately changed; she had had several miscarriages she said; one child was born dead and black, and the only living offspring was the miserable object I had seen. She now confessed that a few weeks after marriage she had suffered from sores, as her husband had also done. When she mentioned his name, I recognized an old patient, who had long suffered from chronic rheumatism; with this exception, however, neither parent seemed out of health, and on examination of both, I could find no induration in the seat of the former chancres. I placed both upon a long course of mercury, intending to keep the gums slightly tender all the while. To the husband I gave, in addition, the iodide of potassium, which soon removed his rheumatic

* Continued from page 641.

pains. I cannot state the result of this treatment, for after two months I lost sight of my patient. For the infant I prescribed two grains of grey powder, and ten of the compound chalk powder, to be taken twice daily, but so wretched was its condition at the time, that I anticipated nothing but a fatal result. In the course of a few days, however, some improvement began to be visible, for the labial incrustations were separating at the edges, and there was now no longer any bleeding. This improvement continued progressing; in the course of three weeks there were no remains of the eruption, and at the end of two months the infant, though small, seemed well.

ACTION AGAINST A RAILWAY COMPANY FOR PROFESSIONAL SERVICES.

SANDS COX *v.* THE MIDLAND RAILWAY COMPANY.

In the Court of Exchequer this day, (Dec. 9, 1848,) the case of *Sands Cox* v. *The Midland Railway Company* came on for argument. This was an action of assumpsit brought to recover £27, the amount of fees for an operation and attendance performed and rendered by the plaintiff, an eminent surgeon at Birmingham, at a place called Whitacre, on the Midland Railway line, under the following circumstances:—It appeared that an accident had occurred at the station to a man named Higgins, in attempting to get into the train while it was in motion. On being taken up he was removed by the guard to a public-house near the station, where the station-master directed every care to be taken of him, and sent for Mr. Davis, a medical man living at Coleshill, who had been employed and paid by the Company on similar occasions before. On the arrival of that gentleman, the patient was discovered to be in a most critical condition, and Mr. Davis hesitated to amputate the injured leg. He then spoke to the station-master, suggesting the propriety of telegraphing to Birmingham for Mr. Hodgson or Mr. Sands Cox. Owing to some impediment the signals could not be conveyed, and the mail train was stopped, and Mr. Davis went by it to Birmingham to consult Mr. Needham, the superintendent of the Company, to whom the station-master referred him. That gentleman expressed his readiness to do everything in his power to alleviate the sufferings of Higgins, and Mr. Davis went with his consent to Mr. Sands Cox, who proceeded to the station, where a carriage was attached by Mr. Needham's directions to the luggage train to convey him and Mr. Davis to Whitacre. On arriving there Mr. Sands Cox took off the limb, and then returned to Birmingham, whence he paid some other visits to the patient, who ultimately recovered, and gave his evidence in Court on the trial of the cause. On his recovery he brought an action against the Company, who settled it by paying him £150. After this Mr. Sands Cox, Mr. Davis, and Mr. Silk, the landlord of the inn, brought their actions against the Company to recover the amount of their respective demands for services rendered to Higgins under the above circumstances, At the trial, which took place before Mr. Justice Maule, at Warwick, a verdict passed for the plaintiff in the present action, for £27, with leave to enter a nonsuit, if the Court should think there was no evidence to go to a Jury of any authority from the Company to their officers to bind them by any such contract, *Mr. Justice Maule observing, in the course of the discussion,* that "*if the defendants were in earnest in their defence, they had much better put up a notice at their stations, that if any accident should happen to the passengers, they would not give any medical attendance; and that if any of their officers employed a surgeon, they would not pay for the doctor.*" After this intimation the defendants' counsel did not "go to the Jury," but consented to a verdict in all three cases, relying on this point of law in the Court above. Rules having been subsequently obtained in each case, the same now came on for argument, and Mr. Whitehurst and Mr. Hayes showed cause. The question was, first, whether the defendants, being a corporation, could be bound by any parole contract under the circumstances; and 2ndly, whether, if a contract under seal was not required in such a case, there was any evidence of any implied authority to their officers to enter into any such contract on their behalf. As to the first point it was submitted that it would be impossible to conduct a railway if such contracts could not be entered into by parole. An accident required prompt attention, and before the corporation seal could be attached to any written contract of hire for labourers to clear the line, or for any other purpose, the passengers might all die. This was too great an absurdity to be sanctioned for a moment. The contract to carry this passenger was not under seal, and the liability here arising out of the breach of that contract was one which attached without any formal instrument under seal. It had been held that Corporations could enter into certain contracts of a minor character, and the principle must be carried out according to the altered state of society. Then, as to the second point, there was enough to show that Mr. Needham had authority from the Railway to employ Mr. Sands Cox, and to bind the Company. Their negligence had occasioned the accident—at least it was not questioned at the trial; and it was for their advantage that medical aid should be obtained, and there was evidence that on a former occasion they had paid the bill of Mr. Davis, who had been employed by the station-master at Whitacre.—Mr. Macaulay, with whom was Mr Humfrey, for the defendants, contended that the Company could not be held liable under the circumstances, as the employment of Mr. Sands Cox was not an act within the scope of Mr. Needham's authority as their servant, reference being had to the nature of the business carried on by the Company as carriers on a railway.—At the conclusion of the arguments, Mr. Baron Parke said the Court would consider. The case was of great importance, for it would not be confined in its operation to railway companies, but would extend to the servants of private individuals.—Jndgment deferred.—*Daily News*

PROFESSOR OWEN AND THE SANITARY COMMISSION: REPLY TO MR. POYSER'S LETTER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In your last Journal Mr. Poyser has, in a short letter, thought proper to notice an article of mine, published in the Journal of November 15th. He

labours under the hallucination that I have assailed the reputation of Professor Owen,—deludes himself with the idea that I think the Government unwise in selecting such a man as Dr. Southwood Smith as a Sanitary Commissioner, and a member of the Board of Health,—avers that I have made a gratuitous charge of venality against the medical profession, and very charitably attributes to me, as the motive by which I have been actuated, "a prurient desire to attack the reputations of others." Never, in so short an epistle, were so many "men of straw" raised up. The charge of scurrility brought by this gentleman against the other weekly Journals I do not feel called upon to notice, but the doubtful compliment to yourself, in the wish expressed by him "to deprecate the insertion of these attacks," contains a rebuke altogether uncalled for. Allow me to examine briefly his imaginative accusations *seriatim*.

First, then, as to the charge of assailing the European reputation of Mr. Owen. The error of attributing to Mr. Owen any of the responsibility of the Irish Potato Commission I have explained very candidly in my letter in your last Journal; such an inadvertency must occasionally escape the most diligent editorial scrutiny; I suppose, however, one may venture to criticize very good humouredly the "moot" points of a public document like the Sanitary Commissioners' Report, without being actuated by any "prurient desire to attack the reputations of others." Any one who has read through the two volumes will, I think, be at a loss to find any connection between "pure surgery" and this Commission, and would be equally puzzled to discover how the most profound anatomy, human or comparative, living or fossil, could have afforded the slightest collateral light on the subjects therein discussed. Had Sir John Herschel been called away from the stars, or Lord Rosse from his telescope, to assist Mr. Chadwick and Dr. Smith, I imagine the line of enquiry would have been equally "*ultra crepidam*." Would a candid question of the infallibility of such a misplaced authority be deemed assailing their reputations? The medical doctrines of these astronomers, though their reputations may be European, would, I think, be fair matter of free enquiry; and without the slightest disparagement of their "originality and comprehensiveness of mind," I think we might quote to them the lines of the poet—

> "One science only will one genius fit,
> So vast is art—so narrow human wit."

With respect to Dr. Southwood Smith, so far am I from thinking the Government unwise in such a selection, that I really consider his benevolent exertions in the sanitary question pointed him out as a very fit person for the Sanitary Commission, as well as the Board of Health. The appointment of such a man was a very judicious one. I must, however, at the same time, be allowed in this free country, to question some of his medical doctrines, for we have no Pope in physic. Dr. Davies, in his able "Address on Fever," lately published in our "Transactions," Vol. xvi., Part I., has been equally free in his strictures on some of Dr. Smith's published medical speculations. I do not think it would be any proof of "correctness or good taste," to call him the assailant of Dr. Smith, or to accuse him of a "prurient desire to attack the reputations of others." Dr. Davies has, I believe, pretty clearly proved the fallacy of Dr. Smith's doctrine of the non-contagious nature of typhus fever. I had not read this able address when I wrote my article, but I am happy to fortify my own position by such a valuable and judicious document. Although, then, I may approve of the selection of Dr. Southwood Smith, as an individual member of a Sanitary Commission or a Board of Health, I am not singular in my opinion that a *larger number of eminent professional men* should have been associated with him in such a position, and that the directions of this Board of Health would have had greater weight with the profession, had the sanction of other names been obtained by the Government. It seems that the Colleges of Physicians, both of London and Edinburgh, have taken somewhat similar views, and have, in fact, published directions in some points diametrically opposed to those of the Board of Health. Will Mr. Poyser call this, too, "a prurient desire to attack the reputations of others?"

And now for "the gratuitous charge of venality against the medical profession," which Mr. Poyser says I have been guilty of, because I stated in my article a fact very generally known, and upon which, no doubt, Dr. Bowring could give some information, that medical talent has been employed to write down the quarantine laws, and to upset the doctrines of contagion. The Doctor may have started for Canton, however, and I must, therefore, supply an extract from the "Parliamentary Review" of so early a date as 1825.

"The attention of the medical world," says the Editor, "and of the public at large, has been lately drawn to a renewed attempt to overthrow the received doctrine of contagion, as it applies to the plague, typhus fever, and scarlatina. This opinion seems to have taken its rise in America during the discussions on the subject of yellow fever, more particularly those respecting its contagious nature. Dr. Bayley, of New York, in his account of the yellow fever prevalent in that city, in 1795, maintained that it was not contagious, and extended the same theory to other epidemics. The same doctrine was afterwards adopted and illustrated by Dr. Millar and other American physicians. In this country its chief advocates have been Dr. Adams and Dr. Maclean."

Dr. Townshend, one of the most eminent authorities among American physicians, whose experience of yellow fever in various countries and climates, was of the most extensive character, writes on this subject: "The true characteristics of the pestilential yellow fever have been entirely lost sight of to give place to the more congenial and crude speculations and misrepresentations of empirical adventurers, many of whom, with mercenary motives, (designed to flatter the authorities of different governments, with the delusive hope that commerce might be disburthened of every such restriction as a relic of barbarism,) have not hesitated to assert and disseminate on the subject of yellow fever, a tissue of heresies and errors." I beg to hand over Dr. Townshend to the tender mercies of Mr. Poyser, as an aider and abettor of this "charge of venality."

A celebrated barrister, I believe, attempted to prove that a few apple-pips contained prussic acid enough to account for the quantity found in the stomach of the victim of the murderer Tawell. I do not imagine such

a statement would be construed by any *fair reasoner* into a charge of venality against the legal profession; and although some medical men were actually employed by Madame Lafarge to disprove the fact of arsenical poisoning, attested by Orfila, I do not believe such a perversion of medical talent would be deemed a charge against the whole medical faculty of Paris. The effort to turn the force of my arguments into a "gratuitous charge of venality" is clumsy and unfair in the extreme. The tone and spirit of the article in question is in clear contradiction to such a distorted assumption. But "error," says Curran, "is in its nature flippant and compendious—it hops with airy and fastidious levity over proofs and arguments, and perches upon assertions which it calls conclusions."

I will, now, however, leave Mr. Poyser, having touched his perversions of my humble criticisms merely in self defence, hoping, with your permission, in a future paper to recur to the subject of the contagion of pestilential cholera—a doctrine not quite so extinct as your Wirksworth correspondent imagines.

I am, Sir,

Your obedient Servant,

EDWARD OKE SPOONER.

Blandford, Dec. 16, 1848.

Medical Intelligence.

TESTIMONIAL TO DR. COOKWORTHY.

A testimonial to the services of Dr. Cookworthy, of Plymouth, as Physician to the Plymouth Public Dispensary, was presented on Tuesday, December the 14th. It consisted of a portrait of Dr. Cookworthy, presented by a deputation of the Governors to the Dispensary, to commemorate the fiftieth year of the Institution, and a silver tea-service, presented to Dr. Cookworthy himself, as a token of the regard of the subscribers to the Institution, for his long services. The Mayor of Plymouth was in the chair, and the proceedings of the meeting were of a highly gratifying character.

APPOINTMENTS.

Edward Cock, Esq., Surgeon, to Guy's Hospital, has been appointed Consulting Surgeon to the Deaf and Dumb Asylum, in the room of Mr. Callaway, deceased.

Dr. Fergus, House-Surgeon to the Stafford Infirmary, has been elected Resident Medical Officer at Marlborough College, Wilts.

Toogood Downing, M.D., has been appointed one of the Physicians to the Blenheim-Street Infirmary and Free Dispensary.

UNIVERSITY OF CAMBRIDGE.

On Wednesday, December the 6th, the degree of Doctor of Medicine was conferred on John Abercrombie, Caius College, and that of Bachelor of Medicine on Thomas Denne Hilton, Caius College.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates Thursday, December 7th, 1848:—Warren Fincham; S. Wallace, Carshalton; Robert Woodman, Weymouth; Walter Robert Crouch, Bruton; Matthew Gosling, Liverpool.

On Thursday, December 14th:—Joseph Stewart Burton; Frederick Dicker Fletcher, Canterbury; Thos. Ward Boswood; Joseph Harvey, Milford, Derbyshire; Henry Sanders Grant, Northampton.

OBITUARY.

Died, December 6th, at Gateshead, aged 62, George Scott, Esq., Surgeon.

December 10th, at Dumfries, James M'Lauchlan, Esq., Surgeon.

December 15th, in Albemarle Street, John Harris, M.D., Fellow of the Royal College of Physicians.

December 17th, at St. Albans, T. Lewis, Esq., Surgeon.

TO CORRESPONDENTS.

Communications have been received from Dr. Oke; Mr. T. Hunt; Dr. J. Taylor; Dr. Denton; Mr. E. O. Spooner; the Birmingham Pathological Society; Mr. J. Allan.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.
